Each of these four programs is developing its demonstration based on its individual philosophy and approach, and in accordance with its operational pattern and legislative responsibility. In each case, however, four basic objectives have been accepted as guiding principles: first, to determine inexpensive and practical methods for reporting nonfatal home accidents; second, to determine the methods and continuing need of in-service education for health department personnel; third, to include home accident prevention techniques and education in all regular health department activities, as an integral part of all functions and operations; and fourth, to evaluate all such activities in the light of their effectiveness, and then determine the relative place of home accident prevention activities in a local health department and the responsibility the health department should accept for home accident prevention. In these demonstrations, the recommended criterion for reportable home accidents is being used in the compilation of statistics on nonfatal home accidents to permit comparison of magnitude and detail of the accident problem as well as evaluation of program effectiveness among the four projects. This in no way precludes epidemiological investigation of any or all home accidents in these project areas.

Thus, four different methods of establishing a base line and compiling data on nonfatal home accidents are being tried. In Kalamazoo, a survey of the entire population, city and county, is conducted annually in conjunction with the school census wherein all homes are visited by enumerators. Home accident cases thus located are checked at a later date by health depart-

ment personnel and the circumstances of each accident are investigated.

In Cambridge, a sample survey is being conducted, in which 1,000 families are visited by health department nurses and sanitation personnel to determine the frequency of, and the various factors involved in, home accidents.

In San Jose, questions regarding home injuries are being incorporated into a morbidity research project conducted under the sponsorship of the California State Health Department. This study of a representative sample of the population will determine the amount of illness in San Jose during a specific period of time. The demonstration program is fortunate in being able to acquire its base line as a byproduct of such a research project.

In Mansfield, Ohio, a survey is planned which will include approximately 25 percent of the families residing in the Mansfield-Richland County area. The interviewing will be conducted by YWCA volunteers trained in interview techniques. The Ohio State Health Department will tabulate the final results.

There are still other methods of collecting data on nonfatal home accidents. A home accident survey made by the public health nurses in Lynn, Mass., was reported by Dr. Helen Roberts of Harvard University. The survey, conducted during 1949-50, was made a part of the nurses' regular duties, so that in the course of home visits, the families were routinely queried as to occurrence of home accidents. Though this study was small, the findings did indicate the kind of information determinable from this type of survey.

Scientifically designed sample surveys will provide representative results of the problems in an area within acceptable reliability. However, such surveys are expensive and ordinarily not undertaken without outside assistance, financial or otherwise, as in the case of the San Jose morbidity research project. However, all health departments can analyze home accident fatality report forms and supplement these findings with inexpensive studies of nonfatal home accidents and with hospital reporting to determine some of the major factors at which preventive measures must be aimed, even though incomplete and not a cross section of the community problem.

Research

The inauguration of demonstration projects and activities in the health departments drew attention to the need for extensive home accident research on problems of major importance to all future activities.

In 1950, the University of Michigan School of Public Health, recognizing the growing interest in home accident problems, the consistently high mortality, the impressive number of accidents attributed to environmental causes, and the insufficient studies of these elements, requested a research grant from the Public Health Service to study the incidence of home accidents, hazards existing in the home, and the accidents themselves. The project was begun in February 1951.

The findings from the study will be related to health department practices, including suggestions for accident investigation, family education in safety practices, and methods of eliminating structural and operational hazards associated with home accidents. An effort will be made to suggest a method for local health departments to design and conduct inexpensive surveys on small random samples that will provide statistically significant figures on incidence.

As studies of types and causes of home accidents and of age distribution were evaluated, it became apparent that further study was needed on specific problems related to accidents among children. The work of Dr. Flanders Dunbar provided initial guidance in reviewing certain aspects. Supplementary knowledge based on studies of injury-prone children was provided by Dr. Elizabeth Fuller of the University of Minnesota Institute of Child Welfare.

The Metropolitan Life Insurance Company made a grant to Dr. Rustin McIntosh to conduct at the Babies Hospital of the Columbia-Presbyterian Medical Center in New York a study of accident proneness in children. The study, now under way, will include a thorough analysis of the history and current status of a number of child accident repeaters and their families, in comparison with a control group relatively free of the accident habit.

Mechanical suffocation of infants is another indication of the need for special studies.

More than 50 percent of the accidental deaths occurring in infants under 1 year have been attributed to mechanical suffocation. Dr. Jacob Werne and Dr. Irene Garrow of New York City studied every infant death from mechanical suffocation reported over a 15-year period in Queens County, N. Y. Their findings indicated that in no instance was mechanical suffocation proved to be the cause of death in a healthy infant, whether by bedclothes or in an analogous manner, but resulted chiefly from pulmonary infections (4).

Dr. Katherine Bain of the Children's Bureau, Federal Security Agency, convened a group of pediatricians, pathologists, and others interested in the problem to discuss steps to be taken to resolve this controversial issue. The group recommended that research studies be undertaken by outstanding pathologists in several large cities to determine actual causes of sudden deaths in infants. Under a Public Health Service grant, Dr. Sidney Farber of Harvard University Medical School, as principal investigator, and Drs. Richard Ford, Jacob Werne, Alan Moritz, and Russell Fisher are working on a research project to "study in a systematic and coordinated fashion a sufficient number of cases of infants dying unexpectedly while in apparent good health, in order to determine the nature of this syndrome and its etiology. Four large cities will be selected initially. In each, all infants between 1 week and 1 year of age dying unexpectedly while apparently in good health will be studied. Each case will have complete pathological studies, including histological and bacteriological, viral studies, and environmental studies. Data will be collected in a similar manner in all centers and will be pooled and evaluated by a central committee."

Recently the American Academy of Pediatrics requested the American Standards Association to set up, under their procedures, a project for the development of standards for equipment, clothing, and other materials which may present accident hazards to children—flammability of textiles, toxicity of paints and household chemicals among others. Plans have been formulated for such an undertaking.

National Programs

Although our present consideration is limited to public health agencies, the contributions of the National Safety Council, Metropolitan Life Insurance Company, and other vitally interested organizations in the field of home accident prevention are numerous and meritorious.

The Subcommittee on Accident Prevention was appointed by the American Public Health Association in 1942. In 1944, the scope of the subcommittee was narrowed to consideration of home accident prevention activities, and in the same year, the subcommittee prepared a paper on recommended activities for each professional discipline in a health department. Since then it has sponsored special home accident prevention sessions at the annual APHA meetings.

Its most recent endeavor was the investigation of the type and amount of home safety education included in the curriculums of schools of public health and public health nursing. The data so far collected indicate an interest in further development of home accident prevention philosophies and methods as an integral part of the over-all curriculum. The information gathered indicates also a wide variety of methods and frequency with which the problem of home accidents is included in a formal educational program. In no instance did a school cover the subject as completely as believed necessary to give the health worker adequate knowledge with which to meet the problem in his own work situation. Recently a task force of the subcommittee has been preparing material to use as curricular guides for schools of public health nursing.

The home accident prevention program of the Public Health Service was inaugurated in 1947 with the assignment of full-time personnel to this activity. Much ground work had been done before then by Public Health Service personnel who had studied the problem while assigned to other activities. Early in the inception of the home accident prevention program, an advisory committee composed of representatives of various Public Health Service functions adaptable to home safety work was appointed

by the chief of the Bureau of State Services to guide development of the objectives, philosophies, responsibilities, and operational activities of the home accident prevention unit in the Division of Sanitation.

The Public Health Service has stimulated interest and activity in home accident prevention among State and local health departments through consultation, public health meetings, guidance in research and demonstration projects, preparation of special survey and training materials, and distribution of packets and brochures. Public Health Service personnel in the Federal Security Agency regional offices, aware of the attitudes toward, and programs of, home accident prevention in the States within their regions, have been active in offering more specific contributions toward planning home accident prevention activities in health departments within their areas.

State and Local Activities and Needs

The home accident problem, although of national scope and importance, will be controlled in essence by the efforts expended at the local level. National or Federal organizations and agencies can correlate and disseminate the results of various undertakings and can suggest the broad but general framework for preventive programs. The State health agencies can make these suggestions more specific for their localities, but the pinpointing of effort must be done in and by the community.

According to current information on home accident prevention activities in health agencies throughout the Nation, 15 State and 13 local health departments have activities in progress. The activities range from the well-rounded program of demonstration projects to modest efforts limited to one professional group within the health department or to one specific activity.

Careful review and analysis of the reports of studies already described have provided information to formulate basic principles of accident prevention. These facts, plus the attitudes of individuals and health groups, and the programs already reported upon or in progress, have given the premise upon which the

philosophy of the Public Health Service in home accident prevention has been built. That philosophy includes the following precepts:

First, home accident prevention is a matter primarily for individuals, families, and community groups. The problem must be met chiefly by the person or group having direct contact with the potential accident victim or his home.

Second, home accident prevention, to be effective, must be a continuous program, aimed at elimination of hazards in the environment and correction of accident-potential characteristics within the individual.

Third, research and investigation into conditions and situations now known to have, or suspected of having, an accident potential should be continued.

Fourth, all home builders, manufacturers, and members of medical, educational, and allied professions should be encouraged to contribute their skills and knowledge to this problem.

The Public Health Service believes that professional public health workers, physicians, and the auxiliary professions must provide leadership and stimulation toward solution of the home accident problem.

Home accident prevention has come out of the laboratory and is now in the development stage. We may look to its integration in all health departments, into every program which seeks to protect the family and the individual in their home environment. In the meantime, there is ample room in the field now for health workers wanting to pioneer in a new territory and to contribute to a new concept of public health.

Epidemiological Techniques in Home Accident Prevention

By HELEN L. ROBERTS, M.D., M.P.H., JOHN E. GORDON, Ph.D., M.D.,
and AUTINO FIORE, M.D., M.P.H.

To consider the application of epidemiological techniques to home accidents is to recognize the altered character of preventive medicine. Twenty years ago, even if sufficient information had been available on which to base control programs, not enough interest could have been aroused in the preventive aspects of cancer, diabetes, rheumatoid arthritis, and mental disorder to make possible active public health programs. The broadened concept of preventive medicine has come now to include not only these chronic diseases, but also injuries of accidental origin (1). Today's concept also presupposes the inclusion of control activities against traumatic injuries as a practical and reasonable part of medical and public health practice.

The Problem of Accidents

Various indices determine the relative emphasis to be placed on leading threats to health. Deaths, disability, defects, and the availability of effective preventive measures are the usual determinants. If deaths alone are considered,

accidents merit serious attention, for, although the total death rate from accidents in the United States decreased from 85.5 per 100,000 population in 1918 to 59.5 in 1950, the relative importance of accidents as a cause of death has increased. In 1950, deaths from accidents ranked fourth in the United States, as compared with sixth position in 1935 (2).

Accidents are classified into four principal groupings according to the place of occurrence—those that happen in homes, at work, in public places, and in association with motor vehicles. Our concern here is with home accidents because they are being accepted as within the particular province of public health and preventive medicine, and because, numerically, accidents in the home make up a very large class.

Cause and Prevention

Home accidents caused over 30.5 percent of all accidental deaths in the United States in 1950. It is estimated that approximately one-half of nonfatal accidental injuries were due to home accidents—4,100,000 of a total of 9,000,000—and that 110,000 persons were left with a permanent physical defect as a result of a home accident. Thus, for every accidental death in the home, 145 persons were temporarily disabled, more than for any other class of accident, and 4 suffered a permanent impairment that varied from a minor handicap to complete crippling. Home accidents alone are ranked ninth among the leading causes of

Dr. Roberts is director of the field training unit and Dr. Gordon is professor of epidemiology in the Harvard School of Public Health. The late Dr. Fiore was commissioner of health of the city of Cambridge Health Department.

This paper was presented before the Subcommittee on Accident Prevention, American Public Health Association, October 31, 1951.

death, according to the National Safety Council (3).

Demographic data such as are mentioned above establish the significance of home accidents as a cause of death, disability, and defect. However, preventive measures and their effectiveness must be evaluated if a case is to be made for the inclusion of home accident control in public health and medical practice. Industry has demonstrated that exact knowledge of industrial accidents will show the way to effective control. All industries reporting to the National Safety Council in 1947-48 revealed a 13-percent decrease in frequency of accidents and a 9-percent decrease in severity of accidents since the base period of 1935-39 (3). Trends in occurrence of certain types of motor vehicle accidents have shown a marked improvement as the result of selective control measures made possible by intensive study of the circumstances of accidents. In Massachusetts, for example, holiday automobile accidents happened twice as often during the evening hours as during the morning hours, even though the same number of drivers were on the road at these two peak periods. Also, specific streets and intersections had higher than average rates. On the basis of this information, police officers were stationed at prescribed places at definite times—with a resultant favorable accident record never before attained on holidays (1).

These control examples in other classes of accidents emphasize that similar epidemiological knowledge of home accidents is yet to be gained. Just as a few centuries ago ignorance of cause led medical practitioners to ascribe disease to demons, so today we blame bad luck or chance for accidents. Accidents have specific causes, just as have the communicable diseases. Public health has long since abandoned blanket control measures as nonproductive and expensive. What is needed is sufficient knowledge of the three interlocking elements in causation—the host, the agent, and the environment—to permit the application of specific, pinpointed preventive measures.

There is no single cause of accidents in general, nor of any one type of accident (1). An approach to the predominant element of cause is made most readily by the method proved useful in the control of communicable diseases and

which is now being applied to chronic diseases—the epidemiological method. As applied to home accidents, the epidemiological approach is simply the collection and analysis of all the facts about accidents in a given community—when and where home accidents occur, how they occur, and to whom the accidents happen (4).

Methodology of Mass Study

To date, our epidemiological approach to cause in home accidents has suffered from several mistakes in methodology which have made sincere efforts of limited value. First, too great emphasis has been placed on analysis of deaths from accidents. Important as this analysis is, it ignores the critical information to be obtained from the study of nonfatal accidents. If the epidemiological study of diphtheria had depended solely on autopsy findings and the circumstances of deaths from diphtheria, our present knowledge would be sadly deficient. Accidents, too, show a gradient of disease or injury as a result of a prescribed exciting cause—a similar occurrence may lead to loss of life in one individual and, in another, to no more than a loss of equanimity. Only a concerted study of all accidents—those resulting in minor injuries as well as those with major sequelae—will permit a real knowledge of cause.

Second, too many facts about accidents have been gathered haphazardly without well-defined epidemiological objectives, and have been put together with no regard for the varying predominance among causative factors, of the behavior and characteristics of the person suffering the accident, the site of the accident, and the immediate agent giving rise to the event.

Third, in formulating local control programs, too great dependence has been placed on national statistics. Home accidents vary from community to community, depending upon occupation, age of population, housing, economic resources, geographic area, and many other factors. General principles in analysis and prevention may be similar in different areas, but only concentration upon its own home accident occurrence will enable an area, a city, or a State to define its individual situation and thus apply specific control measures.

The task, therefore, is to evolve practical methods that can be used by an individual community to determine the causes of its home accidents. Upon a firm basis of epidemiological knowledge of the disease, control can be built.

There are, of course, a number of ways of going about the epidemiological investigation of home accidents, especially those that are not fatal. There are, also, practical limitations of time, personnel, and funds which face the health department and other community groups which wish to move forward in this important sector.

Experience suggests that when substantial funds are not available, the studies that can be undertaken are limited to such things as collection and analyses of mortality statistics, hospital records, and reports obtained by nurses and sanitarians in the course of their routine visits to the homes in the community. Certainly these inexpensive studies are not complete, nor a cross section of a community problem, but they are indicative of some of the major factors at which preventive measures must be aimed. Any sample survey large enough to be statistically significant within the variance desired becomes an expensive item and, in most cases, can be undertaken only by a few health agencies fortunate enough to obtain supplementary funds for such a project.

Several of the more promising epidemiological approaches to home accidents are described in the following paragraphs. We have had experience in the use of several of these techniques in the community, and others are now being tested.

Mortality Analysis

Although we have criticized the restriction of epidemiological studies of home accidents to mortality data, we do not deny their importance. As a matter of fact, this is a logical point of departure for the community wishing to know the facts concerning accidents occurring locally.

A statistical analysis of accidental deaths during the past 10 years, compiled from death certificates, forms an essential base line for future evaluation of control programs as well as giving some indication of serious hazards in

the area. A continuing record of home accident deaths as they occur in the community should be maintained by the health department. Information contained on death certificates is insufficient for this purpose. The State of Kansas and Nassau County (New York) have demonstrated that information about all the circumstances of a fatal home accident, collected from families, physicians, and others concerned with a case, adds immeasurably to epidemiological evaluation.

The "Home Accident Fatality Report," prepared by the National Office of Vital Statistics, Public Health Service, is an important means of developing systematic information on home accident deaths.

Definitions and Terminology

The design of a study of nonfatal injuries in a community involves serious consideration of and decision on several perplexing definitions. For example, what is an accident? A dictionary definition is insufficient. Shall intention rule out a case? Most of us consciously take actions fraught with calculated or undefined but appreciated risk. How shall we dispose of the unsafe act resulting in no injury? Shall resultant injury determine the occurrence of an accident? And, if so, how shall "injury" be defined?

The National Safety Council's definition of an accident excludes any event which results in disability of less than 1 day. Use of this definition has led to uncertainty in many cases. For instance, age greatly influences disability resulting from accidents. A prescribed event may disable an elderly lady for a week or more, but at most may only inconvenience a young child. Furthermore, occupation may determine the degree of disability. An executive who fractures a metacarpal may not miss a day's work. He is able to dictate his letters as usual, but such an injury is incapacitating to a typist in his office.

Other terms requiring definition are: the home; the usual place of residence; the determination of duration of risk in the home; the inclusion of visitors in the list of persons exposed to risk; and indices of economic status and reliability of informants.

Each of these terms needs to be defined prior to an individual study, even though no universal definitions are sought. The important consideration, if confusion is to be avoided, is clarity in definition of terms and agreement among all workers on the type of information to be included before actual collection of facts is undertaken.

Studies of Nonfatal Accidents

The kind of study selected by the community to determine the epidemiological facts of nonfatal accidents will depend on the method of finding cases, and upon the finances and personnel available. The survey may include only one or a combination of case-finding methods.

Hospital Admissions

Community hospitals in many areas are most cooperative in aiding health departments in home accident studies. A continuing study of admissions to out-patient treatment and to in-patient wards may profitably be utilized to assess the circumstances of more serious home accidents. Hospital records alone usually do not supply the needed epidemiological data, but can be enlarged by an accident history obtained from the patient or from a member of his family, by study of the site of the accident, and by cooperation of the attending physician.

The number of accidents and the relative gravity of the injuries suffered by patients admitted to hospitals will vary from one community to another, depending on availability of hospital facilities, economic status of the population, and customs of the community in seeking hospital treatment. However, a sample drawn from hospital admissions is always highly selective and is not representative of all home accidents occurring in the community. To study hospital admissions alone, as to study deaths alone, is to underrate greatly the medical, economic, and social seriousness of the problem (4).

Health Department Routine Activities

A reasonable compromise in epidemiological technique for the health department with limited funds and personnel is to include a home accident survey in the activities of health de-

partment employees making routine visits to homes. If other surveys, such as housing, are being conducted by the health department, home accident investigations may easily be added, and may be carried on by the personnel doing the primary survey.

Even better, however, is to have the nurses of the health department and visiting nurse association include—as part of their regular home visit procedure—questions about accidents occurring in the home during the past month. Although a sample drawn from clients of public health nurses rarely will be representative of the total population of the community, this disadvantage is balanced to some extent by extensive knowledge of accidents that occur in that portion of the population in which the health department subsequently may be conducting an accident control program (5).

In certain areas in Massachusetts, nonprofessional personnel have been used for studies of this type. We have not accumulated sufficient experience to show the relative value of data so collected and data obtained by professional workers.

A convenient form for recording epidemiological data is used. The household roster is used to calculate the number of persons at risk. All survey workers must be fully informed about the accident problem, the objectives of the study, the definition of terms, and the use of the record form. Each investigator should be provided with a code to the record form.

Extensive Study of Home Accidents

The objective in an extensive study of home accidents is to determine the distribution of accidents in a representative sample of the population, and the controllable causative factors in accident events. Professional investigators are utilized in such a study. Since only one visit is made to designated households, only information on major home accidents is sought. A practical criterion of gravity of injury is whether or not the person was under medical care.

The purpose of this type of study is to provide basic facts about the home, the family, and major home accidents during the preceding

year. Additionally, the information obtained is perhaps the best guide in selecting a sample for the intensive type of study next described.

Granted an adequate sample, the accident prevention program may be planned on information collected in the first year of the study. Continued observations over a 3- to 5-year period would add to knowledge of causation, and, most importantly, serve to evaluate the accomplishments of control measures. However, this approach—as in the case of the intensive investigation described below—requires a substantial investment in time and funds for study design, field work, and analysis and interpretation.

Intensive Study of Causation

Essentially nothing is known to account for the frequency of home accidents in a given population. No adequate data are available concerning the characteristics of the population at risk, the actions and characteristics of the victims of accidents, and technical analysis of the environment in which accidents did and did not occur.

A study designed to obtain data and to assess these features in accident causation would include periodic visits to selected families. Ideally, the group would be made up of a random sample, but a more practical aim is a smaller sample, obtained by stratification or other means to assure that it will be closely representative of the community. The size of the sample is determined by numbers of available investigators—possibly including public health nurses and sanitarians, the frequency of observations, the bulk and variety of information desired, and the limits of variance that will be acceptable in the final results.

The interval between visits is necessarily short if the objective is to record all unforeseen events resulting in physical injury, as determined by specific signs or symptoms. The householder's memory of minor injuries is limited.

Since this type of study is based on the family, transient visitors are excluded, because the essential data on units of exposure to risk is difficult to obtain. However, visitors in the household who spend a period of time equivalent to the interval between inquiries or accidents are included.

Summary and Conclusions

A case is presented for the inclusion of home accident prevention as a major activity of health departments and physicians. The argument rests upon the accident toll in terms of death, disability, and defect.

Specifically directed prevention based on an understanding of cause has proved effective in communicable disease control and is now being utilized in chronic diseases. The epidemiological method of analysis of multiple causation is a recognized part of the study of mass disease and the practice of public health. It should be recognized equally in the approach to mass injuries as a community health problem.

Several techniques of epidemiological study of home accidents are presented as a means to better understanding of home accident causation, and hence, an improved record in deaths, disabilities, and economic loss for the community.

Have You an Idea?

Something new? Different? Better? An easier way to get a job done? A simpler approach? More efficient? Cheaper? Faster?

As a health officer, hospital administrator, nurse, sanitarian, health educator—whatever your position—the day-to-day problems you face more than likely have counterparts in many other places. How you tackle your tasks may be of very real help to others in similar situations. And notes on how they handle their problems may help you.

This "Ideas" section is a place to exchange experiences and approaches. You, as well as your colleagues, will benefit when you send in your ideas.

—THE EDITORS

Council on Mental Health

GEORGIA. An interagency council on mental health has been formed to join avenues of cooperation in meeting mental health needs. The State departments of welfare, education, higher learning, vocational rehabilitation, prisons and corrections, health, employment, and others are usually represented. Participants take turns at being host. Liaison between agencies is discussed and mutual problems shared in the hope that solutions may be worked out more readily.

At one meeting the group worked on a plan for a general statement of their collective mental health needs to be presented to the Citizens' Council and then channeled out to the employees of the organizations represented. In this way, the statement would eventually reach some

20,000 teachers, health workers, and government workers, informing them of the needs and the plans to meet those needs being developed jointly by the official agencies of the State.

Rural School Health

CLINTONDALE, N. Y. A teacher at the Tri-horough School asked a public health nurse for help in including health in her teaching. A public health educator was called in and met with a student-teacher committee. The school's interests were many: safety, good breakfasts, personal hygiene. The students wanted to be "doing things," and a school health program seemed to tie in with 4-H projects in the health field. So Miss Louise Archibald, assistant county 4-H agent, became a part of the planning committee.

Monthly programs began at the school in December. The first meeting concerned nutrition. Films followed by group discussions roused interest. Teachers extended the idea into the classroom along with reading, writing, and arithmetic. The student planning committee decided they would like to prove to themselves that eating the right food pays. Rat feeding demonstrations were begun in the classroom. The program is expanding into all age groups, and the planning group is formulating a long-range health program for their school which will branch out in the community.

Ring Testing in Cattle

MINNESOTA. Three mobile laboratories are being used for a cattle ring testing program in the 53 Minnesota counties not included in the State's "area plan" for controlling brucellosis, or Bang's disease.

The area plan, already operative in the other 34 Minnesota counties, provides for the systematic blood testing of cattle after a petition has been signed by at least 67 percent of a county's cattle owners and accepted by the State livestock sanitary board.

Ring testing is an effective screening device in those counties not under the systematic blood testing plan. The mobile units receive, and test milk samples collected from dairy herds without charge to the herd owner. When the ring test is found to be positive, suggesting that brucellosis may be present, owners are advised to have all cattle blood tested individually by veterinarians to discover diseased animals.

So far the program has covered 14 of the 53 counties, and approximately 25 percent of the milk samples tested have suggested the presence of brucellosis.

Not at Home?

OKLAHOMA. In his round of dairy farm inspections, the milk sanitarian cannot always contact the dairyman at the time of inspection to discuss violations. The most effective inspections are those where the sanitarian can discuss first the crops and the weather and then the dairy items needing correction. On nearly half of his inspections, the sanitarian finds that the farmer is either not at home or working in the fields. Often when an inspection is made, and the inspection sheet thumbtacked to the milkhouse wall, the dairyman may not notice it for days. If the sheet is left on the cooler, contrary to the standard milk ordinance, the dairyman or his wife may see it, but it soon becomes lost, possibly before the necessary corrections have been made.

At least one Oklahoma State sanitarian increases the value of his "not-at-home" inspections by using this procedure:

If milkstone is found on milker heads, strainers, pails, or other utensils, this information is noted with a red wax pencil on the outside of the utensil. Notes on half sheets of paper are laid on, or thumbtacked near, such violations as dirty teat cups, a torn screen, or unused equipment stored in the milkhouse. Although the inspection sheet is self-explanatory, there is little or no space for writing in comments or details of violations—but the plan

pointing of violations makes it easier for the dairy farmer to locate and correct such violations.

Dishwashing Efficiency

CONNECTICUT. A mobile laboratory has been checking dishwashing efficiency in local Connecticut eating places since December 1949 as a part of the State's education program in restaurant sanitation.

The itinerary of the laboratory trailer is planned for several months in advance to coincide with local meetings of restaurant proprietors, their employees, and local health department personnel. The fundamental principles of food sanitation are stressed at the well-attended meetings, which are held in an atmosphere of friendliness. Talks, movies, leaflets on sanitary food handling and cleansing of eating utensils are featured. Displays of actual bacteria growth from samples obtained at local restaurants point home the necessity for cleanliness.

Prior to a meeting, a laboratory technician, working in the trailer, makes a swab test to indicate the number of bacteria on eating utensils. The same tests are part of the routine inspection of each eating establishment when a trailer is located for serving a town.

The swab test is a good index of the efficiency of the washing and bactericidal processes used in a restaurant. A sample is obtained from five swabbings made on five different eating utensils—glasses, cups, cutlery—using a piece of sterile cotton to swab the inside and outside edges of each utensil three times and transferring all bacteria collected to an iced sterile solution. A portion of the sample solution is then tested in the trailer laboratory where an advantage lies in immediate processing before final laboratory testing.

The two photographs on this page of the interior and exterior of the laboratory illustrate two major educational functions it performs as part of the Connecticut restaurant sanitation program: how the technician works at his job; what type of improved equipment the health department recommends.

A bacteria count of swab-test samples obtained from restaurants is made by bacteriologist working in trailer laboratory. Bacteria counts at 98.6° F. are considered satisfactory if below 100. Counts between 100 and 500 are high. Counts over 500 are excessive and call for improved equipment and procedures. The trailer technique provides an advantage by making possible immediate processing before final laboratory testing.

Large side panel on exterior of mobile laboratory illustrates type of sink recommended in the Connecticut restaurant-sanitation program. Other educational aspects of the program stress short conferences for food handlers in towns visited by the laboratory.

State Nursing Surveys and Community Action

By FAYE G. ABDELLAH, R.N., M.A.

During the past 6 years, 35 States and the Territory of Hawaii have used the nursing survey as a tool in analyzing state-wide nursing needs and in alleviating nurse shortages.

Here are some of the major findings revealed by these surveys:

All surveyed States were found to have acute professional nurse shortages and were unable to provide the desirable number of professional nursing hours to patients.

The greatest numerical shortages were found in general hospitals.

The highest need per patient was found in mental and tuberculosis hospitals (see table).

The availability of public health nursing services ranged from none in some communities to adequate coverage in others.

All States revealed that only the very large industrial plant offered nursing services to industrial workers.

Lack of prepared teaching personnel is the most acute problem facing the States. The thin spread of student enrollments throughout the schools suggests an uneconomical use of teaching facilities.

Many students were found to have had no experience in tuberculosis, psychiatric, or public health nursing.

Hospitals, faced with the necessity of providing adequate nursing coverage, have employed many nurses with limited preparation in positions above staff level. Few teaching personnel, public health and industrial nurses were found to have the preparation needed for

their positions. Opportunities to obtain this training were not accessible to nurses who had to carry full-time jobs.

State Surveys Started

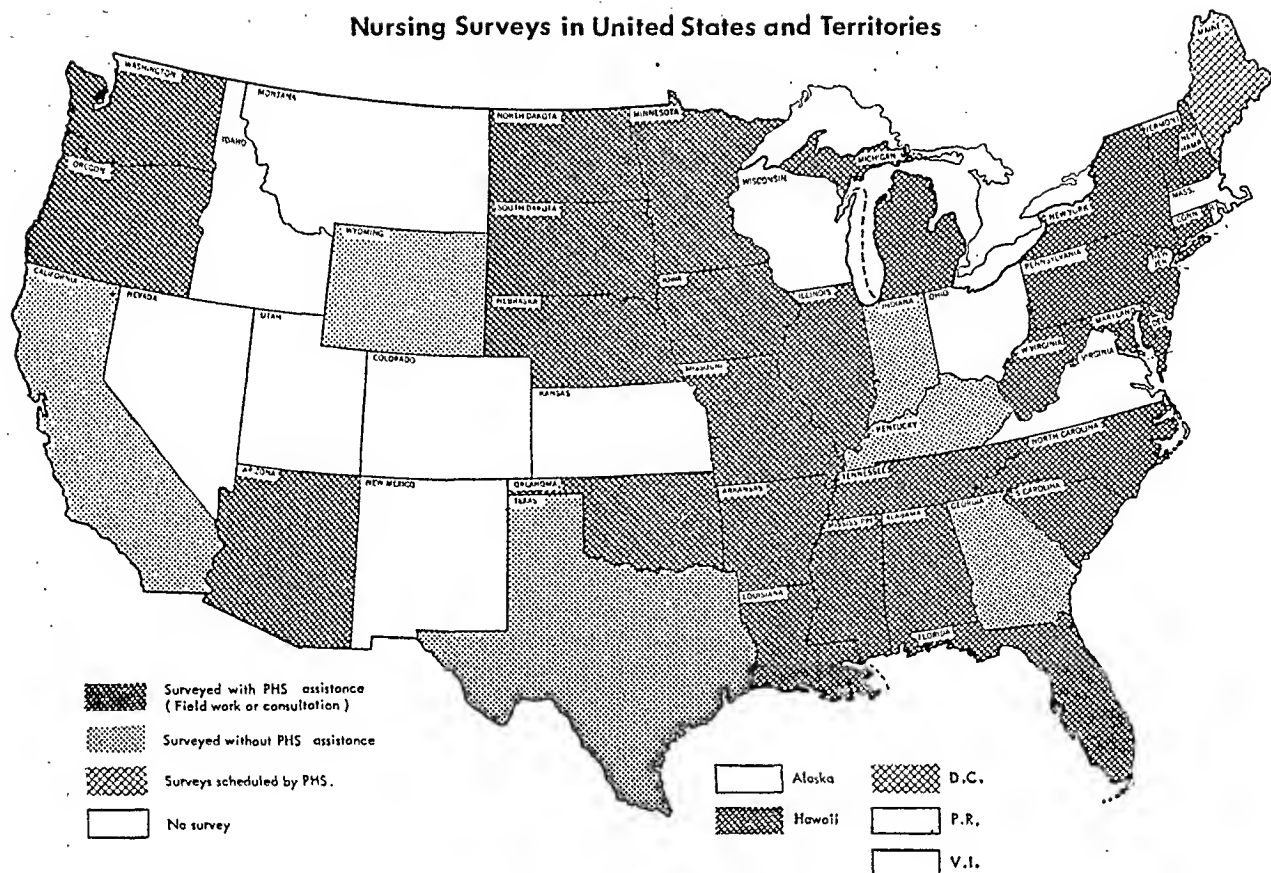

As early as 1946, individual States began to study why the nurse supply has not kept up with the demand and how to meet the nursing needs of the people. Impetus to study state-wide nursing needs was given in 1943 when the National Nursing Council for War Service took the initial step in attacking the problem by appointing a Committee on Domestic Postwar Planning, later to become the National Nursing Planning Committee. It set as its objective the development and distribution of nursing services to the people as well as strengthening nursing education programs (1).

Recognizing the need for these studies, the Public Health Service published a manual in 1949 to guide interested States in conducting nursing surveys (2). The Public Health Service has also directed the field phase of the surveys or provided consultative service in 28 States and in Hawaii. Six other States have conducted nursing surveys without Public Health Service assistance. The accompanying figure identifies these States as well as those where surveys are scheduled.

Only 19 of the States surveyed (with Public Health Service assistance) provided data for analysis. The weaknesses uncovered in these 19 surveys are being attacked by specific programs which have been developed with citizen support following survey recommendations. It was felt that an analysis which would show the steps taken in the surveyed States to find their solutions to nursing problems, as well as addi-

Miss Abdellah is a nurse consultant with the Division of Nursing Resources, Bureau of Medical Services, Public Health Service.

Nursing Surveys in United States and Territories

tional steps which need to be taken in States only recently surveyed, might be useful in planning similar surveys or follow-up evaluations. Therefore, findings, progress activities, and conclusions are based on the 19 comparable surveys.

Organizing a Survey

The organization set up to operate the surveys was planned around State survey committees. Here a common pattern developed where the individual survey committees conducted the actual surveys which were originated by the State nursing groups alone or jointly with legislative or governors' commissions, State universities, or citizen groups. Members of the committees included representatives from both nursing organizations and such nonnursing groups as medical societies, educational associations, labor organizations, industry, and women's clubs.

No one State followed any one organizational pattern throughout the entire series of surveys.

In Louisiana, for example, nursing organizations formed a Joint Committee for the Improvement of Nursing Services to sponsor its survey and appoint committees in conjunction with the State department of health and the State hospital board.

In 15 States, the State health department joined with State nursing organizations in initiating nursing surveys. South Carolina typifies this joint endeavor. There the State department of health not only sponsored the survey in cooperation with the nursing organizations but also provided office space for the survey director and assigned nurse personnel to participate in the survey.

In some few instances a State university or a women's club initiated a survey. Realizing that the scope of the project would require the services of a full-time director experienced in conducting surveys, these groups sought the assistance of the Public Health Service.

A nurse consultant was assigned by the Division of Nursing Resources of the Public Health Service to assist State committees in

conducting each survey by lending it general direction, supervising the collection of data, and participating in the preparation of the survey report. Nurses in the State took the leadership in organizing committees and in deciding what professional standards to use in estimating needs, and then turned from this organizational phase to the collection of information. Before undertaking the field phase of the survey, the State committees agreed, after discus-

sions, on the specific purposes and emphasis of the survey, and distributed the workload. The final recommendations for action came from these participating committees.

Emphasis of Surveys

All surveys had three major purposes:

1. Determine if there are enough nurses available in each field of nursing practice to meet the needs of the State.

Professional nurse needs, supply and deficits, in hospitals, by type, in 18 States and one Territory following similar survey patterns during survey years, 1946-47, 1948, 1949, and 1950

¹ The figures for individual States are not additive. ² Needs for nurses are based on standards accepted by the survey committees. These standards vary from State to State so that estimates of needs for the different States are not comparable. ³ Supply data are obtained from State boards of nurse examiner's Registers of Licensed Professional Nurses, from surveys of hospitals, and from surveys of individual nurses. In general hospitals, the supply figures have been adjusted to include the services provided by student nurses. ⁴ Data are missing. ⁵ These figures are excess.

2. Ascertain if the present facilities for nursing education can produce enough well-prepared nurses.

3. Determine if graduate nurses in hospitals, schools of nursing, public health, and industry are trained for the jobs which they are performing.

Other purposes were directed toward finding solutions to such problems in the field of basic professional and graduate nursing education as "Determine if there is a need for establishing a collegiate school of nursing."

Survey Recommendations

Strikingly similar are the recommendations evolving from the surveys. All States including Hawaii stressed the need for additional professional nurses and the need for better prepared professional and nonprofessional nursing personnel. All States stressed broader experience in tuberculosis nursing. Eighteen States wanted more experience in psychiatric nursing for student nurses; 12 stressed centralization of instruction in the basic schools of nursing; 18 stressed the need for workshops, institutes, and extension courses for graduate nurses; and 16 recommended a continuing committee to plan, coordinate, and promote efforts to improve nursing in their States. These were the recommendations which formed the basis for postsurvey study, planning, and action.

In order to promote and carry out the survey recommendations, all of the 19 States formed new committees composed of the original committee members who participated in the surveys. In some cases, new members having special knowledge of the problems requiring solution were included.

Postsurvey Activity

The activity following a nursing survey has varied from State to State. The greatest progress toward achieving survey goals was made in the 13 States where citizens and citizen leaders, in addition to nurses, planned the early stages of the survey and followed through on the postsurvey recommendations. Fifteen States have presented the facts and problems revealed in their surveys to the public, asking for support in finding solutions. Broad com-

munity participation and presentation of the problems to the public have apparently stimulated action following a survey.

Specific progress can be seen in States where problems defined by the survey called for immediate action by nursing groups. For example, in Washington a refresher course has been organized for the 2,700 practical nurses licensed by waiver.

Solutions requiring cooperative action by nursing and other groups take longer to achieve, although achievements of this type have already been recorded. One example is the provision of scholarship assistance for student and graduate nurses by legislatures, and another is the promotion and provision of nursing services for industrial workers in small plants.

Public Health Nurses

The ratio of public health nurses to population is affected by population changes and the total number of public health nurses employed. Twelve of the 19 States not only have increased the number of public health nurses employed but also have increased this number proportionately more than the average for the United States. Four additional States, while increasing the number of public health nurses, have not kept pace with the national rate of increase of public health nurses to population. Three other States have lost public health nurses. In an independent review of State programs by the Public Health Service it is indicated that this loss can be attributed to budget curtailments and to more favorable opportunities opening in other States.

Eleven States, since their nursing surveys, have increased the proportion of public health nurses who had completed one or more years in an approved public health program, and three have surpassed the average relative increase rate for the United States. Three other States show no change since the year of survey.

Five States have a smaller proportion of prepared public health nurses in comparison to the survey year. Three of these States are near or well above the national ratio for 1951 of 35.3 percent of prepared public health nurses. A review of State programs also indicated that some States employ graduates of 3-year schools

on a temporary basis to increase the coverage of public health nurses to population. Many States have increased markedly the total number of public health nurses and are faced with the task of preparing more nurses. When such nurses are given an opportunity to qualify as public health nurses, the total number of prepared public health nurses in these States will increase.

Student Training Widened

Nurses coordinating their efforts with citizen groups have successfully provided broader experience for student nurses in 13 States in the postsurvey periods as shown below:

Affiliation Added			
Total	Rural	Tuberculosis or communicable disease	Psychiatric
6	7	9	
Arizona			x
Illinois			x
Louisiana		x	x
Michigan	x		x
Mississippi		x	x
Minnesota	x		
Oklahoma		x	
Oregon	x	x	
South Carolina		x	x
South Dakota	x		x
Tennessee	x	x	x
Washington	x		
West Virginia		x	x

Seven States where students formerly were given limited experience in tuberculosis nursing, or none at all, have since their surveys developed new affiliations in tuberculosis nursing or have provided this experience to a larger number of students. In addition, nine States which provided psychiatric nursing experience in mental hospitals out of State can now offer this experience within their borders and extend it to more students.

South Dakota had such a problem. Its survey recommended broader experience for student nurses in psychiatric nursing. The nurses wanted to set up a State hospital affiliation but could not achieve this until the funds were available. So a joint hospital and State committee of nurses and others was organized. Through the committee's well-coordinated efforts, legislation was passed appropriating \$110,000 for the establishment of an affiliate school of nursing at the Yankton State Hos-

pital. Now, for the first time, student nurses in South Dakota can obtain psychiatric nursing experience within their State.

Six States are providing experience in rural hospital community nursing for the first time where only limited field experience in public health nursing had been offered in the past.

Collegiate Schools of Nursing

Of five States recommending the establishment of a collegiate school of nursing, three have actually established these schools, and two other States are in the process of establishing them. One State recommended deferring the formation of a collegiate school of nursing until a sufficient number of faculty and supervisory personnel have been prepared for participation in such a program.

Legislatures Provide Scholarships

One encouraging step the States have taken to increase their nurse supply and to provide graduate nurses with special training is the appropriation of funds for nursing education. Three of the 19 States—Minnesota, Mississippi, and South Dakota—through their legislatures have provided direct financial aid to professional nursing schools or scholarships for students (3).

In 1948 the Mississippi State Legislature appropriated \$60,000 for a nursing education program at the University of Mississippi and in 1950 appropriated \$115,000. Scholarships amounting to \$85,000 were awarded in 1948 to professional registered nurses who wished to obtain advanced preparation in colleges or universities. This appropriation was later increased to \$96,400. To date, 20 of the recipients of the 32 scholarships awarded have returned to Mississippi and are now in administrative and teaching positions; the other 12 are still enrolled in collegiate or university programs. Part of the State appropriation went to employ a full-time instructor for extension courses in ward management and clinical teaching.

New Opportunities for Graduates

Eleven States offering only limited opportunities for postgraduate education have developed new opportunities for graduate nurses to contribute to better patient care as shown here:

Educational Programs

	<i>Extension courses for credit</i>	<i>Work- shops or institutes</i>
Total.....	10	11
Arizona.....	x	x
Florida.....	x	x
Illinois.....	x	x
Louisiana.....	x	-----
Michigan.....	x	x
Mississippi.....	x	x
New Jersey.....	x	x
Oklahoma.....	x	x
South Carolina.....	x	x
Tennessee.....	-----	x
Washington.....	-----	x
West Virginia.....	x	x

Nine States have set up extension courses for credit and workshops or institutes; one has set up extension courses for credit but without a workshop or institute; and two additional States have set up workshops alone.

West Virginia met the problem of improving its schools of nursing by offering a 2-day workshop in "Curriculum Construction and Revision in Schools of Nursing." West Virginia University, the nursing organizations, and the State Health Department all contributed personnel to conduct the workshop. Sixty nurses, representing 11 of the schools of nursing, hospitals, and public health organizations attended. The enthusiastic response to West Virginia's workshop has spurred the development of other workshops and extension courses for graduate nurses in the State.

Arizona is offering for the first time an accredited course in "Principles in Public Health Nursing" which was instituted following the response of 600 active and inactive nurses to a questionnaire poll. Eighty nurses are now enrolled in two centers.

Programs for Practical Nurses

Following nursing surveys, five States set up eight new programs for practical nurse training in public vocational schools. Illinois, Tennessee, and Oklahoma used their survey data successfully in supporting legislation for licensing practical nurses. Legislation for the practical nurse has been recommended in seven other States.

Areas of Future Progress

Too short a time has elapsed since the surveys were completed to permit a measurement

and an evaluation of changes in the total nurse supply and in the number of nurses graduating, receiving postgraduate preparation, or providing part-time service to industry. Post-survey trends can best be analyzed after the data of the years to come have been accumulated. To increase the total nurse supply, to prepare additional nurses for teaching positions, public health and industrial nursing, and to extend nursing services to industry are the goals ahead which need broad community participation for their achievement.

Increasing the Supply

Specific progress in attaining an adequate nurse supply, both quantitative and qualitative, calls for varied but related activities: stepping up nurse recruitment, improving basic schools of nursing, and overhauling personnel policies. Little progress can be achieved by nurses working alone. The 19 surveys have intensified the necessity for joint effort—by laymen and nurses.

Graduation Trends

A longer period of time is necessary for studying graduation trends. In five States where there has been a lapse of three years since the completion of the surveys, the number of nurse graduations is greater than the United States average. But it must be pointed out that admissions to these schools were made prior to the survey year and cannot be attributed directly to the survey. As student withdrawal rates are reduced by the adoption of more selective and better counseling techniques, and the number of admissions remains constant, it can be expected that the increase in graduations will produce a greater nurse supply.

Key Positions

No information is available on the preparation of hospital nurses for positions above staff level. Only five States have collected data in this area. Before any progress can be analyzed, here too, original data must be collected on a continuing basis, as is done in the public health nursing field.

Part-Time Service in Industry

The surveys revealed that 13 States have limited or no nursing services available for the

small industrial plant with 100 or fewer employees. It has been successfully demonstrated that part-time nursing services can be provided by a visiting nurse association or local health department, or by sharing the services of a nurse in more than one plant (4). This is a long-range goal, for when a nurse's services are provided by a local visiting nurse association or department of health, administrative changes in the organization providing part-time nursing service are usually involved. Other factors to be considered are the development of an informational and educational program focused on a better understanding by management and employers of the contribution nurses can make to industry. Contractual arrangements with industrial plants must be worked out and nurses obtained to staff the projects. This too is an area in which citizens and nurses must work together to achieve a common goal.

Conclusions

With the increased demand for nursing services, States analyzed their nursing programs, carefully measured their needs for nursing personnel, and evaluated their educational programs in terms of future nursing services for their communities.

Hospital and nursing administrators have had to plan the number and kinds of nurses required to sustain professional services and to decide whether they were using their staff nurses most effectively.

When the loss every year of many nurses from the profession is coupled with the low admissions and high withdrawal rates in schools of nursing, an even greater challenge faces the nursing profession in meeting the nursing needs of the States. Now is the time for citizens and nurses to continue organizing groups to make comprehensive long-range plans for meeting the nursing needs of the citizens. A state-wide nursing survey provides a basis

for the preparation of a flexible plan for nursing.

As States progress toward survey goals, each forward step contributes to the national nursing picture. As steps are taken to improve the nursing program of one State, no matter how small the program, the nursing profession will benefit. Better and more nursing service for the families and communities of a State will not only improve its level of health but will also increase its share in national production. Greater progress will become more apparent as citizens with widespread interest continue working with nursing organizations on the immediate problems of recruitment, staffing, education, and training.

Much more study must be made of how nurses can work with other groups on related research, including the collection of original data, and of how they can assist in the development of regional and State planning for nursing.

Progress will be made in direct proportion to the degree of unity and agreement which can be achieved by groups sharing a common interest in nursing. A nursing survey can be a constructive device for getting community action. It provides an opportunity for nurses and community representatives to discuss nursing problems by sharing leadership and responsibility. A state-wide nursing survey can thus become a pattern for a comprehensive nursing plan. The action it generates will achieve better health for all.

Malaria Blood Survey Of Mexican Laborers In an Arkansas County

By L. KARTMAN, Sc.D.
BETTYE M. MAYS, R.N.

Mexicans have been employed as transient agricultural laborers in the Mississippi Delta area since 1925. The number of such workers has been increasing, and the legislation approved in July 1951 (1) concerning the use of Mexican labor in the United States will allow thousands more of these laborers to come into this country every year. In former years, many of these workers were residents of Texas, but recently most of them have been male Mexican nationals coming into the United States from many of the Mexican States. These workers are given medical examinations and are vaccinated against smallpox (2), but examinations of blood films for detection of malarial infections are not routinely performed. Since endemic malaria continues to be reported from many sections of Mexico (3) and since the imported laborers are exposed to large populations of *Anopheles quadrimaculatus* in areas in which they work, it was considered desirable to determine if such persons employed in Phillips County, Arkansas, carried malarial parasites.

Methods

Thick blood films were made from workers in the cotton fields by a three-member survey team. Each group of workers usually had an interpreter. It was possible to call up four or five men at a time, obtain their names, ages, and

Dr. Kartman, an entomologist with the Communicable Disease Center of the Public Health Service and now in charge of the Hawaii Field Station, Honokaa, T. H., previously participated with Miss Mays in a mosquito and malaria investigational project in Arkansas.

other pertinent information, and to make the blood films in about 1 to 2 minutes per man. This was facilitated by having the interpreter or one of the workers act as recorder under the direction of one member of the survey team. The other members of the team made the blood films.

Malarial Survey Findings

A total of 1,038 blood films was obtained on the Mexican nationals from June 5 through July 12, 1951, and 1,022 of these were examined for malarial parasites. These 1,022 represented over 94 percent of the 1,080 Mexican workers under contract with plantations in the Phillips County Cotton Growers Association. The workers contacted represented 24 Mexican States and the Federal District. The majority of these men were between 20 and 35 years of age. An attempt to obtain histories of malaria proved difficult since questions concerning disease or physical disability were generally evaded. Nevertheless, some data were obtained. The table shows the distribution of the men according to the 24 Mexican States from which they migrated and recent malarial morbidity and mortality rates in Mexico.

Five percent of the men gave positive histories of malaria but the blood films were negative for parasites. Obviously the histories of malaria represent a small fraction of the true past positives for malaria among the men surveyed. However, the data in the table indicate that men from Mexican States with higher morbidity and mortality rates gave more positive histories than those from the Mexican States with lower morbidity and mortality rates.

Mexican workers have been shown in the past to constitute a source of malarial infections. However, these records are based primarily on Mexicans living within the United States (4, 5). No past records exist on infections due to malaria of Mexican nationals brought into this country.

Recent Communicable Disease Center malaria appraisal data show that in 1949, 8 cases appraised as positive occurred in Texas among Mexican nationals and in 1950, 13 such cases were identified. Each of these cases occurred as sporadic individual cases; none were known

² Baja California, South Territory.

to be identified in groups of two or more, which suggests that they represent relapses of infections acquired in Mexico rather than spread of the infection within the United States.

Summary and Conclusion

In view of the paucity of available records of malaria among the Mexican nationals brought into this country, a blood survey of 1,038 Mexican nationals in Phillips County, Arkansas, was accomplished. The fact that not a single positive blood film was found may suggest that there is little danger of transmissible malaria from these nationals. Nevertheless, as long as many of these workers are recruited from Mexican States from which endemic malaria is reported, it might be advisable for border stations to obtain blood films from individuals who give a recent history of malaria, or who exhibit clinical symptoms of malaria.

Small-Quantity Blood Tests for Syphilis

The procedures reported in the five papers that follow have been developed in response to a need for methods of examining the blood of infants for syphilis when it is impracticable to draw the quantities required for standard serologic tests. Also, a technique is needed to mail samples long distances under particularly adverse conditions.

The techniques described present difficulties in securing suitable samples, and in comparative tests all have shown a lower sensitivity than the conventional serologic tests. However, with these techniques, serologic tests for syphilis may be performed on certain patients and under conditions which would completely preclude testing by conventional means. The results suggest the need for further study to determine whether, under special circumstances, the tests may be useful or whether the techniques can be improved.

A Comparison Of Serologic Tests

By SIDNEY OLANSKY, M.D.
AD. HARRIS, HULDA VINSON, B.S.
HILFRED N. BOSSAK, B.S.
JOSEPH PORTNOY, M.S.

At the direction of the office of the chief, Division of Venereal Disease, Public Health Service, a study to determine the relative efficiency of tests for syphilis requiring small amounts of blood, such as could be collected by finger puncture, was organized. Results of an evaluation of the FPM tests (1) and a preliminary study of the Chediak test (2) have been reported. A modification of the Chediak

test using cardiolipin-lecithin antigen is described in the latter report (page 572 of this issue of *Public Health Reports*).

Study of the Chediak tests has been extended to include several testing centers. The purpose of this article is to present and discuss data and information obtained during this study as they relate to the relative efficiency of: (a) the Chediak test, (b) several modifications of this method for testing dried whole blood, and (c) a micromodification of the VDRL slide test by Cannefax and Johnwick (3) compared with other serologic tests for syphilis performed on heated serum. The laboratories of Dr. R. L. Kahn; Dr. B. S. Kline; Mr. L. Mazzini; the Medical Center, Public Health Service, Hot Springs National Park, Ark.; and the Venereal Disease Research Laboratory, Public Health Service, Chamblee, Ga., participated in this investigation.

Dr. Olansky is director of the Venereal Disease Research Laboratory, Venereal Disease Division, Public Health Service, Chamblee, Ga.; Mr. Harris, assistant director, is in charge of the serology section; Miss Vinson, Mr. Bossak, and Mr. Portnoy are bacteriologists in the serology section—Miss Vinson in the research unit; Mr. Bossak, assistant chief; and Mr. Portnoy, head of the testing unit.

Method

Blood specimens were collected from 360 donors and distributed to the five participating laboratories during the period of the study. This was accomplished by collecting blood from 20 donors (17 to 18 syphilitic patients and 2 or more presumably nonsyphilitic individuals) at the medical centers in Hot Springs, Ark., and Alto, Ga., on Monday of each week and mailing

the specimens to the laboratories. Testing was performed on Thursday of each week in all laboratories so that approximately 72 hours elapsed between collection and testing, even in those instances when the specimens reached the laboratory earlier.

Six vacutainers (10 ml.) of blood were collected from each donor. Blood was immediately removed from the last vacutainer and used to prepare 10 slides, each containing 2 drops (0.05 ml.) of blood, for the Chediak tests, and two capillary tubes for the micro-VDRL slide test. One vacutainer of blood and two slides containing dried blood, from each patient, were sent to each participating laboratory on the day bloods were collected. Capillary tubes of blood were distributed only to the two Public Health Service laboratories.

Each of the five laboratories performed the Chediak test, a modification of the Chediak test using VDRL antigen, and any other modification of the Chediak technique that they might select on the specimens supplied as dried blood on the two glass slides. The tubes of blood supplied serum that was tested quantitatively by any standard method in use at the laboratory. The Medical Center, Hot Springs National Park, Ark., and the Venereal Disease Research Laboratory, Chamblee, Ga., each performed quantitative microtests on the capillary tube specimens, using the micromodification of the VDRL slide test (3).

Antigens for the Chediak test and for those tests employing VDRL antigen were distributed by the Venereal Disease Research Laboratory from common lots. Antigen for the Chediak test had been prepared and was supplied for this study by Dr. Chediak.

Before the survey started, at least one technical worker from each of the testing laboratories was sent to the Venereal Disease Research Laboratory for training in the Chediak and the Chediak-VDRL test techniques. Mr. Canefax visited the Venereal Disease Research Laboratory to demonstrate the micro-VDRL slide test.

The results of all tests were recorded on report forms provided for this purpose and returned to the Venereal Disease Research Laboratory for review and compilation. Final

tabulation and statistical analysis of these findings were made in Washington by the Division of Venereal Disease, Public Health Service.

CHEDIAK TEST

(As described and demonstrated by Dr. A. Chediak)

Reagents:

1. Chediak antigen.
2. 3.5-percent sodium chloride solution.
3. 1-percent sodium carbonate solution.

Equipment:

1. Chediak 3-piece slide holders.
2. ¼-inch steel bearings.
3. Electromagnet or forceps.
4. Microscope with 60× magnification.

Preparation of Antigen Emulsion:

1. Prepare alkaline saline solution by adding 0.12 ml. of 1-percent sodium carbonate solution to 10 ml. of 3.5-percent sodium chloride solution. Mix well.
2. In one tube (15 x 85 mm.) place 1 ml. of alkaline saline solution.
3. In second tube, place 0.1 ml. of Chediak antigen.
4. Heat both tubes in 56° C. water bath for 5 minutes.
5. Mix by pouring saline into the antigen, and back and forth three times.
6. Place tube containing emulsion in 56° C. water bath for 2 minutes.
7. Check emulsion by examining a drop at 50× to 60× magnification. Particles should be evenly dispersed with no clumping. This emulsion should be used within 5 minutes.

Technique:

1. Place slides on holder, fastening top to make a well around each specimen.
2. Add two ¼-inch ball bearings to each specimen.
3. Add 0.03 ml. of 3.5-percent sodium chloride solution to each specimen. This may be accomplished by delivering the salt solution from a 0.2-ml. pipette (graduated in 1/100 ml.) or by dropping from a syringe fitted with a 15-gauge needle held in a vertical position. The needle should be tested for delivery of 0.03 ml. of 3.5-percent sodium chloride solution on the day of use.
4. Shake slide holders with irregular motion for 1 minute or until dried blood is resuspended in saline.
5. Add 0.03 ml. of Chediak antigen emulsion with a 0.1- or 0.2-ml. pipette graduated in 0.01 ml.
6. Rotate at 180 rpm for 3 minutes.
7. Remove ball bearings with electromagnet or forceps.
8. Place cover on slide holder and let stand for 20 minutes.
9. Read, using microscope with 60× magnification. Tests should be read within 30 minutes but not prior to 20 minutes after rotation.
10. Report as follows:

Negative-----	No clumping.
Doubtful-----	Small clumps.
Positive-----	Moderate and large clumps.

CHEDIAK-VDRL TEST

Reagents:

1. VDRL flocculation antigen.
2. VDRL buffered saline solution.
3. 3.5-percent sodium chloride solution.

Equipment:

1. Chediak 3-piece slide holders.
2. ¼-inch steel ball bearings.
3. Electromagnet or forceps.

Preparation of Antigen Emulsion:

1. Prepare and check VDRL antigen emulsion as directed in the Manual of Serologic Tests for Syphilis (4).

2. Prepare a diluted VDRL antigen emulsion by adding one part of VDRL buffered saline solution to one part of VDRL antigen emulsion. The diluted emulsion should be allowed to stand 10 minutes before use and should be used within an hour.

Technique:

(Two dried-blood specimens from the same donor are tested simultaneously.)

1. Place slides on holder, fastening top to make a well around each specimen.

2. Add two ¼-inch ball bearings to each specimen.

3. Add 0.03 ml. of 3.5-percent sodium chloride solution to each specimen. This may be accomplished by delivering the salt solution from a 0.2-ml. pipette (graduated in 1/100 ml.) or by dropping the solution from a syringe fitted with a 15-gauge needle held in a vertical position. On the day of use, the needle should be tested for delivery of 0.03 ml. of 3.5-percent sodium chloride solution.

4. Shake slide holders with irregular motion for 1 minute or until dried blood is resuspended in saline.

5. To one specimen, add 0.03 ml. of VDRL antigen emulsion. To the second specimen, add 0.03 ml. of diluted VDRL antigen emulsion. Emulsions are added with a 0.2-ml. pipette graduated in 0.01 ml.

6. Rotate at 180 rpm for 3 minutes.

7. Remove ball bearings with electromagnet or forceps.

8. Read tests immediately, using microscope with 60× magnification.

9. Report as follows:

Reactive (R)----- Definite clumping of antigen particles.

Nonreactive (N)-- No clumping of antigen particles, or very slight roughness.

NOTE: A test report is the composite of results obtained with diluted and undiluted antigen emulsions. When either result is reactive (although the other may be nonreactive), the report shall be "reactive." When both results are nonreactive, report shall be "non-reactive."

CHEDIAK-KLINE TEST

Reagents:

1. Standard Kline antigen emulsion (cardiolipin-lecithin antigen). Prepare antigen emulsion as di-

rected in Manual of Serologic Tests for Syphilis (4a).

2. 2.0-percent sodium chloride solution.

Equipment:

1. Chediak 3-piece slide holders.
2. ¼-inch steel ball bearings.
3. Electromagnet or forceps.

Technique:

1. Place slides on holder, fastening top to make a well around each specimen.

2. Add two ¼-inch ball bearings to each specimen.

3. Add 0.06 cc. of 2.0-percent sodium chloride solution to each specimen. This may be accomplished by delivering the salt solution from a 0.2-cc. pipette (graduated in 1/100 cc.) or by dropping two drops from a syringe fitted with a 15-gauge needle held in a vertical position. The needle should be tested for delivery of 0.03 cc. of 2-percent sodium chloride solution on the day of use.

4. Shake slide holders with irregular motion for 1 minute or until dried blood is resuspended in the salt solution.

5. Remove ball bearings with electromagnet or forceps.

6. To each specimen add 1 drop of standard Kline antigen emulsion (0.008 cc.).

7. Rotate at 180 rpm for 4 minutes.

8. Read tests immediately using a microscope with 100× magnification.

9. Report results as with the standard Kline test (Manual of Serologic Tests for Syphilis (4b)).

CHEDIAK-MAZZINI TEST

Reagents:

1. Mazzini-cardiolipin antigen (7).
2. Mazzini buffered saline solution.
3. 0.9-percent sodium chloride solution.

Equipment:

1. Chediak 3-piece slide holders.
2. ¼-inch steel ball bearings.
3. Electromagnet or forceps.

Preparation of Antigen Emulsion (5):

1. Pipette 0.4 ml. of the buffered saline solution to the bottom of a 30-ml. round bottle.

2. With a 1-ml. pipette, measure 0.4 ml. of the cholesterolized antigen (measurement is made from the tip of the pipette). Hold the bottle in the left hand and, imparting a rapid and constant rotating motion to the bottle, add the antigen directly and at once, blowing out whatever antigen is left in the pipette. Draw the emulsion into and out of the pipette exactly six times, returning all the emulsion left in the pipette on the last mixture.

3. Add 2.6 ml. of the buffered saline solution. Cork the bottle with a paraffin-coated cork and shake from bottom of the bottle to cork and back 50 times in 15 seconds.

Technique:

1. Place slides on holder, fastening top to make a well around each specimen.

2. Add two ¼-inch ball bearings to each specimen.

3. Add 0.03 ml. of 3.5-percent sodium chloride solution to each specimen. This may be accomplished by delivering the salt solution from a 0.2-ml. pipette (graduated in 1/100 ml.) or by dropping the solution from a syringe fitted with a 15-gauge needle held in a vertical position. On the day of use, the needle should be tested for delivery of 0.03 ml. of 3.5-percent sodium chloride solution.

4. Shake slide holders with irregular motion for 1 minute or until dried blood is resuspended in saline.

5. Add Mazzini cardiolipin antigen emulsion from observation tube fitted with 25-gauge needle held at approximately a 45° angle.

6. Rotate at 180 rpm for 4 minutes.

7. Remove ball bearings.

8. Add one drop of 0.9-percent sodium chloride solution from a medicine dropper.

9. Rotorate at approximately 100 rpm for 4 minutes.

10. Read tests immediately.

11. Report as:

Negative----- No clumping.

Weakly positive---- Slight to moderate clumping.

Positive ----- Definite clumping.

CHEDIK-KAHN TEST

Reagents:

1. Kahn standard antigen (lot 140B).

2. 0.9-percent sodium chloride solution.

Equipment:

1. Chediak 3-piece slide holders.

2. ¼-inch steel ball bearings.

3. Electromagnet or forceps.

Preparation of Antigen Suspension:

1. Same as for standard Kahn test. Prepare antigen emulsion as directed in Manual of Serologic Tests for Syphilis (4c).

Technique:

1. Place slides on holder, fastening top to make a well around each specimen.

2. Add two ¼-inch ball bearings to each specimen.

3. Add 0.05 ml. of 3.5-percent sodium chloride solution to each specimen. This may be accomplished by delivering the salt solution from a 0.2-ml. pipette (graduated in 1/100 ml.).

4. Shake slide holders with irregular motion for 1 minute or until dried blood is resuspended in saline.

5. Add 0.008 ml. of Kahn antigen suspension with a 0.1-ml. pipette graduated in 0.001.

6. Rotate at 180 rpm for 3 minutes.

7. Remove ball bearings with electromagnet or forceps.

8. Read tests immediately, using microscope with 60× magnification.

9. Report as follows:

Negative----- No clumping.

Doubtful----- Small clumps.

Positive----- Moderate and large clumps.

MICRO-VDRL SLIDE TEST (CANNEFAX)

This test is described in detail in "A Micromodification of the VDRL Slide Test," by Cannefax, Beyer, and Johnwick, on page 576 of this issue of *Public Health Reports*.

Results

Only qualitative test results obtained in the five laboratories with each test procedure are recorded in tables 1-5 since quantitative results are not obtained by any of the Chediak procedures. Qualitative test findings offer a basis for comparison of testing efficiency if only the ability of a test to react in a weakly or strongly positive manner with specimens from syphilitic donors is considered. This ability to "detect" serologically positive blood specimens is important if the tests requiring only small-volume

Table 1. Results obtained on whole blood and on dried blood specimens tested in the Venereal Disease Research Laboratory, Chamblee, Ga.

Tests	307 syphilitic donors					45 presumably nonsyphilitic donors

blood collection, such as the Chediak test, are used for screening child or baby groups for congenital or acquired infections.

The results of tests on specimens from eight of the presumably nonsyphilitic blood donors used in this study were omitted from final tabulation because other than negative reactions were obtained on the whole-blood sample tested by one or more author serologists, and adequate information regarding the clinical status of these individuals could not be obtained. Only the author's test, as performed in his laboratory, was considered in this regard. Positive or weakly positive (doubtful) reactions were produced by five of these specimens in the Mazzini

test, six in the VDRL slide test, three in the Kline test, and two in the Kahn test.

Results of the Chediak and Chediak-VDRL tests, as reported by the five laboratories, are compared with the quantitative VDRL slide test findings in tables 6 and 7. These tables present the zones of relative agreement between the tests on dried blood specimens and the VDRL slide test in terms of quantitation. The VDRL slide test results used in these tables were those reported by the Venereal Disease Research Laboratory.

Reports of the Chediak and Chediak-VDRL test results from the five laboratories on dried blood specimens from 45 presumably nonsyph-

ilitic donors are listed in table 8. Specific disagreements are noted in the footnotes to this table.

Discussion

The Chediak test as performed in the Venereal Disease Research Laboratory (table 1) was appreciably less sensitive than the other tests for syphilis, producing positive or doubtful reactions in approximately two-thirds of the specimens from syphilitic donors that gave those reactions in the other tests. The rela-

tive percentage reactivity of the Chediak test on specimens from syphilitic donors was not the same in each laboratory. The percentages ranged from 60.8 percent (Kline laboratory, table 4) to 77.9 percent (Kahn laboratory, table 3) as compared with the standard flocculation test results on serum which ranged between 91.5 percent (VDRL slide test, table 2) and 98.7 percent (Mazzini-cardiolipin test, table 5) and the Kolmer complement-fixation test result of 87.5 percent (table 2). These findings indicate that the Chediak test detected 70 to 80 percent of the syphilitic donors in this study whose

blood gave positive or doubtful reactions in standard tests for syphilis using serum.

The modified Chediak test using VDRL test antigen, and referred to as the Chediak-VDRL test, was the only modification of the Chediak test performed by all five participating laboratories. This technique called for reporting results as "reactive" and "nonreactive" so that all reactions equivalent to positive and doubtful or weakly positive are included under

the "reactive" heading. In each laboratory, this test was more reactive on specimens from syphilitic donors than was the Chediak test. The Chediak-VDRL test showed reactivity percentages of 86.6, 88.6, 92.4, 84.3, and 90.5, respectively, and a reactivity percentage of 88.5 percent for all laboratories. These figures show a closer relationship with test results obtained by serum tests since approximately 90 percent of the reactors in the specimens from

⁷ All laboratories except Kline, 1.

the syphilitic donor group, with all tests, were detected by this method. Inspection of the reactivity percentage figures for each test (tables 1-5) shows that an even closer agreement exists between the Chediak-VDRL test and the selected single testing procedures.

The third group of tests performed on dried blood samples included the Chediak-Kahn, Chediak-Kline, and Chediak-Mazzini tests using the respective antigens designated by the latter names. These tests showed reactivity ratings of 88.6 percent, 88.8 percent, and 88.4 percent, respectively, so the ability of these tests to produce positive or doubtful reactions on the specimens from syphilitic donors appears to be about the same as the Chediak-VDRL test.

The relative specificity of these tests on dried blood is not so clear from the reported findings. The number of positive plus doubtful reactions obtained by the Chediak method on the dried blood samples from presumably nonsyphilitic donors as recorded in tables 1-5 are 12, 7, 19, 7,

12, with an average of 11.4, yielding an over-all specificity rating of approximately 75 percent. However, it is noted that the largest number of these reactions were obtained in one laboratory (table 3) that also reported only 14 negative reactions on this group of specimens from presumably nonsyphilitic donors using the Chediak-Kahn and Chediak-VDRL procedures. This may indicate that the dried blood samples tested by this laboratory were either not similar, at the time of testing, to those tested in the other laboratories or that technical difficulties prevented the obtaining of clearly negative reactions at this testing station.

The Chediak-VDRL modification, as performed in the five laboratories, failed to give negative findings in 3, 4, 29, 0, and 7 instances, respectively, in the "negative" (presumably nonsyphilitic) donor group as recorded in tables 1-5. The lack of agreement between laboratories is greatest in this group of reports, so an average of findings under these circumstances probably would have little significance. The major disagreement in this regard was also from a single laboratory (table 3).

The results recorded in tables 1, 2, 4, and 5 show, in each instance, that the modifications of the Chediak test (Chediak-VDRL, Chediak-Kline, Chediak-Mazzini) had better sensitivity and specificity ratings than the original Chediak test performed at the same time in the four laboratories. These four tests employed cardiolipin-lecithin antigens. In the fifth instance (table 3), the two modified Chediak tests (Chediak-Kahn and Chediak-VDRL) were more reactive than the original Chediak test. However, all three of these tests had very poor specificity ratings. Findings reported by all five laboratories indicate that the Chediak test, modified to use cardiolipin-lecithin antigens, may be operated at a more efficient level than the original Chediak test as a "detector test" for syphilis. Evidence acquired during this study shows no definite preference for any one of the cardiolipin antigens used (Kline, Mazzini, VDRL).

Comparative reproducibility of the Chediak and Chediak-VDRL tests as portrayed in tables 6 and 7 favors the latter test. Complete agreement between results obtained in all five laboratories is more than twice as great with the Chediak-VDRL test (74 percent as opposed to

32 percent) and approximately 90-percent agreement was obtained by four of the five laboratories using this test. This indicates that a favorable percentage of agreement may be expected from laboratories performing the Chediak-VDRL test without lengthy technician training periods. However, these findings also may reflect less variability in antigen emulsions used from time to time in the several laboratories rather than a direct human variable such as ability to conduct tests or read results. The VDRL antigen emulsion is more stable and may be used for a longer time after being prepared than the Chediak antigen emulsion.

The micro-VDRL slide test results reported by two laboratories (tables 1 and 2) were in close agreement as to reactivity on specimens from syphilitic donors showing that 92.6 percent and 92.5 percent, respectively, of the specimens tested gave positive or weakly positive findings. However, 9 of 42 specimens from the nonsyphilitic donor group were reported by the Venereal Disease Research Laboratory as positive or weakly positive with the micro-VDRL test and only one positive reaction was reported by the Medical Center laboratory on 45 specimens from the same group.

It was also noted that 27 (8 percent) of the 352 specimens (307 from syphilitic donors, and 45 from presumably nonsyphilitic donors) submitted in capillary tubes for the micro-VDRL test were not tested at the Venereal Disease Research Laboratory while reports of microtest results were issued on all 352 such specimens by the Medical Center laboratory. The 27 specimens listed under the "not tested" heading for the micro-VDRL test by the Venereal Disease Research Laboratory were untestable due to loss of serum either in transit or in the centrifuge, or due to breakage of the capillary tube in the centrifuge. These factors are not evident in the reports of this test by the Medical Center laboratory because serum from the vacutainer tubes was used for testing whenever the capillary tube specimen was lost through leakage or breakage. The number of these losses that occurred is not recorded.

The relative efficiency of a testing procedure is based not only on test specificity and sensitivity but also on the effectiveness with which an

adequate specimen can be obtained and delivered to the laboratory. Loss of serum by breakage or leakage of tube in transit or through normal handling in the laboratory weighs against the micro-VDRL slide test procedure if the experience of the Venereal Disease Research Laboratory in this study indicates the average expectancy for adequate specimens to be received in the laboratory. A loss of 8 percent of the specimens submitted reduces collection rates to at least 92 percent, if an adequate specimen could be obtained from every donor. However, since the capillary tube is essentially similar to the large blood tubes, it is probable that deterioration of the blood sample in the capillary tube would not be more rapid than if collected in a larger tube.

The micro-VDRL slide test provides for quantitation if an adequate blood sample is collected. This would require approximately 0.15 ml. of blood, an advantage over the tests on dried blood specimens that do not provide for quantitation.

Findings reported in this study indicate that the Chediak test modifications using cardiolipin-antigens and the micro-VDRL slide test would be approximately equally effective as "detector tests" for syphilis. The modified Chediak tests detected approximately 90 percent of the specimens that gave positive reactions in other tests when performed on 72-hour-old blood samples. Previous studies have shown that dried blood samples are more reactive when stored for shorter periods of time. The 8-percent loss of capillary blood specimens for the micro-VDRL slide test placed this test in a comparable position with the Chediak modifications.

A field study of these two types of collection and testing procedures would be needed to determine the method of choice. Several factors that may influence this selection are (a) type of donor group, whether adult, child, or infant, (b) time interval between blood collection and testing, and (c) capability of the laboratory to perform either test efficiently.

Summary

1. Results obtained in five laboratories with the Chediak test and its modifications on dried

blood specimens plus several other tests on heated serum are presented.

2. The relative reproducibility of the Chediak and Chediak-VDRL tests among the five participating laboratories is shown in tabular form and is discussed.

3. Relative efficiency of the tests on dried blood specimens, as compared to tests on heated serum as "detector" tests for syphilis is discussed.

4. The micro-VDRL slide test findings, as reported by two laboratories, are presented and compared with results of other testing procedures.

The Chediak Test— A Preliminary Report

By AD HARRIS
SIDNEY OLANSKY, M.D.
HULDA VINSON, B.S.

The development of a test for syphilis requiring only a small amount of blood that could be collected with a minimum of equipment and difficulty by relatively untrained personnel has been the object of several investigative studies (1-9). Such a test would aid considerably in the detection of cases of syphilis from

which collection of the amounts of blood necessary for the standard testing procedures, using serum, is difficult or impractical due to lack of either adequate facilities or adequately trained workers.

In 1932 Dr. Alejandro Chediak of Havana, Cuba, published a technique for the serodiagnosis of syphilis requiring the collection of only a single drop of blood. The Venereal Disease Research Laboratory has recently studied this method as it was demonstrated by Dr. Chediak and explained in a personal communication from him. The purpose of this presentation is to report results obtained with the Chediak test and modifications of this technique using cardiolipin-lecithin antigens, under specified conditions.

CHEDIAK TEST

The mechanics of the Chediak test were retained with only minor changes throughout this study, using equipment and antigen supplied by Dr. Chediak. A brief summary of this method as demonstrated by Dr. Chediak during a visit to the Venereal Disease Research Laboratory, follows:

1. A drop of dried, "homogenized" blood, collected on a glass slide, is resuspended in 0.03 ml. of 3.5-percent sodium chloride solution. This is accomplished by placing the slide in a slide holder that forms a well above the blood sample so that two $\frac{1}{4}$ -inch steel balls may be put into each blood-saline mixture. The blood is then dissolved or resuspended by rotating the slide holder for approximately 1 minute.

2. After 0.03 ml. of antigen emulsion is added to each specimen, the specimens are rerotated on a flat-bed rotator for 3 minutes at 180 rpm.

3. Steel balls are removed, glass covers are placed into slide holders to prevent drying, and specimens are allowed to stand 20 to 30 minutes before being examined.

4. Slide holder covers are removed and specimens are read with a microscope at 60X magnification. Small clumps of antigen particles are interpreted as a doubtful reaction, large clumps indicate a positive reaction, and no clumping of antigen particles is read as a negative reaction.

Mr. Harris is assistant director of the Venereal Disease Research Laboratory, Venereal Disease Division, Public Health Service, Chamblee, Ga., and is in charge of the serology section; Miss Vinson is a bacteriologist in the research unit of the serology section; Dr. Olansky is director of the Laboratory.

The original Chediak antigen used in this test is a cholesterolized alcoholic extract of beef heart to which Tolu and Peru balsams have been added.

MODIFIED CHEDIAK TECHNIQUE (CHEDIAK-VDRL TEST)

I. Reagents:

1. VDRL flocculation antigen (10).
2. VDRL buffered saline solution (10).
3. 3.5-percent sodium chloride solution (prepared by dissolving 3.5 gm. dry sodium chloride in 100 ml. freshly distilled water).

II. Equipment:

- *1. Chediak 3-piece holders.
- *2. ¼-inch steel ball bearings.
- *3. Electromagnet or forceps.

III. Preparation of Antigen Emulsion:

1. Prepare and check VDRL antigen emulsion as directed on page 110 of the Manual of Serologic Tests for Syphilis, Supplement 22 to the Journal of Venereal Disease Information.
2. Prepare a diluted VDRL antigen emulsion by adding 1 part of VDRL buffered saline solution to 1 part of VDRL antigen emulsion. This diluted emulsion should be allowed to stand 10 minutes before use and should be used within 1 hour.

IV. Technique:

- *1. Place slides on holder, fastening top to make a well around each specimen.
- *2. Add two ¼-inch ball bearings to each specimen.
- *3. Add 0.03 ml. of 3.5-percent sodium chloride solution to each specimen. This may be accomplished by delivering the solution from a 0.2-ml. pipette (graduated in 0.01 ml.) or by dropping from a syringe fitted with a 15-gauge needle held in a vertical position. The needle should be tested for delivery of 0.03 ml. of 3.5-percent sodium chloride solution on the day of use.
- *4. Shake slide holders with an irregular motion for 1 minute or until dried blood is resuspended.
5. Add to each specimen 0.03 ml. of diluted VDRL antigen emulsion from a 0.2-ml. pipette graduated in 0.01 ml.
- *6. Rotate at 180 rpm for 3 minutes.
- *7. Remove ball bearings with electromagnet or forceps.
8. Read tests immediately, using microscope with 60× magnification.
9. Report as follows:

Reactive-----	Definite clumping of antigen particles.
Nonreactive-----	No clumping of antigen particles.

NOTE: All items marked with an asterisk are identical with those in the Chediak test.

Collection of Blood Specimens

Dried blood specimens were collected on 3- x 1-inch glass slides with frosted ends. An identifying number was written in pencil on the frosted portion of the slide. In this way the blood sample and identification were never separated from time of collection until testing was completed.

Slides were ringed on the reverse side with a wax pencil so that the dried blood specimen would coincide with the well formed when the slide was placed in the plastic slide holder. A drop of blood, obtained by puncturing a finger, toe, or heel with an automatic spring-type lancet, was allowed to fall onto the ringed portion of a properly labeled slide. The blood was then "homogenized" by stirring with an applicator stick for ½ to 1 minute.

Multiple slides of dried blood specimens and venipuncture blood samples for serum tests were collected simultaneously for comparative testing.

Procedure

In the first series of specimens tested with a cardiolipin-lecithin antigen an attempt was made to keep the reagin-antigen-particle ratio approximately the same as in the VDRL slide test. Since the dried blood was resuspended in 0.03 ml. saline (approximately one-half the 0.05 ml. serum of the standard test) the dose of antigen was reduced to a drop equivalent to ¼₁₂₀ ml. Rapid drying of these preparations during the rotation period rendered them unsatisfactory. To increase the amount of fluid and maintain the same reagin-antigen-particle ratio, the VDRL antigen emulsion was diluted in the proportion of 1 part of antigen emulsion to 3 parts of VDRL buffered saline solution and the dose of this diluted emulsion was set at 0.03 ml. With this combination, results approximately equal in sensitivity to those produced by Chediak antigen were obtained.

A second series of tests using 0.03 ml. of antigen emulsion, containing equal parts of VDRL antigen emulsion and buffered saline solution, gave fewer negative reactions in specimens from syphilitic donors than did other antigen-saline combinations tested. For this reason, this type of antigen emulsion was selected for the Chediak-VDRL test. Another advantage of the diluted VDRL antigen over the Chediak antigen, in the Chediak test, is that reactions were more rapid so that, when the VDRL antigen was used, the 20-minute waiting period of the Chediak test could be discarded, and reactions

could be read immediately after the 3-minute rotation period.

Attempts to further increase sensitivity by increasing the concentration of the sodium chloride solution used for resuspension of the dried blood resulted in crystallization of sodium chloride, which interfered with readings. Prolongation of the rotation time increased sensitivity but also produced very rough negative and weakly positive reactions on known negative donors. Several cardiolipin-lecithin antigens other than the one for the VDRL slide test were employed in varying dilutions without obtaining an increase in test sensitivity.

In order to determine the effect of storage on dried blood samples, multiple specimens were collected from unselected patients undergoing treatment for syphilis. These specimens were stored at room temperature for varying periods of time before being tested. Results obtained with the Chediak and Chediak-VDRL tests on dried blood specimens stored for 24 and 72 hours are listed in table 1.

Duplicate dried blood specimens and whole-blood specimens in vacutainers were simultaneously collected from a selected group of patients. These specimens were used to determine the relative capacities of the two tests on

dried blood to detect those donors whose serum produced positive or weakly positive reactions in the VDRL slide test. Results obtained in this comparison are recorded in table 2.

Effect of Storage on Dried Blood Specimens

Several dried blood samples were collected from each of a group of patients under treatment for syphilis in order to determine the effect of storage on this type of blood sample. These specimens were tested after storage at room temperature for 24 hours, 72 hours, and longer periods.

Some deterioration in reactivity was noted at all storage periods greater than 24 hours, and the longer storage periods produced the greatest loss in reactivity. However, since 72 hours was the shortest time that could be used for interlaboratory studies involving shipment of specimens to distant parts of this country and since this period would also be considered maximum for studies conducted by a single laboratory with state-wide blood collections submitted by mail, attention was specifically directed to the effect of this much delay between collection and testing on dried blood specimens.

Results presented in table 1 show that fewer "negative" reactions were obtained by both techniques at the earlier testing period and that a greater loss of reactivity was noted in Chediak test results on specimens stored for 72 hours than in the findings of the Chediak-VDRL test. The number of specimens used in this series is too small to indicate definite sensitivity positions of the tests used but they do serve as an indicator of relative test behaviors.

Storage conditions were not unusually humid during this study. To ascertain the effects of humidity on the dried blood samples during a storage period, several collections were placed in a glass jar over water, at room temperature. Under these conditions the blood specimens stored for 24 or more hours were unsatisfactory for testing due to presence of gross debris that did not redissolve in the saline.

Comparison of Results With Two Techniques

A series of specimens from 196 donors was tested, using the Chediak and Chediak-VDRL

Table 1. Effect of storage at room temperature on reactivity of dried blood specimens from 67 donors

Reactivity after 72 hours' storage	Reactivity after 24 hours' storage

techniques. Blood specimens collected by venipuncture at the same time were tested, using the VDRL slide test. The results obtained are presented in table 2.

One blood specimen that gave a negative reaction in the VDRL slide test had a positive Kahn test (32 units) and a 1 plus reaction in the Kolmer test. This specimen was positive in the Chediak test and reactive in the Chediak-VDRL test. The nine specimens that gave negative reactions in the VDRL slide test were also negative with both the Kahn and Kolmer tests. The remainder of these serums that gave positive reactions in the VDRL slide test also gave doubtful or positive reactions in either or both the Kahn and Kolmer tests.

Although the Chediak test gave positive or doubtful reactions on a few specimens that were reported nonreactive by the Chediak-VDRL procedure, 88 negative reactions were reported by the Chediak method and only 47 nonreactive results were obtained with the Chediak-VDRL test. The greatest discrepancy, in this regard, was found in the specimens of higher titer.

The highest percentage failure of the Chediak-VDRL to detect specimens that reacted in the VDRL slide test existed in those having 4 dils or less reactivity. In this zone, 39 of 65 VDRL slide test reactors were detected and in the group having more than 4 dils reactivity 109 of 121 reactors were found to be reactive by the Chediak-VDRL method.

Discussion

The Chediak and Chediak-VDRL tests were both found to be less sensitive or reactive than the VDRL slide test on a selected group of donors. Results obtained with dried blood specimens stored for varying periods of time before being tested indicate that loss of reactivity will accompany delay in testing this type of blood specimen. These two factors militate against the use of these tests on dried blood in preference to the more reactive tests for syphilis performed on heated serum.

The principal recommendations for tests for syphilis performed on dried blood are: (a) 100-percent collection of specimens may be expected even from infants since only one drop of blood is required; (b) blood may be collected by puncture of finger, toe, or heel with a minimum of apparatus; and (c) collection may be made by relatively untrained personnel. The tests must, however, be performed with standardized reagents by adequately trained laboratory personnel.

The balance of these factors favors the tests for syphilis that are performed on serum rather than on whole blood if the detection of syphilis is of paramount interest. The Chediak-type tests will, however, have a definite place under circumstances that will not allow the collection of larger quantities of blood.

The findings presented in this article are not

Table 2. Relative reactivity of Chediak, Chediak-VDRL, and quantitative VDRL slide tests on specimens from 196 patients

Test	Quantitative VDRL slide test

comprehensive enough to delineate clearly the relative efficiencies of the tests examined and are presented only as a preliminary report. Further study of the Chediak tests will be the subject of a later report.

NOTE: Since this study was completed, further trials have indicated that the reactivity coverage of the Chediak-VDRL test may be expanded by using both a diluted and an undiluted antigen emulsion.

Summary

1. Results obtained with the Chediak and Chediak-VDRL tests on dried blood specimens stored for 24 and 72 hours at room temperature are presented.
2. The results of the Chediak, Chediak-VDRL, and quantitative VDRL slide tests on blood specimens from 196 donors are presented.
3. A modified Chediak test technique (Chediak-VDRL) is described.
4. Advantages and disadvantages of Chediak-type tests are discussed.

A Micromodification Of the VDRL Slide Test

By GEORGE R. CANNEFAX, B.S.

HAROLD R. BEYER

EDGAR B. JOHNWICK, M.D.

Except for the lack of an authoritative sensitivity and specificity evaluation, the micro-modification of the VDRL slide test apparently provides a relatively simple and satisfactory method of collecting and testing small amounts of blood from infants, young children, and adults who present a problem in the collection of blood by venipuncture.

The results of testing 1,388 simultaneously collected specimens by the regular and the micro-VDRL test techniques are presented in this report. A request has been made that this modification of the VDRL slide test be included in the next National Evaluation of Serodiagnostic Tests for Syphilis.

Materials

Melting point capillary tubes (Kimble Glass Co. item 34500): Outside diameter, 1.5 to 2.0 mm.; length, 100 mm.; open at both ends. One hundred pieces are supplied in a corked glass vial. Prior to use the tubes are washed with Orvis detergent, rinsed with tap water followed by distilled water, and dried in a hot-air sterilizer. These tubes are used for the collection of blood specimens.

Glass tubing (Kimble Glass Co. item 46470): Glass tubing with an outside diameter of 4 mm., purchased in 4-foot lengths, and cut into 105-mm. lengths. The ends should be fire-polished. These tubes, when fitted with a rubber cap on each end, serve as carrying or protecting containers for the collection tubes.

Rubber caps for closing both ends of the protection tube: Micro rubber policemen as used with A. B. Thomas item 8804 or any cap that will fit 4-mm. glass tubing.

Ungraduated micropipettes: Drawn from 4-mm. outside diameter glass tubing. The pipette should have a

Mr. Cannefax is laboratory director, Mr. Beyer, medical technician, and Dr. Johnwick, medical officer in charge, Public Health Service Medical Center, Hot Springs, Ark.

length of 80 mm. and an orifice approximately 0.5 mm. in diameter.

Wax ring maker: Similar to A. H. Thomas item 3619-A. The ring maker should be wrapped with thread to make a ring 8- to 10-mm. inside diameter when dipped in molten wax at a temperature of approximately 120° C.

Automatic micropipette (A. H. Thomas item 8212-E): The rubber bulb supplied with this instrument must be modified for use with 4-mm. glass tubing. A rubber plug, with a hole large enough to hold the glass micropipette securely, is fitted snugly into the rubber bulb of the automatic pipette.

Test tubes 50 by 6 mm.: For receiving serum.

Rubber bulb (A. H. Thomas item 8773-L): For transferring serum from collection tubes to 50- by 6-mm. test tubes.

Methods

Collection of Specimens

A finger or heel is punctured so that there is a free flow of capillary blood, more profuse than the bleeding produced by the usual puncture for blood count and hemoglobin estimations. A No. 11 Bard-Parker or similar knife blade run through a No. 3 cork stopper may be used. The point of the blade should protrude from the cork approximately one-fourth inch. The blade and stopper are inexpensive and provide a control on the depth of the incision. If the cork is quickly and firmly pressed against the skin, an adequate flow of blood will usually be obtained. The lateral surface of the finger or heel bleeds more freely than the midline palmar or plantar surface.

Although the tube is called a "capillary tube" it will not fill by capillary attraction if it is held perpendicularly. The blood is collected by holding the tube nearly horizontal to the incision. In that position the blood will flow rapidly into the tube. If the incision requires massaging to well up more blood, the end of the tube is temporarily closed, or the tube is held horizontally so that the column of blood does not move along the tube and result in an air space when more blood is collected. The presence of air spaces in the column of blood may result in insufficient serum for testing.

When the column of blood is within approximately 10 mm. of the upper end of the tube, one end is plugged by forcing it into a 1/4-inch pad of nonhardening modeling clay. The other end does not require a plug. The collection

Figure 1. Collecting a specimen of blood from an infant.

tube is placed in the protecting or carrying tube and the rubber caps applied. The protecting tube, securely wrapped with a serologic test request form or other identification, is placed in a suitable mailing container and forwarded to the laboratory.

Calibration of Automatic Micropipette

The automatic pipette is calibrated to hold 0.015 ml. of serum by adjusting the knurled locking nut so that this amount is drawn into a 0.1- or 0.2-ml. pipette not more than 80 mm. in length that is calibrated to the tip. If the pipette has a diameter greater than 4 mm., it must be heated and drawn so that a constricted area, about 80 mm. from the tip of the pipette, measures approximately 4 mm. The pipette is scored with a file in the center of the constricted area, broken at that point, and the end fire-polished. The automatic pipette should be checked with this pipette each day before use to determine if 0.015 ml. is drawn into the ungraduated pipettes used for measuring serum.

Preparation of Wax Rings

Wax rings with a diameter of 8 to 10 mm., preferably nearer 8 mm., may be made of paraffin or other wax mixtures in common use. A single ring maker, not commercially available at this time, similar to A. H. Thomas item 3619-A, may be used for making the rings. The ring maker may be shaped from a paper clip bent to a diameter of 10 mm. and closed with a drop of solder. When wrapped with thread and dipped in paraffin at a temperature

Figure 2. Making wax rings for the micro-VDRL test.

of 120° C., the paper-clip ring maker will produce rings with an internal diameter of approximately 8 mm.

Preparation of Specimen for Testing

When the blood is received in the laboratory, the request slip accompanying the specimen is numbered and the melting-point tube is placed in a 100- by 13-mm. test tube similarly numbered. Before centrifuging, the clot is freed from the side of the melting-point tube by means of a wire stylet such as those supplied with 19-gauge hypodermic needles, or by a similar small wire. The specimen is centrifuged in the numbered test tube for 15 minutes at about one-half the revolutions per minute used with venous specimens. Inactivation is accomplished by placing the melting-point tube in a numbered 100- by 13-mm. test tube which is filled with water at 56° C. This tube has a small amount of cotton in the bottom sufficient to raise the end of the melting-point tube above the lip of the water-filled test tube. The inactivation temperature is maintained by placing the water-filled test tube in a serologic water bath commonly used for inactivation. After inactivation the melting-point tube is placed in the numbered test tube that was used to hold the specimen during centrifugation.

A small rubber bulb similar to that used with tubes of smallpox vaccine is placed over the serum end of the melting-point tube and an ampule file is used to score the tube just above the level of the clot. The tube, held horizontally, is broken at that point and the serum is

forced by means of the rubber bulb into a 50- by 6-mm. test tube, which is numbered with a wax pencil and/or placed in a wooden block with numbered holes.

Qualitative Testing

Serum is measured into the center of a wax ring by means of the automatic pipette and the ungraduated glass micropipette. The slide on the actuating arm of the automatic pipette is placed in the lower position. (The arm is actuated and the slide moved up and down with the thumb.) The tip of the glass pipette is placed in the serum and the arm depressed to force out serum that may have entered the glass tip by capillary attraction, the arm released, and the serum drawn into the glass pipette. The serum is discharged from the pipette into the center of a wax ring by raising the slide and depressing the arm. VDRL slide test (1) antigen is dropped onto the serum by means of a 25-gauge hypodermic needle attached to a 2-ml. syringe. The needle and syringe must be held vertically and deliver approximately 180 drops per milliliter. The serum-antigen mixture is rotated, read, and reported as described in the VDRL slide test procedure.

Quantitative Testing

Using an automatic pipette, 0.015 ml. of 0.9-percent sodium chloride solution is placed in each of 10 wax rings. Serum is drawn into the glass pipette attached to the automatic pipette as in qualitative testing. The slide of the automatic pipette is raised to the upper position and the 0.015 ml. of serum expelled into the first ring. With the slide held in the upper position the arm is repeatedly depressed and released (at least three times) so that the serum and saline are drawn into and forced out of the glass pipette to insure thorough mixing. When the mixture is expelled the last time, the slide is allowed to fall into the lower position. The tip of the glass pipette is placed in the serum dilution; the arm is depressed to force out any fluid that may have been drawn into the tip by capillary attraction, and released. The serum dilution thus obtained in the glass pipette is transferred to the second ring containing saline, and mixing manipulation is repeated. VDRL slide test antigen is added to each serum dilu-

Figure 3. Placing 0.015 ml. of serum in wax rings.

tion as described for qualitative testing. The serum dilutions are rotated, read, and reported as described in the VDRL slide test procedure.

Results

Qualitative Testing

The results of qualitative testing, in which 1,388 specimens were tested with the regular and micro-VDRL procedures, are shown in table 1. In this series the micro procedure was 1.8 percent more positive than the regular VDRL test when positive results were considered. When positive and weakly positive results were combined the micro procedure was 1.7 percent more positive. These differences in sensitivity are not statistically significant.

Table 2 is a presentation of comparative results of the two tests with respect to agreement or disagreement. The number of specimens found to be positive by both the VDRL slide and micro-VDRL slide tests is 641. Similarly, 510 specimens are identified by both tests as being negative. The total agreement between the two tests on the same specimens is 84.08

percent. However, if only two classifications of test results are used (positive-weakly positive and negative-rough negative) the total agreement of the two tests is 91.28 percent.

Quantitative Testing

Results of quantitative testing with 238 specimens are shown in table 3. It will be seen that 217, or 91.2 percent, of the entire series did not vary by more than one dilution between the regular and micro-VDRL slide tests. These variations and those of greater magnitude probably are due to technical errors. It is assumed that variations of this type will decrease as technical skill with small quantities increases.

Field Collection of Specimens

Field collectors were supplied with materials for collection of blood and were advised to procure specimens for the micro test in all instances in which venipuncture had failed or did not appear feasible. These workers received a demonstration of the collecting technique but were otherwise inexperienced in this type of specimen collection. Specimens of blood for the micro test were collected by the Arkansas State Board of Health in 1,451 cases in which venipuncture was not feasible, and the specimens forwarded to the Medical Center for testing.

Of these specimens 1,334 (91.9 percent), were satisfactory for qualitative testing. One hundred and seventeen (8.1 percent) were unsatisfactory for testing because of (1) insufficient quantity (93, 6.4 percent), (2) hemolysis (15, 1 percent), and (3) broken collection tubes (9, 0.6 percent). The results of the 1,334 specimens that were tested with the micro-VDRL test are as follows: 154 (10.6 percent) specimens were found to be positive; 1,180 (81.3 percent) specimens, negative.

Table 1. Results of 1,388 qualitative tests. VDRL slide test and micro-VDRL slide test

Test procedure	Positive		Weakly positive		Rough negative		Negative	
	Number	Percent	Number	Percent	Number	Percent	Number	Percent

4	3	2	1	----- 96	1	2	3	4
2	2	2	32		89	15	0	0

¹ Expressed as an increase in terms of serial dilutions.

Approximately one-third of the specimens which had quantities insufficient for testing came from the group of patients under 3 years of age. Thirty-eight of the positive specimens did not have sufficient serum for quantitation, and 181 of the negative specimens would have lacked sufficient specimen material if quantitation had been required.

Age was reported on the request form for 1,115 of the patients from whom blood specimens were collected in the field. Of these 1,115 patients, 167 (15 percent) were less than 1 year old; 189 (17.0 percent) were between 1 and 3 years; 287 (25.7 percent) were between 3 and 10 years; and 472 (42.3 percent) were between 10 and 60 years of age.

Summary

The micromodification of the VDRL slide test permits qualitative and quantitative testing with a specimen of 0.1 to 0.15 ml. (2 to 3 drops) of capillary blood.

The qualitative and quantitative modifications of the VDRL slide test herein described

consist of the performance of that test with one-third amounts of serum, antigen, and surface area.

Specimen material is obtained by finger, toe, or heel puncture and collection in "capillary" glass tubes.

An automatic pipette, fitted with an inexpensive ungraduated glass pipette, is employed for serum measurement. Calibration of the automatic pipette and fabrication of the ungraduated glass pipettes are described.

It was found that 6.4 percent of all the specimens received were of insufficient quantity for qualitative testing. The collection of specimens in "capillary" glass tubes would be greatly facilitated if an automatic lancet with a thin blade 4 mm. wide set to protrude 2 mm. were available. Such a lancet has been fashioned from the conventional type, and its use at the medical center has resulted in 100-percent collection of sufficient specimen material.

Sensitivity and specificity ratings have not been determined for this modification of the VDRL slide test. However, since the series of tests reported here showed the micro procedure to yield 1.8 percent more positive results, it may be assumed, for the present, that the procedure may be a little more sensitive. It does not appear probable that this percentage increase in test sensitivity is sufficient to reduce the specificity of this modification below acceptable limits since the difference as shown with these data is not statistically significant.

Quantitative testing is accomplished by preparing serum dilutions within the wax rings of the slide in place of test tubes. Comparative quantitative testing of the micro technique and the regular VDRL slide test has shown 91.2 percent of the tests to vary by no more than one dilution. It is assumed that variations greater than one dilution have been due to faulty technique and that the incidence and magnitude of variations will decrease as experience with the test procedure increases.

Most of the patients from whom specimens were obtained in the field probably would not have had the benefit of a serologic test for syphilis if this new collecting technique had not been available to the field worker. As previously indicated, analysis of 1,115 patients for whom age was reported showed that 32 percent

of the patients were less than 3 years of age, 57.7 percent were under age 10, and 42.3 percent over age 10.

A Statistical Evaluation Of the FPM Test

By AD HARRIS
SIDNEY OLANSKY, M.D.
HENRY MILLER, B.S.

A further evaluation of the efficiency of the filter paper microscopic (FPM) test (1) as a "detector" test for syphilitic infection, based on specimens from 276 donors, including the specimens from the 266 donors analyzed in the preliminary report (2) is presented in this paper. As noted in that report, collection and distribution of blood specimens were carried out by the Eastern Medical Center, Durham, N. C., and by the staff of the Venereal Disease Research Laboratory at the Alto Medical Center, Alto, Ga.

Each Tuesday, blood specimens from 10 to 30 donors were collected and five filter paper strips and five tubes of whole blood were prepared from each specimen. One filter paper strip and one tube of whole blood from each donor were sent to each of the following laboratories: Dr. Kahn, Dr. Kline, Mr. Mazzini, the Eastern Medical Center, and the Venereal Disease Research Laboratory. On the following Friday each laboratory performed the FPM test on the filter paper in accordance with the test protocol and,

Mr. Harris is a serologist and the assistant director of the Venereal Disease Research Laboratory; Dr. Olansky is the director; Mr. Miller is a statistician in the Division of Venereal Disease, Public Health Service.

in addition, any modification of the FPM test that they might devise. The tube of whole blood was used to perform tests commonly used in the various laboratories, hereafter referred to as standard tests. Antigen used for the FPM and VDRL tests, if performed, was distributed by the Venereal Disease Research Laboratory.

At the time of collection and distribution of specimens, the Eastern Medical Center and the Alto Medical Center established a diagnosis by clinical and serologic findings of all donors from whom the specimens for this study were taken.

For purposes of evaluation, two methods of comparison of the FPM test are presented. The first method discussed is that of comparing the test results of each participating laboratory with established diagnostic results. The second method disregards diagnostic findings and compares the results of the FPM test findings in a particular laboratory with the other tests performed in that laboratory. The second method of evaluation has been used for the following reasons: (a) A diagnosis by clinical means is not always obtainable in actual practice; (b) an error in diagnosis is possible. Certain specimens collected from donors diagnosed as positive or doubtful have been found to be negative by the standard tests. The agreement by all tests in a laboratory as to the negativity of these particular (diagnosed positive) specimens ranges from 2 specimens in the Venereal Disease Research Laboratory to 18 specimens in the Kahn laboratory. This type of disagreement (diagnosed positive, tested negative) may be due to laboratory technique or to an error in diagnosis. In either case a comparison of tests within laboratories seems justifiable.

In both methods, comparison of specimens as to agreement or disagreement is made only when tests have been performed. Tests giving doubtful reactions are considered positive, since it is not the purpose of this study to analyze the quantitative results produced by the FPM test.

Method 1

The various diagnoses of syphilis, based on clinical and serologic findings, established by the Eastern and Alto Medical Centers have been classified as follows:

1. Positive—secondary; early latent; late latent; asymptomatic central nervous system (CNS); symptomatic CNS (paresis, tabes, etc); cardiovascular; CNS plus cardiovascular syphilis (CVS); congenital; serorelapse; infectious relapse.

2. Negative—normal; other venereal diseases, not syphilis.

Since clinical manifestations were not considered by the testing laboratories in determining results, and negative blood tests are highly probable in patients with primary syphilis, the following diagnoses of the centers were eliminated from comparison: (a) primary; (b) reinfection regardless of stage of syphilis; and (c) suspect only or late syphilis.

Table 1 shows the percent of agreement and disagreement of the serologic test results obtained in each of the five testing laboratories as compared with the diagnoses of the Alto and Eastern Medical Centers. Tables giving the serologic test results as compared with the diagnoses made in these laboratories may be obtained from the authors upon request.

Eight different tests were performed in the Kline laboratory, three of which were modifications of the FPM test. Of 231 specimens used for comparison between the FPM test and the diagnosis, 161 were found to be positive and 13 negative by both the FPM test and the diagnosis. The percent of agreement is 75.3 percent. Fifty-six specimens were considered positive by the diagnoses, negative by the FPM test. The rate of disagreement is 24.7 percent. The FPM test modifications agree rather closely with those of the FPM test. The highest agreement found between the FPM test or any of its modifications is 81.8 percent for the FPM modification test. The difference between this rate of agreement and the lowest rate of agreement between the diagnosis and a standard test (88.7 percent for the Kline diagnostic) is statistically significant at the 5-percent level. This difference may be attributed to the inability of the FPM test and its modifications to identify specimens diagnosed as positive.

In the Venereal Disease Research Laboratory, the FPM test agreed with the diagnosis on 168

Table 1. Percent agreement and disagreement of serologic test results of five laboratories with the established diagnostic results¹

¹ Based on clinical and serologic findings at Eastern and Alto Medical Centers.

NOTE.—More detailed data may be obtained from authors.

of the 231 specimens used for comparison, a rate of agreement of 72.7 percent. With the exception of one comparison, disagreement between FPM and diagnostic results was due to 62 specimens diagnosed positive but negative by the FPM test. The highest degree of agreement in this laboratory is 97.2 percent and is found under the results of the Kline standard test. Only 2.8 percent were found to be in disagreement. All differences in the rate of agreement between the FPM test and the standard tests are significant beyond the 5-percent level, again showing the difference in the ability of the FPM and the standard tests to recognize positive diagnosed specimens.

The results of tests in the Eastern Medical Center laboratory and the Kalin laboratory are in accord with results in the laboratories already discussed. However, special attention is called to the comparison of diagnostic results and results of tests performed in the Mazzini laboratory. The rate of agreement between diagnostic results and the FPM test and a modification, the FPM-Mazzini-cardiolipin test (2) using the Mazzini antigen instead of the VDRL antigen, is approximately 20 percent greater than any other FPM test or FPM test modifications found in the other participating laboratories. The percent of agreement in the FPM test as compared to the agreement in the VDRL slide and the Mazzini-cardiolipin tests is significantly different at the 5-percent level. However, there is no significant difference between the FPM-Mazzini-cardiolipin test and the VDRL slide and Mazzini-cardiolipin tests. This high degree of agreement between diagnostic results and the FPM and FPM-Mazzini-cardiolipin test results was also noted in the previous report (2). In answer to an inquiry by the authors of that article, Mr. Mazzini reported that the FPM test performed in his laboratory was being carried out in accordance with the testing procedure.

Under this first method of comparison, the laboratory results of the FPM test and the standard tests have shown a significant difference in agreement with the diagnoses. Although a few specimens diagnosed as negative are positive by the FPM test, the greatest difference may be attributed to the inability of the

FPM test to identify specimens from donors in positive diagnostic categories.

Method 2

Results of method 2 are presented in table 2. By this procedure the results of the FPM test are compared with respect to agreement or disagreement with the various tests performed within each laboratory. To determine what variation could be expected within a laboratory, two standard testing methods whose efficiency is generally known are compared and will be referred to as control groups. Data from these groups are presented in table 3.

In the Kline laboratory, the results of comparison of tests by this method show a high degree of agreement between the FPM test and its modifications. This may be due to the similarity of reactivity between these tests. The FPM-FPM standard comparison reveals almost perfect agreement—99.6 percent. However, the agreement between the FPM test and the standard tests in this laboratory is quite low. The greatest amount of agreement in these comparisons is 84.2 percent in the FPM-Kline diagnostic comparison. The lowest agreement (78.0 percent) exists in the FPM-Kline standard and the FPM-Kline exclusion comparisons, and is attributable in each case to 60 specimens diagnosed negative by the FPM test but positive by the two Kline tests.

The tests used as a control group for this laboratory (VDRL slide-Kline standard) show an evident similarity, with an agreement rate of 96.3 percent (table 3). While perfect agreement cannot be expected, this does indicate rather definitely that the low rate of agreement between the FPM-VDRL slide and the FPM-Kline standard tests is not due to the fact that the VDRL slide and Kline tests lack specificity, but rather that the FPM test is inefficient in the identification of positive serologic specimens.

In the Venereal Disease Research Laboratory, no modifications of the FPM test were performed but, as in the Kline laboratory, the rate of agreement between the FPM test and the standard tests is rather low, lower than one might expect if these tests are comparable. The greatest amount of disagreement occurs in the

¹ As performed in accordance with the test protocol.
NOTE. More detailed data may be obtained from authors.

FPM-Kline standard comparison, indicating that the agreement between the two tests was 72.6 percent; disagreement, 27.4 percent. Disagreement is due to 71 specimens indicated positive by the Kline test and negative by the FPM test. The control group (Kahn standard-Kline standard) indicates quite a difference in agreement in contrast to the FPM comparisons. Here the total agreement is 93.3 percent. Statistical tests carried out between the FPM-Kahn standard and the FPM-Kline standard comparisons showed no statistical difference. However, the difference between the Kahn standard-Kline standard comparison and the other two comparisons mentioned is highly significant, due to

the large number of positive specimens called negative by the FPM test.

At the Eastern Medical Center laboratory, the control group of Kahn standard and Kolmer simplified tests shows a total agreement of 95.2 percent, whereas the highest agreement between the FPM test and any standard test performed in this laboratory is only 79.8 percent (VDRL slide test). The FPM Dri-Rite test indicated 93.3-percent agreement with the FPM test. For further evidence of reactivity of a modification of the FPM test, the FPM Dri-Rite test and the Kahn test were compared and an agreement of 83.0 percent was found. This was not significantly different from the results

Table 3. Percent agreement and disagreement of control groups within laboratories

Laboratory	Control groups	Percent agreement	Percent disagreement
Kline	VDRL slide v. Kline standard	96.3	3.7
Venereal Disease Research Laboratory	Kahn standard v. Kline standard	93.3	6.7
Eastern Medical Center	Kahn standard v. Kolmer simplified	95.2	4.8
Mazzini	VDRL slide v. Mazzini-cardiolipin	99.3	.7
Kahn	Kahn standard v. Kahn presumptive	97.0	3.0

of comparisons of the FPM test with the other standard tests in this laboratory, indicating the similarity of the two FPM tests in their inability to agree with other tests in identifying positive specimens.

The results at the Mazzini laboratory show a higher percentage of agreement between the FPM test and standard tests than was obtained by any of the other laboratories. The agreement of FPM results with the diagnoses established by the medical centers was also much higher in this laboratory than in the other testing laboratories. However, the control group of VDRL slide-Mazzini-cardiolipin tests is also in high agreement (99.3 percent) which is significantly different (5-percent level) from the FPM-VDRL slide (93.3 percent) and the FPM-Mazzini-cardiolipin comparison (92.6 percent), again indicating the lack of reactivity in the FPM test (table 3).

The comparison of results from the Kahn laboratory shows somewhat higher agreements between standard tests (with the exception of the Mazzini laboratory) than those obtained in the other three laboratories. However, the conclusion reached from results obtained by all reporting laboratories appears to be the same—the failure of the FPM test to identify positive specimens. The degree of agreement between the control groups can be seen in table 3. These five groups of tests have an average agreement of 96.3 percent compared to 81.0 percent between the FPM and standard tests.

Since the FPM test is less reactive than the commonly employed laboratory tests, it would be less efficient as a "detector" test for field survey use. However, as stated in the previous report (2), this fact should not militate against the use of the FPM test under conditions in which another type of blood collection cannot be used.

Summary

1. Filter paper strips and tubes of whole blood from 276 donors were distributed to 5 laboratories.

2. Each laboratory performed the FPM test in accordance with the testing protocol and any modification of the FPM test if they so desired. The tube of whole blood was used to

perform other testing procedures employed in the laboratories.

3. Two methods of analysis are presented. Both methods show that a significant difference (5-percent level) exists between the ability of commonly employed laboratory tests and the FPM test to identify positive and doubtful serologic specimens.

Use of the FPM Test In a Control Program

By CHARLES R. FREEBLE, Jr., M.D.
BERTINA ORSBURN, B.S.

When the filter paper microscopic (FPM) test for syphilis was reported by Hogan and Busch (1), it appeared to present a simple method of collecting, shipping, and testing blood. This method seemed especially desirable in screening children for congenital syphilis, since it obviated the necessity for jugular punctures. In Ohio, the test has been studied from the standpoint of ease of use under field conditions and by comparison with the standard serologic tests currently being performed by the Ohio Department of Health.

Use in Mass Testing Programs

The FPM technique is suitable for use in mass testing programs. Although more time is required to obtain a specimen of blood for the

Dr. Freeble and Mrs. Orsburn are with the communicable disease division of the Ohio Department of Health.

FPM test than for venipuncture, the preliminary preparation time for the FPM test is much less. The supplies necessary to carry out a testing program with the FPM test are minimal, and the specimens are easily handled and transported. It is not difficult to train a person to obtain a specimen for the FPM test, although experience obtained under supervision is necessary to insure suitable specimens.

During a mass blood testing and chest X-ray program in a northeastern Ohio county having a low syphilis incidence, blood specimens for the FPM test were collected from 902 persons of all ages. Three tests were positive. Results of serologic tests on blood samples obtained from these three persons by venipuncture, together with the histories and findings on physical examination, indicated that they were suffering from previously undiscovered latent syphilis.

After completion of the mass survey, two local health department nurses obtained 187 specimens for the FPM test from children in households which they visited in the ordinary course of their duties. They were enthusiastic about the procedure as a suitable method of obtaining blood specimens in the home. They pointed out that it would eliminate numerous nursing visits and the problem of arranging for attendance at clinics, in addition to overcoming parents' reluctance to permit jugular punctures on infants and small children.

Usually, little or no objection is offered to obtaining a blood specimen by finger puncture. Parents volunteer for the test and urge their children to submit to it. As many persons volunteered for the FPM test as for the chest X-ray. Of the 902 persons tested, 86 (9.5 per cent) were under 10 years of age.

Figure 1. Collecting blood for the FPM test from a child in his home.

Comparison With Standard Tests

Following exploration of the suitability of the FPM test for field use, a comparison was made of results of this test and results of standard Kahn, Kline, and Kolmer tests performed as a daily routine at the Ohio Department of Health laboratory. Specimens of blood in 8-cc. amounts were obtained by venipuncture from 897 persons admitted to the Central Ohio Rapid Treatment Center. Filter paper strips were saturated by dipping them into the tubes of blood. They were then drained and allowed to dry and the FPM test was performed by the method of Hogan and Buseh (1). The tubes of blood were forwarded to the laboratory of the Ohio Department of Health for serologic testing.

A comparison of the results of the FPM test with each of the other tests is presented in table 1. Based on the figures in table 1, the percentages of agreement between the FPM and

Table 1. FPM test results compared to results of Kahn, Kline, and Kolmer tests on specimens from 897 patients at Central Ohio Rapid Treatment Center

FPM	Kahn		Kline		Kolmer	
	Positive and doubtful	Negative	Positive and doubtful	Negative	Positive and doubtful	Negative
Positive and doubtful.....	686	41	726	1	714	13
Negative.....	51	119	106	61	87	83

Table 2. Diagnostic classification of 110 individuals whose blood specimens were negative with the FPM test but positive with 2 or more of the standard tests

Diagnosis	Previously treated	Not previously treated	Total
Primary-secondary	1	2	3
Early latent	22	11	33
Late latent	25	6	31
Asymptomatic central nervous system	15	4	19
Tabes dorsalis	6	0	6
Paresis	2	0	2
Early congenital	0	1	1
Late congenital	5	3	8
No venereal disease	0	7	7
Total	76	34	110

Kahn, Kline, and Kolmer tests were 89.7, 88.1, and 88.9, respectively; disagreement, 10.3, 11.9, and 11.1. The percentage of agreement indicates the number of instances in which both the FPM test and the standard tests gave positive or doubtful results, plus the instances in which both gave negative results. "Disagreement" means the number of times varying results were obtained by the two tests. Most of the disagreement between the FPM and Kline tests and the FPM and Kolmer tests is due to the large number of specimens that were positive by the standard tests and negative by the FPM test. While this discrepancy is also noted in the FPM-Kahn tests comparison, it accounts for a much smaller part of the disagreement.

Table 3. Results of quantitative Kahn test on 51 specimens negative to the FPM test

Kahn units	Number of specimens negative to FPM test
1	20
2	11
3	11
4	4
10	1
20	
40	2
80	1
160	1
Total	51

Of the 897 specimens tested, 110 were negative to the FPM test and positive to two or more of the serologic tests. The diagnoses of these 110 individuals are presented in table 2. Of 34 patients with untreated syphilis in all stages, blood tests of 27 were negative to the FPM test, but positive to two or more of the other tests. Results in Kahn titers on 51 specimens negative to the FPM test but positive to the Kahn test are shown in table 3.

Figure 2. Collecting blood for FPM test in a clinic.

Discussion

The FPM test offers a simple method for the collection of blood specimens, and, under field conditions, the test has definite advantages: (a) greater willingness of individuals to submit to and to allow their children to submit to finger punctures; (b) ease of obtaining specimens by nurses and other personnel after a minimum of instruction; and (c) saving of clinic and nursing time, since the test can be made at home. Little time is saved in mass testing programs, but the avoidance of time lost in handling supplies and equipment for venipuncture more than compensates for the time required to obtain blood for the FPM test.

However, the obviously lower reactivity of the FPM test mitigates its usefulness as a screening test. FPM, Kline, Kahn, and Kolmer tests on a series of patients at the Central Ohio Rapid Treatment Center yielded many more negative reactions with the FPM test than with the standard serologic test (table 1). Tests on

110 serums were reported negative to the FPM test and positive to at least two of the other tests (table 2). In a screening procedure with the FPM test these seropositive persons probably would have been missed. Despite its advantages in collecting, the lower sensitivity of the FPM test makes it of questionable value in obtaining reliable evaluation tests on children. These observations on reactivity are consistent with the previously reported findings of Harris and Olansky (2).

Summary

1. Results of field use of the FPM test in a demonstration screening of 902 individuals in an Ohio county and in obtaining 187 specimens from children during routine public health nursing visits to homes are reported. The filter paper method of blood collection has definite advantages, as it is suited to mass as well as home use, and professional personnel can be quickly trained to get satisfactory specimens.

2. Comparative studies of the FPM and standard tests in routine use in Ohio performed on 897 patients at the Central Ohio Rapid Treatment Center are reported. The lower reactivity of the FPM test by comparison with the other tests negates the definite advantages of ease of specimen collection, and limits the use of the test to instances in which no other method of obtaining a specimen is possible. False security which might result from a negative report by the FPM test renders the advisability of the test's limited use doubtful.

Tularemia From a Wood Rat in New Mexico

By DEAN H. ECKE, M.S., and ROBERT HOLDENRIED, Ph.D.

Tissue from a wood rat (*Neotoma albigula*) found dead at Gran Quivira National Monument, N. Mex., April 12, 1951, was shown in the laboratory to be infected with *Pasteurella tularensis* (McCoy and Chapin). This is the first time that *N. albigula* has been found nat-

urally infected with tularemia. Tularemia in a Pacific Coast species (*Neotoma fuscipes*), however, has been previously reported (1).

The superintendent of the Gran Quivira National Monument had observed dead cottontails (*Sylvilagus auduboni*) in the area during the previous 8 months. At his request a survey was conducted to determine the cause of the epizootic. Field-collected material was obtained by the plague survey crew of the New Mexico Department of Public Health. The crew cooperated with the Public Health Service's Western Communicable Disease Laboratory, San Francisco, Calif., which conducted the laboratory tests. The findings of this survey are recorded in the table.

Mr. Ecke is with the Communicable Disease Center of the Public Health Service, assigned as assistant sanitarian to the Thomasville Field Station, Thomasville, Ga. Dr. Holdenried, scientist, is also with the Communicable Disease Center and is assigned to the Santa Fe Field Station, Santa Fe, N. Mex.

Mammal species	Number mammals	Ticks			Fleas			Number with positive tissue ²
		Number	Average number per animal ¹	Number positive pools ²	Number	Average number per animal ¹	Number positive pools ²	
<i>Sylvilagus auduboni</i>	17	101	6	2	100	6	0	2
<i>Neotoma albigula</i>	42	0	0	0	130	3	0	1
<i>Peromyscus truei</i>	19	0	0	0	29	2	0	0
<i>Peromyscus maniculatus</i>	20	0	0	0	11	1	0	0
<i>Dipodomys ordii</i>	27	5	1	0	2	0	0	0
<i>Dipodomys spectabilis</i>	5	0	0	0	7	1	0	0
<i>Reithrodontomys megalotis</i>	1	0	0	0	1	1	0	0
<i>Citellus variegatus</i>	1	0	0	0	6	6	0	0
Total.....	132	106	-----	2	286	-----	0	3

¹ Averages rounded out to nearest whole number.² Positive for *P. tularensis*.

Ticks were numerous on cottontails in the area but were found, in small numbers, on only one species of rodent (*Dipodomys ordii*). Two pools of ticks from cottontails contained tularemia organisms. Fleas were found on all of the mammals captured. None of the flea pools were found to be infected even though taken from cottontails shown to have infected tissue or to be carrying infected ticks.

These observations suggest that the epizootic was primarily limited to the cottontail population, with the wood rat involved secondarily. In this area of New Mexico, wood rats and cottontails are frequently found in close association, often sharing the same living quarters. As a result, it is likely that the opportunity occasionally arises for a limited exchange of ectoparasites, and that the wood rat became in-

fectured with tularemia from ticks which had previously fed on an infected rabbit. The long period over which dead cottontails were observed and the large number of live animals remaining at the time of the survey indicate that the epizootic was not of a fulminating, rapidly spreading nature.

It is concluded that tularemia in the wood rat was a chance infection and that wood rats in this locality are not important in the ecology of tularemia.

A Drop in the Bucket

16 mm., sound, color, 13 minutes, 1951.
Audience: General public.

Available: Loan—State and local health departments; regional offices, Federal Security Agency. Purchase—United World Films, Inc., 1445 Park Avenue, New York 29, N. Y.

"A Drop in the Bucket" was produced for the Division of Dental Public Health of the Public Health Service by Warner-Pathe News, Inc.

This film tells the story of how one community brought the benefits of fluoridated water to its children—how the dentists, the health officers, the mayor, the water works engineer, and citizens got together and fought for fluoridation before it was a widely recognized public health measure.

Based in part on the story of how the people of Newark, Del., added fluoride to their water supply, the film portrays the down-to-earth situations that exist in every community—the typical conflicts, the doubts about fluoridation, and the

evidence to support its use. The film answers many questions parents ask: What good does fluoridation do? How much does it cost? What is fluoride? What does it look like? How do you add it to water? The film shows that fluoride in a water supply is not dangerous—it does not stain teeth nor make bones brittle. It does not harden water nor color it. Neither does it give any taste to water.

New Film Catalogs

USPHS Motion Pictures, A Selected List, includes 42 films which the Public Health Service has either produced or assisted in producing and which are considered currently useful. Essential data, a brief description of the content of the film, and the manner in which it can be obtained are given for each listing. This catalog does not include films produced by the Communicable Disease Center which are contained in the CDC Catalog of Motion Pictures and Filmstrips for Professional and Subprofessional Audiences. (A limited number of these are available from the Communicable Disease Center, Atlanta, Ga.)

In addition to films of general interest, subject areas covered by USPHS Motion Pictures are: cancer, dental health, diabetes, mental health, occupational health, rheumatic heart disease, small-milk-plant operation, tuberculosis, venereal disease, water pollution, excess weight, first aid, and rodent control.

• • •

USPHS Motion Pictures, A Selected List. 1952. 13 pages. Milne-

graphed. Available without charge from Public Inquiries Branch, Public Health Service, Washington 25, D. C.

Motion Pictures on Child Life, compiled by the Children's Bureau, is a list of more than 450 16-mm. films available from all sources on various aspects of child life and development. Most of the films are for adults. A few are for children although they are not planned for classroom use. As in the case of the Public Health Service listings, essential data, a brief description of the content of the film, and the manner in which it may be obtained are given for each. No attempt has been made to evaluate the films.

The following areas of the health field are covered in this catalog: health services, personal health and posture, prevention and treatment of disease, dental hygiene, handicapped children, mental health, and nutrition.

Areas of child life and development covered by the remaining listings are: adolescence, child care, child development, children in foreign countries, community life, juvenile delinquency, maternity care, recreation and play, safety, sex education, and welfare services. Supplements to the catalog will be issued from time to time.

Health Manpower in the U. S.

Health manpower is a matter of increasing concern to the United States as a whole and for many States and communities. Forthcoming tabulations of the 1950 Census of Population will provide detailed information as to the actual current situation. Meantime, a summary of data now available may be useful. Such a summary is presented here and is based on counts and estimates prepared by the medical and health professional associations.

Physicians

The latest available information for 1950 estimates a total of 200,040 physicians (table). For 1949 the American Medical Directory listed the names of 201,277 physicians. Of these 9,700 were retired or were not practicing medicine, and 12,500 were associated with Federal agencies. The active non-Federal physicians included about 90,000 general practitioners, 55,000 specialists, 25,000 physicians in hospitals (mainly interns and residents), and almost 4,000 not in private practice.

In the South, the ratio of physicians to population continues to be low. In 1949, the number of active non-Federal physicians per 100,000 population was 91 for the southern States, in contrast to 110 in the North Central Region, 125 in the West, and 158 in the Northeast (New England and Middle Atlantic States). The rate for the United States was 121 active non-Federal physicians per 100,000 population.

The Division of Public Health Methods of the Office of the Surgeon General, Public Health Service, prepared this section.

Present status of health manpower

Field	Number of practitioners, 1950	Number of graduates, 1951	Number of students, 1950-51
Medicine.....	¹ 209,040	6,135	26,191
Dentistry.....	² 80,876	2,830	12,169
Nursing.....	³ 322,300	⁴ 25,790	102,509
Veterinary medicine.....	⁵ 15,305	755	3,226
Sanitary engineering.....	⁶ 5,000	403	-----

¹ American Medical Association estimate for Dec. 15, 1950. ² American Dental Directory, 1950. ³ Estimated. ⁴ 1950 data. ⁵ Includes 244 graduates from undergraduate sanitary engineering courses or options within civil engineering courses; 152 with master's degree based on major in sanitary engineering; and 7 with doctor's degree for similar major.

Figure 1.

The ratio of all physicians to population was lower in 1950 than at the beginning of the century (fig. 1). In 1900, there were 119,700 physicians in the United States—157 per 100,000 population. The rate declined until 1930, when there were 125 doctors for 100,000 population, then gradually increased to 123 by 1940 and to 138 by 1950.

For the year 1950-51, the total enrollment of students in the 72 medical schools and the 7 basic science schools which offer the first 2 years of the medical course was 26,191.

The total of 6,135 graduates in 1951 is the largest to date, except for the period of accelerated training during the war, when two classes graduated in 1944 (fig. 2). Prior to 1930, in addition to the number of graduates of approved medical schools, the figures included graduates of schools not meeting class A requirements. In 1910, almost 30 percent of medical school graduates were from class B and class C schools; by 1920, only 12 percent.

Dentists

There were about 87,000 dentists in the United States in 1950—57 per 100,000 population. This is a slight increase over the 1940 rate of 53, but no gain over the 1930 high of 58 (fig. 1). These dentists are unevenly located in relation to population. Low ratios exist in the South, in rural counties, and in low-income areas.

The student body of 41 approved dental schools numbered 12,169 in 1950-51, with 2,830 graduates in 1951. The 1951 graduating class was nearly double the 1949 class and, during the last two decades, it was exceeded only by the peak level of 3,212 in 1945 (fig. 2).

Nurses

Nurses outnumber any other single group of health workers. In 1950, active graduate nurses numbered about 322,300 in addition to about 103,000 students in the 1,170 State-accredited schools. There were 279 active graduate and student nurses per 100,000 population in 1950 (fig. 1). Between 1920 and 1940 the ratio was doubled.

The number of graduates rose steadily until the mid-thirties. Be-

tween 1935 and 1947, the number more than doubled—from less than 20,000 in 1935 and in 1936 to nearly 41,000. In 1948 and 1949, there was a decline, followed by an upward trend, with nearly 26,000 students graduated in 1950.

Other Personnel

Veterinary medicine is a relatively new profession. At the present time, there are more than 15,000 practitioners in this group. The estimated number of sanitary engineers is about 5,000. Forthcoming tabulations of the 1950 Census of Popu-

lation will give counts of many additional health occupation groups.

Health Department Personnel

Relatively few physicians, dentists, and nurses are employed full time in State and local health departments. According to the annual reports submitted by health departments to the Public Health Service, the total number of persons employed full time was 51,370 in 1951 and 46,063 in 1947. In 1951, State health departments accounted for 18,903 and local health departments for 32,467, with the types of personnel classification shown on the next page.

United States Delegation to Fifth World Health Assembly

Dr. Leonard A. Scheele, Surgeon General, Public Health Service, Federal Security Agency, was designated by the President to serve as chairman of the United States delegation to the Fifth World Health Assembly, which convened at Geneva, Switzerland, May 5, 1952. The Health Assembly is the policy determining body of the World Health Organization.

Other United States delegates to the Assembly are Fannie Hurst Danielson, New York City, and Dr. E. G. McGavran, dean, School of Public Health, University of North Carolina, Chapel Hill, N. C. Alternates are Dr. Frederick J. Brady and Dr. H. Van Zile Hyde, international health representatives, Division of International Health, Public Health Service, Federal Security Agency, and Howard B. Calderwood, Office of United Nations Economic and Social Affairs, Department of State.

Advisory members of the United States delegation are Donald C. Blaisdell, United States representative for Specialized Agency Affairs at Geneva; Dr. Melvin A. Casberg, chairman, Armed Forces Medical Policy Council, Department of Defense; Dr. Rolf Eliassen, professor of sanitary engineering, Massachusetts Institute of Technology, Cambridge, Mass.; Dr. George Foster, director, Institute of Anthropology, Smithsonian Institution; Joseph S. Henderson, assistant chief, Division of International Administration, Department of State; Dr. Leonard W. Larson, member, board of trustees, American Medical Association; Dr. Lloyd C. Miller, director of revision, Pharmacopoeia of the United States of America, New York City; Dr. Thomas F. Sellers, director, State Department of Public Health, Atlanta, Ga.; Dr. Knud Stowman, international health representative, Division of International Health, Public Health Service, Federal Security Agency; and Ruth Taylor, chief nursing section, Children's Bureau, Federal Security Agency.

Secretary of the delegation is Walter W. Sohl, Division of International Conferences, Department of State.

Hagerstown Health Studies

For the past 30 years, Hagerstown, Maryland, and Washington County, of which it is a part, have served as a community research laboratory for the investigation of public health problems. Beginning with a comprehensive study of illness in 1921, and expanding into a consecutive series of investigations on the prevalence of illness and impairments in the surveyed families, the Hagerstown surveys pioneered in providing long-term data on the progressive effect of illness.

This annotated bibliography has been compiled to give reference sources to the published findings and descriptions of studies and demonstrations in Hagerstown. The citations are classified in seven main sections: descriptions of the studies; morbidity surveys of families; biological factors in public health; school absenteeism and morbidity; height and weight of school children; dental examinations; and specific diseases and conditions. The listings also include a few references, without annotations, to reports of studies made in Washington County or Hagerstown that do not identify data for that community. Data on file in the Hagerstown office of the Public Health Service, available for statistical analysis, is listed.

Research Grants Awarded by the Public Health Service, 1951

This is a compilation of 1,695 research grants and 544 fellowships awarded by the National Institutes of Health of the Public Health Service, from fiscal year 1951 funds. Amounts approved for research

grants totaled \$17,129,554, of which \$5,363,642 were for general (non-categorical) grants and the remainder, \$11,765,912, in the categorical fields of arthritis and metabolic diseases, neurological diseases and blindness, cancer, dental research, microbiology, heart, and mental health. Fellowship awards totaled \$1,568,371.

Better Health For 5 to 14 Cents a Year Through Fluoridated Water

Useful as a guide to communities considering a fluoridation program, this publication contains information on the effectiveness of fluorides in preventing dental caries, the compounds that can be used, and the types of feeders which are recommended. Tests for determining the fluoride content of water are discussed, as are the costs involved. A list of some of the cities which have added fluorides to their water supplies and references to sources of feeder equipment are also given.

• • •

Better Health For 5 to 14 Cents a Year through Fluoridated Water. (Public Health Service Publication No. 62) first printing, February 1951, revised April 1951. 24 pages; illustrated; tables. 15 cents.

for the general public

Looking Forward To the Later Years

This pamphlet was written to help older people help themselves. It does not contain technical or medical information on the physiology of growing old, but offers suggestions on how the person approaching the later years can prepare himself to meet this challenge. The pamphlet

suggests that the older person "take stock" of himself by taking inventories of his health status, financial standing, relationships with his family, leisure-time activities, and social contacts. Hints are also given on ways in which the older person can make his postretirement life more pleasant—by being independent, taking play (hobbies, etc.) seriously, continuing to learn, getting along with others, learning to live with illness and disabilities, seeking help when needed, and giving help to others. Persons in the community who can be of assistance are suggested. Additional references to materials on the later years are listed.

• • •

Looking Forward to the Later Years. (Public Health Service Publication No. 116) 1952. 12 pages. 5 cents.

Sinus Infection (Sinusitis)

The information contained in this leaflet includes a description of the sinuses, and the manner in which they can become infected. A number of causes of sinus trouble are given, along with the warning signs, such as headache or pain over the infected sinus, pain in the cheek, upper teeth, or elsewhere in the head. Some preventive measures are suggested and the treatment which the patient's physician may give him is discussed.

• • •

Sinus Infection (Sinusitis). Health Information Series No. 34 (Public Health Service Publication No. 172). Reprinted 1952. 1-fold leaflet, 5 cents; \$1.25 per 100.

Tetanus (Lockjaw)

The seriousness of tetanus is stressed in this brief leaflet, which describes the disease and the source of infection and symptoms. Immunization is advised, particularly for those who live or work in areas where there is a special risk from tetanus. The use of antitetanus serums for treatment of persons who

have suffered punctured or torn wounds is discussed. The reader is advised to consult his health officer to determine whether he should be immunized.

• • •

Tetanus (lockjaw). Health Information Series No. 45 (Public Health Service Publication No. 159). Reprinted 1952. 1-fold leaflet. 5 cents; \$1.50 per 100.

Neuralgia and Neuritis

Neuralgia and neuritis are described as painful disorders of one or more nerves. Symptoms and causes of facial neuralgia, localized and generalized neuritis, and sciatica are discussed. Warning is given that these symptoms may often suggest or mimic some other disease. Preventive measures suggested are regular examinations by a physician; avoidance of stress, strain, overfatigue, undue exposure to cold and damp; proper protection from dangerous chemicals; a sufficient quantity of B-vitamin foods.

• • •

Neuralgia and Neuritis. Health Information Series No. 62 (Public Health Service Publication No. 161). Reprinted 1952. 1-fold leaflet. 5 cents; \$1.25 per 100.

Allergy

Prepared to answer inquiries on the general subject of allergy, this health information leaflet describes an allergic person, and his reactions. Some of the possible causes of allergies, such as heredity, infection, and foods eaten in excess, are discussed. The most common illness caused by allergens, hay fever, asthma, food allergies, and skin allergies are considered briefly. Specific treatment is not discussed, but the importance of cooperation between the patient and his physician is stressed.

• • •

Allergy. Health Information Series No. 32 (Public Health Service Pub-

lication No. 168). Reprinted 1952. 1-fold leaflet. 5 cents; \$1.25 per 100.

Amoebiasis

Amoebiasis and its severe form, amoebic dysentery, are discussed in terms of incidence and locality of occurrence. The cycle of infection and symptoms of both forms are given with the advice that final diagnosis can be made only by a physician.

Drug therapy and preventive measures, such as proper sanitary precautions in regard to food and water, are discussed. In areas where sanitation is poor, the boiling of drinking water and the thorough cooking of all foods are a must. Raw, leafy vegetables should be shunned although nonleafy vegetables and fruits can be eaten if scraped or peeled. Screening is also a necessary safety measure.

• • •

Amoebiasis. Health Information Series No. 40 (Public Health Service Publication No. 157). Revised 1952. 1-fold leaflet. 5 cents; \$1.25 per 100.

Varicose Veins

Although varicose veins have been recognized since ancient times, the causes are not yet definitely known. Heredity, abdominal tumors or chronic chest conditions, and constricting clothing are suggested as possible factors.

Symptoms, such as a burning, stinging sensation and aches and cramps, are discussed. Varicose veins of long standing lead to discoloration of the legs, eczema of the skin, and eventually to ulcers. A complete physical examination is advised.

• • •

Varicose veins. Health Information Series, No. 50 (Public Health Service Publication No. 154). Revised 1952. 1-fold leaflet. 5 cents; \$1.25 per 100.

Tapeworm

A physical description, the source of infection, and life cycle of the parasites are given for each of the three commonest types of tapeworms; beef, dwarf, and fish. Verification of diagnosis and immediate treatment by a physician are advised. Simple rules for the prevention of tapeworm are: Don't eat raw beef, pork or fish; cook food thoroughly; use modern sanitation measures; buy only meats produced under Federal or equivalent inspection.

• • •

Tapeworm. Health Information Series No. 48 (Public Health Service Publication No. 158). Revised 1952. 1-fold leaflet. 5 cents; \$1.50 per 100.

Tularemia

The modes of transmission of tularemia, the wild animals and insects which carry the disease, and the persons usually infected are discussed in this leaflet. The symptoms are ulcers, enlarged lymph glands, and fever tending toward prostration.

Diagnosis is aided by certain laboratory tests. Streptomycin is indicated as of value in treatment. Prevention is almost entirely a matter of personal precaution. Permanent immunity follows recovery.

• • •

Tularemia. Health Information Series No. 44 (Public Health Service Publication No. 135). Revised September 1951. 5 cents; \$1.25 per 100.

Publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication (including its Public Health Service publication number). Single copies of most publications can be obtained without charge from the Public Inquiries Branch, Public Health Service, Washington 25, D. C.

Public Health Service

Research Grants and Fellowships

On the following pages, Public Health Reports publishes the list of new research grants recommended by the National Advisory Councils of the Public Health Service and approved for payment by the Surgeon General. Lists of fellowship awards are also included. Announcements of new grants and fellowships are published after each of the three meetings held annually by the National Advisory Councils. The present listing represents actions of the February 1952 sessions.

This material has been prepared by the Division of Research Grants, National Institutes of Health.

The Public Health Service research grants program is administered by the National Institutes of Health. Its purpose is to provide financial assistance for research in the health sciences to non-Federal institutions and individual scientists. The major objectives are:

1. To expand research activities in universities and other institutions.
2. To stimulate the initiation of research in small colleges where previous research programs have been limited or nonexistent.
3. To encourage investigators to undertake research in neglected fields.
4. To provide training for scientific personnel.

National Advisory Councils

National Advisory Councils, established by law and composed of outstanding citizens skilled in the medical sciences education, and public affairs, examine all applications and recommend appropriate action. The Surgeon General may award grants only when they are recommended by one of the seven councils:

National Advisory Arthritis and Metabolic Diseases Council, National Advisory Cancer Council, National Advisory Dental Research Council, National Advisory Health Council, National Advisory Heart Council, National Advisory Mental Health Council, and National Advisory Neurological Diseases and Blindness Council.

Study Sections

In order that these advisory councils may have the benefit of the best scientific advice on applications for research grants, outstanding authorities in each of the major fields of research have been appointed as members of special study sections. Appointments are made to provide for rotation of membership. The majority of these special consultants are nongovernmental scientists selected by the Surgeon General on a nation-wide basis.

These study sections have accepted the responsibility (1) for reviewing applications for research grants in their respective fields, and forwarding their recommendations for approval, modification, further study, or disapproval to the appropriate National Advisory Council; and (2) for surveying, as scientific leaders, the status of research in their fields in order to determine areas in which research activities should be expanded. Study sections meet prior to the regularly scheduled meetings of the National Advisory Councils.

The applicant describes the research which he plans to do and provides information as to his training, experience, accomplishments, his work situation, and the facilities available. These factors are considered in detail with care by the study sections. Since there is never sufficient money to grant all worth-while re-

quests, it is necessary to provide a mechanism whereby requests compete on the basis of merit. The study sections and councils prepare a merit roll and the Surgeon General makes grants as far down the list as funds permit.

In order to insure scientific freedom and thereby promote the highest quality of research in both fundamental and applied fields, the investigators are not required to follow their original proposal but rather are free to pursue the research in whatever manner they wish and to publish their findings without clearance with the Government.

The Scope of Grants

In earlier years when the major causes of death were infectious diseases and the civilized world was continuously afflicted with severe epidemics and a very high infant mortality rate, scientists gave their attention primarily to these matters. As a result of their efforts, effective means for treating and preventing many of these diseases were discovered. General sanitation and nutrition improved and people began to live longer.

During the past few years there has developed among health agencies, physicians, and scientists an increasing preoccupation with chronic diseases of middle and old age. These diseases have increased as causes of death and disability largely as a direct consequence of the increased average life span of man. In order to keep pace with this changing emphasis of research, Congress has created in the Public Health Service's National Institutes of Health a series of new institutes concerned primarily with research in diseases such as cancer, arthritis, arteriosclerosis, and blindness.

It has not been the intention of Congress or the Public Health Service to decrease research efforts in fields such as infectious diseases but rather to maintain them at full vigor while stimulating additional research in the newer fields. The National Microbiological Institute and the Division of Research Grants have, therefore, continued to provide research support in the field of infectious disease and general medical research.

It was recognized that this expansion of re-

search effort could not be accomplished without expanding the research potential of the country. Research grants have made it possible for well-trained investigators to obtain additional assistants and equipment so that they could work at maximum efficiency. This has resulted in the training of many new investigators.

Research Fellowships

In addition, the Public Health Service conducts a research fellowship program to provide financial assistance to the most able and promising students and scholars during their training period so that they can enter a career of research in medical and allied fields. These fellowships are awarded on a competitive basis upon the recommendation of Institute specialty boards and committees of scientists at the National Institutes of Health. Annual stipends range from \$1,600 up. Scientists anywhere in the world are eligible to compete. American citizens may receive training under these fellowships at any recognized institution in the world. A small number of fellowships have been awarded to foreign students for training in the United States.

Six Years of Grants

It is gratifying to note some of the developments during the first 6 years of the expanded grant program.

The volume of research has increased substantially. This increase has not been restricted to large institutions with well-established research programs. To be sure, such institutions have made a great contribution to this increased effort but in addition—and perhaps of greater consequence in the long view—sound, substantial research programs have developed in other institutions widely distributed geographically and where little or no research existed before.

The availability of Federal funds has not diminished the degree of non-Federal support. In the period from 1946 to 1951, while Federal support was increasing twentyfold, there was a simultaneous fivefold increase of funds from private sources. Federal recognition of local ability has often provided a stimulus for increased local support.

FOOD

in Civil Defense

Selected papers from the United Kingdom,
United States, and Canadian Combined
Conference on Administrative and Scientific
Aspects of Food in Civil Defense, London,
November 26 through December 13, 1951.

Upon the invitation of the Government of the United Kingdom of Great Britain and Northern Ireland, the Combined Conference on Administrative and Scientific Aspects of Food in Civil Defense was convened in London on November 26, 1951.

Official delegates from the Government of Canada, of the United Kingdom, and of the United States of America participated in sessions which extended through December 13, 1951. The Canadian delegation was led by Maj. Gen. F. F. Worthington, Civil Defense Coordinator of Canada, Ottawa; that of the British by G. S. Bishop, Under Secretary in Charge of Defense Plans, Ministry of Food, London, England; and that of the United States by Paul B. Murphy, food specialist of the Health and Welfare Office, Federal Civil Defense Administration, Washington, D. C.

The conference considered, in the light of the experience of the United Kingdom in World War II and of the subsequent development of plans in all three countries, the administrative

and scientific problems which arise in maintaining food supplies as part of defense measures.

After a broad survey of the problems in plenary session and a general review of experience, the conference organized detailed discussions in three major groups. One considered emergency feeding problems. The second section examined problems of food administration, and the third probed present status and future needs from a scientific standpoint.

Public Health Reports presents in the following pages and in succeeding issues a number of the more significant papers which have now been made available by the three governments.

In selecting the papers for *Public Health Reports* emphasis has been placed on topics of broad interest and practical importance to public health—nutritional considerations, food sanitation in emergencies, research. By way of introduction, a summary of the conference findings and recommendation to the three governments precedes the first group of papers.

The London Food Conference

—A Summary of Findings—

Civil defense organizations must be prepared to feed entire populations for days and perhaps weeks in the event of atomic attacks on major cities.

To be ready for any atomic emergency, mass feeding plans must be perfected, which will utilize the full resources of industry and all voluntary agencies.

Although individuals are responsible for their own survival, the feeding of stricken populations would present such immense supply, transportation, and distribution problems that large areas and even entire nations would have to assist.

Such were some of the general conclusions of the conference. Following are high lights in the three main areas of discussion—emergency feeding, administration, and scientific problems. The wording of the report from the conference to the three governments is closely followed or is paraphrased.

Emergency Feeding

Emergency feeding is designed to feed in wartime all members of the civilian population who are unable to obtain meals through normal channels. It is strictly an emergency program and must not last any longer than needed. The earliest possible return to normal is vital.

Plans for emergency feeding must not be confined to those areas which have been designated as target areas. The urgent needs of the homeless and the injured who move or are moved into other areas and the obligation of all areas to provide mutual aid require that every community develop complete feeding plans.

The steady development of new and more powerful weapons makes it essential that the very sound plans developed in Great Britain for emergency feeding during World War II be

Queen's Messenger Convoys

Queen's Messenger convoys were inaugurated personally by Her Majesty during the worst raids of the last war in 1941. Their function is to bring immediate relief after serious air attack. They provide light, hot meals. The Ministry of Food, under whose direction the convoys were administered, found that a convoy's early arrival after an attack helps to keep up morale by showing that relief is on the way, and that something is being done.

The convoy is designed to provide between 6,000 and 8,000 light meals of soup or tea and sandwiches at one operation. Each canteen also carries infant foods in feeding bottles. A self-contained unit, the convoy carries sufficient food to operate at capacity for 2 days, and sufficient hard fuel for 6 hours' continuous operation. Extra fuel is obtained at the site.

broadened. The vastly greater number of persons who may be without food or the normal means to prepare and serve it, as the result of atomic attack, demands that fuller consideration be given generally to the responsibility of the individual for his own survival, and of the community and the nation for the essential feeding of its citizens.

On the other hand, the essence of preparation must be the anticipation of the unexpected. Too great a preoccupation with atomic attack may lead to neglect of this fact. On both sides of the ocean there must be preparation to feed people under any condition.

Leadership and Decentralization

All three nations have recognized the importance of local governmental responsibility.

Top: These eight vehicles represent one-half of a Queen's Messenger food convoy. A full convoy consists of an office van, two equipment stores vans, eight canteen vans, two 500-gallon water tankers, two food stores vans, and a welfare van, plus three motorcycles.

Center: The Queen's Messenger kitchen van is used as a separate unit and not as part of the convoy. It is capable of turning out 500 main meals (meat, vegetables, and a sweet) per cooking or 3,000 meals per 24 hours. This picture shows the over-all unit and the Merry-weather boiler directly behind the cab.

Bottom: The rear interior of the kitchen van is shown here. The 50-gallon hot-water boiler, hot plate, sterilizer, and part of the steaming oven unit can be seen.

All photographs courtesy of the British Ministry of Food.

The conference emphasized the importance of further delegation of responsibility to the heads of the various local government departments. Civil defense, they underscored, is a civilian responsibility. Food plans must not include operational dependence upon the armed forces.

Strong, imaginative, disciplined, and trusted leadership from the city block to the nation is imperative. Great disruption demands great local responsibility. The community that is not able to feed its people threatens its own existence and endangers the nation.

Recruitment and Training

Training must be training for survival—training in improvisation. It is of first importance to train people to prepare and serve meals under extraordinary conditions. Every community has cooks ranging from the housewife to the commercial chef, but few people know how to improvise or how to operate when the usual hygienic safeguards are lacking. Training must be simple, clear, and practical. The basic staff of instructors need not know the theories of modern warfare. They must know how to do what they must do, and this they can learn only by building or using improvised equipment.

Improvisation

The first essential in emergency feeding plans is the ability to provide food under primitive conditions. It must be assumed that utilities will be destroyed throughout the community and that food must be prepared quickly on whatever equipment is available in the rubble. Safe water is of paramount importance. An ample supply of transportable cooking units to supplement improvised elements must be provided. Plans must be made to use alternative fuels in fixed cooking installations which now depend on gas or electricity.

Commercial Facilities

No present plans for emergency feeding can be complete unless they include the full utilization of the commercial caterers, restaurateurs, and all others who sell meals. It is imperative that every commercial restaurant be opened for business as quickly as possible after an attack.

Plans for the future must contemplate that

great numbers of people must be fed, and that publicly owned facilities, such as school lunchrooms, may be inadequate. These basic feeding centers, both public and commercial, must be supplemented by additional feeding centers, mobile canteens, food convoys, and improvised cooking facilities.

Voluntary Agencies

While the basic responsibility for emergency feeding, as with all civil defense, rests with government, the personnel and skills available in voluntary agencies must be brought into full employment. Although civil defense authorities cannot divest themselves of responsibility by the delegation of authority to voluntary agencies, it is felt that broader use of these groups can be made.

Supply and Stockpiling

Food must be available where it is needed or there can be no emergency feeding. Supply organization must be decentralized in such a way that each emergency feeding officer at a feeding center knows how and from whom he will get his food—and will actually get it.

Food stockpiling in each country is influenced greatly by the supply situation. The British, for example, rely primarily on ordinary channels of trade for distribution, but reserves of powdered soup and canned meat in gravy are being held. Plans have been made to insure that necessary supplies of foodstuffs be made available to emergency feeding centers and rest centers to meet the first impact of need.

Availability of pots, pans, dishes, cups, and cutlery pose difficult problems. Great quantities of water will be needed for cleansing and sterilizing. Disposable articles will be of great value if they can be available when and where needed.

Water is a vital necessity. The supply in many communities can be destroyed or readily contaminated, and requires much time for restoration. This is a major supply and reserve problem.

Food Items and Menus

What foods to use in an emergency, the conference noted, is perhaps the least important consideration because we can only serve foods

which are available at the time. However, two principles governing the "menu" emerged from the discussions.

First, a hot, sweet drink must be available for great numbers of people as quickly as possible after the attack. This is a "must" for it helps to relieve shock and restore morale and public order. Preparations for this cannot be casual.

Second, a good, hot meal—not a snack—should be provided within a few hours. British experience shows that this meal often marks the point at which an individual can and will pull himself together and set about the business of solving his own problems.

Improvisation does not mean that menus do not need to be prepared and placed in the hands of the people who must prepare meals. Improvisation is resourceful deviation from a plan, not frantic activity. The full resources of people trained in nutrition and home eco-

Two 500-gallon mobile water tankers are part of each Queen's Messenger convoy. The internally galvanized tank is mounted on a 3-ton chassis. It is provided with a pump capable of delivering 1,000 gallons per hour.

nomics should be called into service in planning meals as well as supervising feeding operations and training workers.

Food for Special Groups

Problems relating to the feeding of a number of special groups remain largely unresolved. Civil defense workers will require regular and substantial meals; the injured in hospitals will require special feeding as will infants and expectant mothers. Further study must be given to these problems in close coordination with the other civil defense services concerned, especially by those responsible for medical and public health services.

Food Administration

The primary object of good planning in civil defense is the preservation of civilian fitness, morale, and the will to win. It is necessary to meet the physiological need for sufficient food to sustain the national effort, but this is not enough. The people must have faith in the rapid restoration of normal facilities and have confidence that their accustomed foods will be in the shops with fair shares for all.

Food supplies must be maintained under all conditions. It is important to restore in the shortest possible time the regular production, processing, and commercial distribution of all the basic foods. It must always be possible to

This is the interior (looking forward) of one of the eight canteen vans in a Queen's Messenger "food flying squad" convoy. The canteen is mounted on a 2-ton chassis. The panel section (left) lifts to form a shelter over the counter. The insulated containers seen in racks on either side are used to carry tea, soups, stews, and sandwiches.

meet the needs of those able to provide for themselves, of catering establishments, and of the emergency feeding services.

In general, the administration and supply group felt, the key to the successful operation of wartime food planning lies in the wholehearted cooperation and self-organization of the individual food industries and trades working with the government units concerned.

Planning and Leadership

Planning in advance is essential and must be integrated so that the local and regional plans fit into the national plan. There must be coordination at each action level.

It is impossible to make detailed arrangements for every eventuality. The plan must be so prepared that the responsible leader on the spot is free to improvise and make adjustments to meet special circumstances. Only by decentralization can an effective answer be found in time.

Good leadership is of the utmost importance. The leader must have the human touch and evident sincerity, the moral courage to make immediate decisions, and that quality which succeeds in getting others to do what is wanted as part of a common objective.

Self-Help and Mutual Aid

Self-help is important because it is good for the individual's morale and reduces the burden on the civil defense services. It should range from the household to the nation.

The conference report noted that in the United Kingdom the application of this principle to the food industries and trades produced successful mutual assistance during the last war. Whenever a trader suffered from enemy action his normal competitors came to his aid. This might entail the provision of warehousing or counterspace, delivery services, and even processing of food. In many instances, the traders who assisted in this way refused to accept any portion of the profits from the additional business. Many of the agreements were oral, but were always fulfilled.

Dispersal and Transportation

Dispersal is an important safeguard against mass destruction of food and against the inter-

ruption of supplies through serious dislocation of transport.

Under wartime conditions, transport and communications become of first importance. The aim is to see that the food is delivered with a minimum demand upon the transport system.

This rear view of a stores van in a Queen's Messenger convoy shows the 2-ton truck loaded with Soyer Boilers, part of its regular equipment. The vans are based near the scene of an attack and the boilers are used to heat tea, soups, and stews which are then loaded into insulated containers and transported by canteen vans to sites where emergency feeding is necessary.

Bread and Milk

Immediately following a heavy attack, the most urgent food supply problems concern bread and milk—the two basic foods for adults and children which cannot easily be stored. Regular deliveries of these two foods are im-

portant in sustaining morale. The demand for bread under these circumstances, the British reported, has been found to increase at least twofold.

Salvage and Glass Damage

The prompt application of proper salvage methods can reduce considerably the loss of foodstuffs from enemy action or ordinary fires. It has been estimated that about 75 percent of the food lost in the first attacks on Britain could have been avoided if measures later developed for the recovery of damaged foods had been applied.

Special attention should be given to the problem of destruction of food by glass splinters. This was a cause of serious loss in Britain. Even packaged and canned foods were frequently perforated by glass particles.

Scientific Aspects

For the maintenance of health, consumer satisfaction, and a high level of work output, the provision of adequate calories is the primary requirement, the scientific delegates agreed. This assumes that adequate amounts of the essential nutrients are contained in the available foods and that the foods are so distributed as to protect nutritionally vulnerable groups.

On the other hand, the conference held, the primary consideration in short-term emergency feeding is the provision of acceptable foods sufficient to allay hunger and sustain morale. Detailed consideration of nutrient values is unnecessary since specific nutritional deficiencies will not develop during this short period in previously well-nourished individuals.

Special Population Groups

Infants are unusually susceptible to even a temporary interruption of their food supply and should receive special consideration in planning supplies for emergency feeding. However, it is not anticipated that with a previously well-nourished population any specific nutritional deficiencies would become evident within a month. It should not, therefore, be necessary to take any special measures to distribute vitamin concentrates to mothers or infants during this period.

Emergency workers and those engaged in heavy work must be well fed, of course, but there is no adequate basis for the classification of workers or industries into arbitrary groups, such as heavy, medium, and light, and therefore for the assessment of their energy requirements. More up-to-date information is needed.

Measuring Nutritional Status

The conferees agreed that experience has demonstrated the necessity for determining the nutritional status of populations under wartime conditions as a guide in the distribution of limited food supplies. Simple methods are essential for this purpose.

Accurate measurements of weight and height should form a major criterion in such an assessment. Combined with clinical appraisements of health, such measurements would have a notable value in assessing the effects of changes in food practices. At the present time base-line reference data of weights and heights, to which changes could be related, are either nonexistent or inadequate.

Steps should be taken now to collect the necessary base-line data and any other appropriate anthropometric measurements in such fashion as to permit comparisons between countries. Research also should be encouraged on additional tests which might supplement the anthropometric data, such as measurements of hemoglobin, enzymes, and specific nutrients.

Emergency Food Hygiene

In discussing sanitation problems in emergencies, the conference pointed out the need to allay public anxiety about the hazards of atomic warfare to food production and supplies, and to place such hazards in proper perspective.

The conferees considered that induced radiation does not constitute an appreciable practical hazard to food. "Fall out" contamination of food from a high atomic burst is usually slight.

Undestroyed food in unbroken containers may be consumed with safety if the container is cleaned externally. This same principle can be applied to food in bulk storage if the superficial layers are removed.

A ground or underwater burst, on the other hand, may result in heavy contamination of a

considerable area. In temporarily uninhabitable areas food will not pose an immediate problem. Monitoring should be used as a guide in entering these areas and assessing the safety of the food found there.

Biological Warfare Hazards

Biological warfare may involve a twofold risk to a country's food supplies: a reduction in agricultural output due to infection of crops or livestock, and contamination of food that will involve a direct hazard to human health.

The conference reported that the hazards to food from biological warfare and bacterial contamination could best be reduced by (a) the full development of public health and similar services and the utilization of existing knowledge in detection and control; (b) the inclusion of instruction in the hygienic handling of food as part of civil defense training; and (c) the universal application of heat to all suspected foods.

Chemical Warfare Risks

Chemical warfare hazards through contamination apply both to agriculture and to man, the conference noted. The risk to the former is probably small, and the risk to man is considered to be most likely in terms of antipersonnel weapons. Where hazards to foods are involved, methods of identification, protection, and decontamination are the main defensive measures.

Concentration of Food

Although the dehydration industries have been severely curtailed since the last war, the conference reported renewed interest in dehydrated products for use by the armed services and civil defense. There is need for further research—including far more background research—into means of improving palatability, ease of reconstitution, keeping quality, and packaging.

Scientific Problems in Food Defense

By NORMAN C. WRIGHT, D.Sc., Ph.D.

It will be convenient to group the scientific problems of food defense under three broad heads: first, those concerned with the maintenance of an adequate and acceptable diet for all sections of the population, and specifically with meeting essential nutritional needs under emergency conditions; second, those involved in the reduction of the bulk and weight of essential foods, in their storage properties, and in their

distribution in a convenient, attractive, and easily handled form; and third, those related to the protection of food stocks and to the salvage of damaged supplies.

Many of the problems falling under these three heads are closely paralleled by the wider problems of maintaining an adequate national food supply under war conditions. Moreover, they are relevant even in the more limited field of emergency feeding of the fighting services where specially concentrated ration packs are used. This is, indeed, the reason why the civil departments concerned with research and development in food science in the United Kingdom share with the services the responsibility for investigating the scientific problems involved in food defense—a partnership which has in practice proved of great mutual benefit.

Dr. Wright is the chief scientific adviser to the Ministry of Food of the United Kingdom. He presented this paper in London, November 30, 1951, at the plenary session of the Combined Conference on Administrative and Scientific Aspects of Food in Civil Defense.

Maintenance of Adequate Diet

Basically, the adequacy of a diet is measured in terms of specific nutrients, that is, its calorie value and its content of protein, mineral constituents, and vitamins. In considering the long-term needs of a whole population under war conditions, all these must be taken into account. But for relatively short-term purposes, such as those involved in temporary emergency feeding, evidence indicates that it is the total calorie value of the diet which is of primary importance and which can be used as the best index of nutritional adequacy. This applies particularly to civil defense and essential industrial workers who have to undertake heavy physical tasks, frequently under conditions of stress. From the planning aspect, it is therefore essential that we possess a clear view of the levels of calorie requirements of different sections of the population under such conditions. We also need an indication of the probable effects of reduced calorie levels on physical efficiency, industrial output, and morale, particularly when the interruption of normal feeding is likely to be prolonged as in hastily evacuated industries or in areas cut off from normal supplies by enemy action.

Apart from the consideration of total food intake as measured in terms of calories, provision must also be made for safeguarding the health of the so-called vulnerable groups in emergency conditions—expectant and nursing mothers, infants, and invalids. The nutritional needs of these groups are well recognized. The technical problems involved are concerned rather with the provision of substitutes for essential foods, such as liquid milk, should normal distribution fail, and with devising packed rations for these special groups during evacuation or temporary isolation. A further group whose requirements under emergency conditions need to be assessed and met are those injured as a result of enemy attack, whether from shock, physical injury, or damage from special hazards such as radiation. These aspects of special dietary requirements under emergency conditions clearly form the indispensable basis of any emergency feeding plans.

But while a sufficient supply of essential nutrients is the prerequisite of an adequate diet,

it is no less important that such nutrients should be furnished in an acceptable form. It cannot be too strongly emphasized that one of the most effective means of maintaining the morale of a population under stress is that their diet, and the foods which compose it, should deviate as little as possible from normal food habits. Thus, in the United Kingdom great stress was laid in the last war on the maintenance of daily deliveries of bread and of milk. In the same way such foods as are provided at emergency feeding centers should be those to which the people are accustomed and attracted; a sudden emergency is no time for introducing untried novelties. A typical example which may be quoted to illustrate this point is the provision of dried soups for emergency feeding. It is right and natural that nutritional experts should stress the importance of insuring that such soups have a high nutritive value, but it is at least equally essential that this should be combined with universal acceptability. Indeed, for short-term emergency purposes the first essential is that the foods supplied should be attractive to the consumer. The problem of the food scientists is how to incorporate into such an attractive dish the nutritive properties which furnish maximum sustenance.

Reducing Bulk and Weight

This principle is equally important in considering the second group of problems listed earlier: those involved in reducing the bulk and weight of essential foods and in improving their storage properties. For many foods, notably animal products—such as milk, eggs, and fish—vegetables and fruit, the most effective method of reducing bulk and weight is by eliminating the contained water. But it is found that the most acceptable of the resulting artificially dried products are those which on reconstitution most closely simulate the natural food.

Thus, milk powder manufactured by the spray drying process furnishes on reconstitution a product practically indistinguishable from liquid milk and has a ready sale. The present difficulties in reconstituting it into liquid form, however, still make it less acceptable to many housewives than, for instance,

canned evaporated milk. Dried egg powder, the uses of which as a substitute for shell eggs are more limited, only achieved popularity as a result of the serious shell egg shortage and after the housewife had gained considerable experience in its use. In spite of its ease of reconstitution, potato mash powder still has only a limited sale. Moreover, the trend of demand in the British fighting services is for dried potato slices rather than for mash—an indication of the general preference for a product which on reconstitution most closely retains its original appearance and properties. There is little doubt that the same general argument would apply to other dried vegetables (as it does to dried fruits) and to dried meat and fish if offered for sale to the public.

Three Essentials

These examples have been quoted to show that, in devising methods of reducing bulk and weight, at least three essentials must be taken into account: first, the product must be capable of reconstitution into a form to which the consumer is accustomed; second, the method of reconstitution into this form must be simple and rapid; and third, the product must be capable of storage for relatively long periods without deterioration in flavor or texture. If these conditions could be met, such dried products could, from the standpoint of civil defense, be of real value. In the first place they would form an attractive variant in emergency meals or in the supplies used for the initial feeding of evacuated populations—or indeed for temporarily isolated populations who can only be fed by airlift operations. In the second place, if the housewife were once accustomed to their use in the home, they would form a valuable item in household larder stocks to meet temporary or emergency shortages. For both these purposes it is, however, essential that the products be sufficiently attractive to find a market under peacetime conditions so that in an emergency they would not be considered simply as undesirable substitutes for the genuine product. They must, in brief, possess sufficient advantages to stand on their own merits.

The production of artificially dried foods of

improved acceptability constitutes one desirable technical development in this field. There are, however, a number of other directions in which science should be able to increase the availability of foods for emergency purposes. Bread constitutes the main basis of all Western diets, but at present we are completely dependent on static or, in an emergency, mobile bakeries for our day-to-day supplies. While the bulk of a nation's bread will always need to be freshly baked, it might well be desirable to have available an alternative long-keeping product for which local baking facilities and fuel supplies are not needed. Canned bread and foil-wrapped bread provide two methods of meeting this need. Another alternative is the more extended use of antistaling and antimold agents. While the use of such agents is probably not desirable as a national policy in peacetime, it ought clearly to be given consideration as a possible emergency measure. The same comment applies to antioxidants, which are capable of delaying the development of oxidative rancidity and tallowiness in the long-term storage of fat-containing foods.

Fields for Study

Any assessment of the effectiveness of such special measures, and of the possible risks which they might entail to the consumer, must be based on scientific investigations of a relatively fundamental nature. Systematic studies are, however, equally necessary in solving many of the more practical problems involved in emergency feeding. Thus, the selection of equipment for the preparation and serving of meals at emergency feeding centers necessitates careful tests of their suitability and reliability. This applies not only to such considerations as the effectiveness of the insulation of containers designed to hold hot beverages, but even to such subjects as the heat conduction of beverages in relation to their "thickness" (or viscosity) and their rate of "settling"—factors which have been shown to influence to a marked degree their heat-retaining properties. Again, when emergency equipment has to be procured in very large quantities (e. g., individual feeding utensils) it is essential that the choice of the various items should

be based on systematic studies of their design, robustness, and ease of stowage.

The problems so far discussed have been concerned mainly with the production and properties of foods suitable for civil defense feeding. A no less important field of study is the problem involved in the packaging and transport of food, whether for general civilian feeding, emergency feeding, or the supply of food to the fighting services.

Packaging and Transport

As regards packaging, the outstanding problem in the United Kingdom is the acute shortage of packaging materials, particularly of tin plate and of the fibrous materials required for sacks and wrapping. This shortage can only be met by the development and use of substitutes which have the necessary properties of impenetrability to moisture and air and which are sufficiently robust to withstand prolonged storage and subsequent handling. One incidental advantage of the use of such substitutes is, however, that they may lead to the adoption of packaging methods which have certain advantages over those used during the last war. Thus, foil-wrapping and the use of synthetic materials, such as pliofilm, are capable of substantially reducing the weight of, for instance, emergency ration packs—a point which is of importance both for civil defense purposes and for the fighting services.

As regards transport, it is now well recognized that the efficient conduct of a war places a most severe strain on a nation's road and rail services. Experience in the last war showed that one of the limiting factors in securing the optimum use of these services and facilities was the time taken in handling freight, which in turn is influenced by the size, shape, weight, and nature of the packages to be handled and by the extent to which freight handling can be mechanized. The existence of an emer-

gency in any given locality due to enemy action, in which, for instance, one sector of the transport system has been badly disorganized, combined with a probable shortage of available manpower in such an affected area, would intensify the need for the greatest efficiency in all freight handling operations.

Protection and Salvage

Finally, there is the third general group of problems, namely, the measures needed for the protection of food stocks from deterioration or damage, and for their disposal if they are unfit for human consumption. The prevention of deterioration is, of course, a wide problem which affects the whole policy of stockpiling on a national basis, but it involves special difficulties when applied to the local storage of food supplies for emergency purposes, since such local stocks may on occasion have to be stored in hastily improvised premises.

Moreover, damage to food stocks resulting from direct enemy action clearly falls within the province of the civil defense services. In the last war such damage was limited to the direct and indirect effects of blast and fire, and much information is available regarding both the nature and extent of the damage likely to be caused by these hazards and the means of minimizing their effects. The development of new hazards resulting from radiation and from bacteriological and chemical contamination has, however, opened up a fresh series of problems on which scientific investigations and guidance will be required. These problems involve not only the determination of the nature and severity of the contamination, but an assessment of the risks involved in consuming the contaminated food. Indeed, the safe disposal of such food may itself involve a very real problem, quite apart from the practicability of salvaging operations.

canned evaporated milk. Dried egg powder, the uses of which as a substitute for shell eggs are more limited, only achieved popularity as a result of the serious shell egg shortage and after the housewife had gained considerable experience in its use. In spite of its ease of reconstitution, potato mash powder still has only a limited sale. Moreover, the trend of demand in the British fighting services is for dried potato slices rather than for mash—an indication of the general preference for a product which on reconstitution most closely retains its original appearance and properties. There is little doubt that the same general argument would apply to other dried vegetables (as it does to dried fruits) and to dried meat and fish if offered for sale to the public.

Three Essentials

These examples have been quoted to show that, in devising methods of reducing bulk and weight, at least three essentials must be taken into account: first, the product must be capable of reconstitution into a form to which the consumer is accustomed; second, the method of reconstitution into this form must be simple and rapid; and third, the product must be capable of storage for relatively long periods without deterioration in flavor or texture. If these conditions could be met, such dried products could, from the standpoint of civil defense, be of real value. In the first place they would form an attractive variant in emergency meals or in the supplies used for the initial feeding of evacuated populations—or indeed for temporarily isolated populations who can only be fed by airlift operations. In the second place, if the housewife were once accustomed to their use in the home, they would form a valuable item in household larder stocks to meet temporary or emergency shortages. For both these purposes it is, however, essential that the products be sufficiently attractive to find a market under peacetime conditions so that in an emergency they would not be considered simply as undesirable substitutes for the genuine product. They must, in brief, possess sufficient advantages to stand on their own merits.

The production of artificially dried foods of

improved acceptability constitutes one desirable technical development in this field. There are, however, a number of other directions in which science should be able to increase the availability of foods for emergency purposes. Bread constitutes the main basis of all Western diets, but at present we are completely dependent on static or, in an emergency, mobile bakeries for our day-to-day supplies. While the bulk of a nation's bread will always need to be freshly baked, it might well be desirable to have available an alternative long-keeping product for which local baking facilities and fuel supplies are not needed. Canned bread and foil-wrapped bread provide two methods of meeting this need. Another alternative is the more extended use of antistaling and antimold agents. While the use of such agents is probably not desirable as a national policy in peacetime, it ought clearly to be given consideration as a possible emergency measure. The same comment applies to antioxidants, which are capable of delaying the development of oxidative rancidity and tallowiness in the long-term storage of fat-containing foods.

Fields for Study

Any assessment of the effectiveness of such special measures, and of the possible risks which they might entail to the consumer, must be based on scientific investigations of a relatively fundamental nature. Systematic studies are, however, equally necessary in solving many of the more practical problems involved in emergency feeding. Thus, the selection of equipment for the preparation and serving of meals at emergency feeding centers necessitates careful tests of their suitability and reliability. This applies not only to such considerations as the effectiveness of the insulation of containers designed to hold hot beverages, but even to such subjects as the heat conduction of beverages in relation to their "thickness" (or viscosity) and their rate of "settling"—factors which have been shown to influence to a marked degree their heat-retaining properties. Again, when emergency equipment has to be procured in very large quantities (e. g., individual feeding utensils) it is essential that the choice of the various items should

specific instances. There is information to support the use of foods high in protein, but the ratios to available carbohydrates and the rate of increasing the caloric content are not well defined.

Radiation Sickness

Numerous claims have been reported in the literature concerning practical benefits to be derived from increased protein, vitamin, and other nutrient intakes. Most of the claims, such as those involving polyphenols, vitamin B₁₂, ascorbic acid, glutathione, cysteine, glucuronic acid, and methionine, have not been adequately confirmed or disproved either for animals or for man. Hence, a systematic study of the individual vitamins and other nutrients should be undertaken to supplement the information that has been reliably established. Each substantial lead should be tested clinically at the earliest opportunity under the auspices of investigators whose work will be widely accepted. The nature of the problem makes it evident, however, that most of the work must be done with experimental animals, rechecking with different species.

Both preventive and therapeutic aspects of the problem should be studied, first in terms of specific nutrients and then with reference to acceptable and available commodities.

Biological Warfare

Special diets were found to have a significant bearing upon convalescence from infectious hepatitis during and after World War II, but there does not seem to be adequate evidence concerning emergency and convalescent diets that would be of benefit in the event of biological warfare attacks. Biological warfare agents which might be used include bacteria, toxins, hormones, and viral agents. At least one very promising lead has developed with regard to virus infection injury and another dealing with bacterial infection. In neither case has the specific nutrient been identified.

Prospects to be studied should include the large-scale use of sulfa drugs and antibiotics. Assured techniques, qualified personnel, and specific plans for rapidly sampling and testing foodstuffs, soil, water, and the atmosphere for

actual or suspected contamination should also be made available.

Chemical Warfare

Emergency and convalescent diets should be evaluated for each major type of chemical warfare agent that can be anticipated. There is reasonable expectation that the dietary measures that would be effective in aiding recovery from exposure to the various types of chemical warfare agents, such as nerve poisons, respiratory poisons, surface irritants, and specific kinds of radiation poisoning, would differ.

Frost Injury and Cold

Claims have been made for dietary measures that afford significant protection against impairment from exposure to cold, or that promote convalescence following injury. A few of the findings appear to be reliable and of practical value, but most of the reports have not been verified (or disproved) to a degree that would guide practical measures. If there should be prolonged warfare in arctic, subarctic, or high-elevation areas, or during a winter season in the temperate zone, information of this type would be of value to both civilian and military personnel. Among the nutrients for which claims have been made, for example, are high-carbohydrate meals, ascorbic acid, vitamin B₁, vitamin B₁₂, pantothenic acid, and vitamin B₆.

Starvation

Presumably there is little immediate risk of severe or chronic starvation of the civilian population within such areas as the United States and Canada. This Nation, however, may be called upon to feed large masses of partially starved civilians in other areas or to feed released civilian groups from military areas, so it is of critical importance that reliable information be at hand to guide feeding practices (*a*) during recovery from starvation; (*b*) during periods of severe demands upon total food resources when work output is urgent; and (*c*) to permit the most efficient adjustment of international food resources in all allied areas, in-

cluding those from which shipments are made.

A major consideration in this field of research is the merit of foods high in animal protein, vitamins, and mineral elements (recommended by many experienced clinicians) compared to low-cost, high-calorie foods, such as the cereals and oils, in achieving optimum convalescence from general starvation. More specifically, the problem is one of having available adequate data so that agreement may be reached among scientists, military officers, and civilians regarding an optimum adjustment of the ratio of calories to other nutrients under widely varying conditions of economic and physiological stress.

Another area for research deals with the requirements to conserve reasonable work output, health, and morale among population groups, adapted to varying degrees of limitation in food resources. This problem may become of strategic importance in the Far East, Near East, and many other sections.

Intravenous Feeding

For convalescent feeding of nearly all victims of simple starvation, intravenous feeding is not advised. However, for relatively rare individuals who cannot ingest food, there is need to develop satisfactory materials and procedures for intravenous feeding to prevent severe body weight loss and extreme weakness. Encouraging headway has been made in the use of fat emulsions, but the problem is not solved to an extent that would permit efficient large-scale production of materials.

Protein Deficiency

There is need to develop an objective and reasonably specific measure of protein deficiency that could serve both in mass nutrition studies and in individual studies. Serum albumin and globulin values do not furnish a satisfactory index of protein adequacy. Possibly electrophoretic and ultracentrifuge studies would permit identification of definite fractions whose variation would correspond in reasonable degree with the quality and quantity of protein ingested.

These studies could well be coordinated with

a comparable approach to identification of the specific blood protein changes during severe catabolic and delayed anabolic phases of protein metabolism induced by stress.

Resistance to Stress

Adrenocortical functions appear to be of major importance in recovery from severe stress and shock induced by burns, trauma, hemorrhage, toxic materials, emotional stress, and exposure to cold. There is incomplete evidence that specific nutrients or groups of specific nutrients, including pantothenic acid, ascorbic acid, pyridoxine, polyphenols, riboflavin, vitamin B₁₂, choline, glucuronic acid, amino acids, fatty acids, and electrolyte balances, are important factors in building and protecting the defense mechanisms. Basically, each essential nutrient is probably necessary for normal functioning of all body tissues, including the specialized organs, but there is immediate need to gain a more specific and quantitative appraisal of the effect of transitory or long-continued high- and low-nutrient intakes upon resistance to specific stresses and upon the subsequent course of recovery. Quantitatively, at least, there is wide variation among the specific nutrients and among the different tissues.

Dehydrated Milk

Of the food commodities that have greatest promise of meeting civilian needs for disaster feeding, in addition to meeting demands for national health and economy during a long period of war or threatened war, dehydrated whole milk of high acceptability and dry, non-fat milk solids are perhaps the most crucial. Both products are needed as supplements to fresh, frozen, sterilized, and evaporated milk.

A specific problem beyond nutrient and flavor changes, in great need of solution, is to find how to dehydrate milk in a manner that permits rapid and satisfactory rehydration, free from visual defects and "chalkiness." This problem merits increased attention by scientists highly trained in colloid chemistry, working in liaison with others who are familiar with the biological and engineering aspects of the problem.

Emergency Testing

Simple, rapid clinical tests that could be used by technicians and nursing personnel should be developed for use in disaster areas, to gauge the status of emergency patients and thus facilitate their proper immediate care and establish priority of assignment to professional medical personnel. It is impossible for physicians in a given area to reach, examine, and diagnose patients rapidly enough to permit efficient care. Life and death decisions must be made quickly, and there now is no basis upon which to act with sufficient rapidity and accuracy.

Antibiotics

Intensive and prolonged use of antibiotics and sulfa drugs can have a marked effect, either favorably or unfavorably, upon nutritional requirements. These relationships should be studied as a guide in practical situations and as a means of discovering the basic relationships that underlie the observed effects. Furthermore, in the event of biological warfare or tropical warfare, this area of subject matter is likely to have first-rate importance.

Nutrition Surveys

Long-continued stress upon food resources would greatly increase the need for conducting and interpreting systematic nutrition surveys in diverse parts of the world. The requisite techniques, personnel, and plans should be developed, and initial surveys should be made to provide a reliable background for appraising trends in nutritional status.

Reference Data

Reference data pertaining to emergency care should be assembled, distributed, and used as a basis for training in each local and larger area. Broad and general plans can be developed on a national or international scale, but such plans alone will not suffice. Food resources, service facilities, stocked supplies, procedures, reserve transportation, and personnel will vary greatly from one community to another, so the available resources cannot be used efficiently unless the requisite data are properly assembled, organized, and distributed to responsible personnel in advance, on a community basis. Furthermore, there is the possibility that major fractions of entire communities may be rendered nonavailable for service, in a matter of seconds.

Conclusion

It is recognized that much work is under way relative to the topics outlined above, but there is urgent need for extending current activities in the directions indicated. On the more comprehensive and more urgent problems, additional groups should be organized to complement work already initiated.

It is respectfully suggested, also, that specific provision be made for coordination of food and nutrition research, including the independent universities and colleges, government agencies, and fund-granting agencies, to provide the greatest possible efficiency in the placement of funds and in the correlation of progress by independent groups working toward common objectives.

Other Papers on Conference

In addition to the papers from pages 607 to 643 other material on nutrition and emergency feeding problems, presented at the London Food Conference, will be published in subsequent issues of the *Public Health Reports*. Among these are "Special Feeding Problems in an Emergency," by Dr. Roy E. Butler, "Dietary Standards in the United States," by Dr. L. A. Maynard, and "Family Food Consumption Studies," by Dr. C. M. Coons.

Nutrition Lessons of the Berlin Blockade

By H. E. MAGEE, D.Sc., M.B.

The blockade of Berlin, begun toward the end of June 1948 and continuing until May 1949, has afforded lessons in nutrition that should be useful if a similar situation were to arise.

About 3 months after the blockade began, physicians from the Ministry of Health went to Berlin to examine the food and nutritional situation and to advise the occupation authorities on the feeding of the people in the Western Sectors. Systematic observations were continued during and after the blockade.

Studies were made of the food being brought into the city by airlift, the rationing of the foods, and the mechanics of the airlift, and samples of the population were medically examined from time to time. People were also inspected in factories, on the streets, in hospitals, and elsewhere. The advice given at the time was based on the findings of these studies and observations.

For all practical purposes the people of Western Berlin were dependent on the airlift for all their necessities. There was some smuggling from the Russian Sector and Zone, but this was quite small and could be ignored. The potatoes, vegetables, and fruit grown on the outskirts of the Western Sectors were evaluated on an energy basis and included in the rations. Besides food, the other necessities included the raw materials for industry, fuel, clothing, and medical supplies. Had the occasion arisen for a clear choice between food and any or all of the other imports, first place would, of course, have

been given to food. No such decision was called for and the airlift was able to bring into the city reasonable amounts of all these necessities.

Capacity of Airlift

The big question posed by the blockade was whether there was enough suitable food and the planes to carry it to Berlin. As events transpired the airlift was strained to its utmost capacity, and the amounts of suitable foods available were often far from abundant. Because of these two limitations the airlift just about succeeded in providing sufficient food to keep the population "ticking over." Towards the end of the blockade with summer approaching, it was possible to do some stockpiling and to allow for small expansion of industry; but for the whole time the tempo of life of the citizen was well below that of a normal healthy community.

Foods Carried

The dominant aim was, of course, to transport to the city the maximum nutritive value in the minimum of space and weight. Fortunately, the air forces had had much experience, especially in eastern theaters of war, of transporting food and other needs to armies in the field. In the Berlin airlift maximum use was made of dehydrated and dry foods. The potatoes had most of their 80 percent of water removed, vegetables and fruits most of their 90 percent, with little or no detriment to their nutritive values. Sugar and fats are almost water-free; flour with its 13 percent of water, and oatmeal, macaroni, and other cereal products, and legumes containing 6 to 9 percent of water required no further treatment. Coal and oil for fuel occupied a larger place in the airlift than food. For the first 9 months coal averaged about 2,200 tons and food about 1,140 tons daily. Calculations showed that it would have been more economi-

Dr. Magee, senior medical officer (nutrition) of the Ministry of Health, London, as adviser on food and nutrition to the British Control Commission, was in Berlin during the blockade. He presented this report before the scientific section of the Combined Conference on Administrative and Scientific Aspects of Food in Civil Defense, meeting at Church House, Westminster, December 4, 1951.

cal to fly in hard biscuits, or even bread, instead of flour plus the coal required for baking it, but this scheme was rejected because of the risk of losses from stale bread and because it was considered important for morale that the Berlin bakeries should be kept going.

Another way of economizing bulk and weight is to provide as much energy as possible in the form of fat, since fat contains more energy per unit weight or volume than any other food. On our arrival in Berlin less than 20 percent of the 1,600 calories daily of the ordinary consumer (group III in the table) was contributed by fat. We arranged for the proportion to be increased to almost 30 percent of the calories. Insufficient supplies prevented any further increase. In a similar emergency fats might be increased up to 50 percent of the total calories, but such a high proportion of fat could probably not be tolerated for more than 2 or 3 months.

Little use was made of dried meat, and when it was issued it was far from popular. Canned meat and fish have the great advantage that they do not require cooking and so save fuel, but they get monotonous after a period and their weight is a disadvantage. Dried eggs were much appreciated. They can be packed in paper containers, and, mainly because of their low water content, they contain about double the energy of the same quantity of canned meat. The small ration of cheese which we were able to introduce in November was

very much appreciated and so was bacon when it was available. In a similar situation more cheese, bacon, and ham for flavoring would make possible much more use of dried eggs, and transport would be economized.

Dried milk, whole or separated, is very economical on transport since it contains only about 4 percent of water. We wanted a ration of milk for everyone in Berlin, but this was not possible and it was therefore not given to anyone over 9 years of age. Dried fruit and jams were not plentiful at the time, but some were issued in place of equivalent amounts of cereal foods. They were always well received. They would have a useful place in a like emergency.

Pattern of Diet

The Berlin diet was austere, as can be seen from the table, and only the compelling force of hunger and the fear of political oppression would, I believe, make any civilized community continue to eat a similar diet for as long as the Berliners did. Austerity was no new thing to them; they had, in fact, been accustomed to hard times for more than 3½ years. Communities not so trained might react much less satisfactorily than the docile Berliners to sudden imposition of so monotonous a diet.

The average energy intake before our arrival was about 1,800 calories; it was then increased to 2,000 calories per head daily. Fortunately, the winter of 1948-49 was mild, and because

Original food rations for Berlin in grams daily and changes adopted (in parentheses) Nov. 1, 1948

Groups	Bread	Potatoes ¹	Cereals	Meat ²	Fat	Sugar	Cheese	Milk (liter)	Calories

¹ Includes vegetables. ² Includes fish, bacon, ham, and dried eggs. ³ Limited to 4 percent of population. ⁴ Expectant mothers placed in group II from fifth month until end of pregnancy and given 500 cc. milk from 4 months before until 4 months after labor.

of lack of lighting, people spent most of the hours of darkness in bed. There were fairly general increases in weight after the increase in the rations, but this could be attributed also in great measure to the enforced rest and to the mild weather. Signs of undernutrition which were self-evident, especially in boys and adolescents, in men of large physique, and in

parents of large families, declined in severity and frequency after the rations were increased. Our clinical and other observations convinced us that 2,000 calories a day was a bare minimum and sufficed merely to keep the population at a subsistence level. In addition, the proportion of women, children, and aged was unusually high in Berlin. With all forms of

(Continued on page 625)

Nutritional status of individuals seen in Berlin in November 1948, March and October 1949, expressed as percentages

Group	Number	Dates of examination	Good	Fair	Poor
Men	105	November 1948	61.0	29.5	9.5
		March 1949	75.2	21.0	3.8
		October 1949	84.8	14.3	1.0
Women	52	November 1948	80.8	17.3	2.0
		March 1949	86.6	13.5	
		October 1949	92.3	5.8	2.0
Boys	98	November 1948	42.9	46.0	11.2
		March 1949	82.7	16.3	1.0
		October 1949	89.8	8.2	2.0
Girls	111	November 1948	64.9	27.0	8.1
		March 1949	79.3	19.8	.9
		October 1949	91.9	7.2	.9

NOTE: This table was included in the paper, "The Food and Nutritional Situation in Berlin During the Blockade and After," by Dr. W. T. C. Berry, Dr. P. J. Cowin, and Dr. H. E. Magee, published in the Monthly

Bulletin of the Ministry of Health and the Public Health Laboratory Service, July and August 1951. The paper was discussed in conjunction with Dr. Magee's presentation.

The nutritional status of Berliners, shown in the above table, was assessed by paying particular attention to pallor, tired expression, lethargy, poor posture, diminished muscular tone and development, lack of luster of the hair, and diminished fat. By assessing these criteria and the all-around general appearance, the subjects were classified as in "good," "fair," or "poor" nutritional condition. In November 1948, many of the sample subjects showed all or most of the stigmata. There was slight improvement in January and in March 1949, but in October 1949, the manifestations had almost entirely disappeared, except in a few cases. The improvement in all groups from November 1948 to October 1949 was striking, but specially so for the boys. Only 43 percent of the boys attained the "good" grade in the No-

vember 1948 examination, but 82 percent were in that grade in March, and 90 percent in October 1949. The least improvement was shown by the men, and more often than not men of large stature showed more ill effects. Probably the rations were too small for the bigger men, and an appreciable number of men were still suffering from the effects of privation in Russian camps or from the effects of war service. The women were relatively much better nourished at all three examinations. The status of Berlin children in October 1949 was only a little less satisfactory than that of English school children during the same year. Of 3,181 English children examined, 93.8 percent were in "good" nutritional condition, 5.5 percent, "fair," and 0.7 percent, "poor."

museular activity reduced to a minimum, 2,000 calories daily would probably just suffice for a community of average composition similarly placed, but morale would suffer and discontent would probably develop.

From a strictly health, apart from the political, standpoint, there can be no doubt of the wisdom of those in authority in Berlin of keeping industry going as far as possible. The Berlin dietary, however, should have been on the average about 300 calories more per head daily. Plans were made for an increase of about 150 calories a day, and they would have been put into operation during May 1949 if the blockade had continued. For a community of average composition expected to keep its main industries going on a moderate level, an average diet of not less than 2,300 calories should be provided.

If, however, full employment were the aim, then the target would have to be considerably higher than 2,300 calories. The diet should also be made less austere than the Berlin one, for example, by increasing the rations of meat (meat, bacon, fish, and eggs) and cheese, and by making more use of dried fruits, jam, and cereals of low moisture content, such as rice. Everyone should have a ration of not less than 9 ounces of milk in dried form and adolescents and children, not less than 18 ounces. Whole milk is better than separated milk because of its higher energy value.

Vitamins

Provided the flour supplied is of not less than 80 percent extraction, there would be no need to take special precautions about the vitamin B complex. In Berlin we found no clinical evidence of deficiency of any of the B factors. The flour was of 85 percent extraction or more, and on our recommendation it was fortified with calcium, as in the United Kingdom.

We reckoned that the average vitamin C intake in Berlin was probably 5-10 mg. daily; the dried potatoes and vegetables contained appreciable amounts. At no time were we able to find any evidence of scurvy, even after extensive search. Nevertheless, a ration of 150 mg. ascorbic acid weekly was made available early in 1949. In similar circumstances there would

be no compelling need to supply a ration of ascorbic acid during the first 3 months of the blockade unless supplies were readily available. Concentrated fruit juices are obviously ruled out because of their bulk.

We did not find any evidence of vitamin A deficiency and only after prolonged search did we find a few cases of mild rickets in children. The Germans are accustomed to use "Stoss-therapie" as a prophylactic measure, and it may be that children born before or early in the blockade were protected in this way. Supplies of concentrates of these vitamins were meager when we arrived in Berlin, and a ration of cod liver oil was arranged for children up to the sixth year, but this was not found to be possible for pregnant women. In a like emergency, pregnant and lactating women and children up to 5 or 6 years should have a ration of cod liver oil or similar fish liver oil.

Rations

The original Berlin ration scale was a relief of the Kommandatura days. It can be seen from the table that the energy content of the rations decreased from 1,786 for children 0-1 year, to 1,559 calories at 14 years. We tried to get this absurd scale altered to bring it into conformity with physiological requirements, and to get a special ration for adolescents, but for several reasons this was not done. In any similar situation comprehensive rationing of all foods would, of course, have to be introduced, and the plan of rationing would have to take strict account of the needs of every section of the population which might, for example, be classified into the categories suggested in the report of the Committee on Nutrition of the British Medical Association, 1950. The division into categories should be made as fine as possible so as to minimize the risk of gross inequalities in rations in relation to needs. Those of large physique, both adolescents and men, with large energy requirements would still remain a problem. If the blockade were to last for only 2 months or so, it would probably not be necessary to make any special provisions for them, but if it were to extend beyond this time then special arrangements should be made. In a small community this should not present in-

superable difficulties. In Berlin the large man of 6 feet or more, with emaciated appearance and vacant expression, who could not get enough to eat was one of the most pathetic sights.

Condiments

Table salt is most important; it is indeed indispensable and should be brought into the beleaguered city without delay. Pepper, chilies, mustard, and other spices should also be brought in. They take up little space and are important in improving the palatability of otherwise dull and unappetizing food. Carriage of salt to Berlin presented difficult problems. Some salt always manages to escape from the containers, and because of its hygroscopic properties it fouls the controls of land planes. Eventually, it was carried in seaplanes which flew from Hamburg to one of Berlin's lakes. Imports of alcohol should be restricted to spirits intended for the sick, but for the maintenance of morale the controlling authority might find it expedient to provide a ration for adults. In Berlin one of the breweries was kept going at a much reduced level of output, the object being, I believe,

more to keep the brewery in working order than to supply any particular need. The issue was on a very small scale and went to clubs and to a few German restaurants which were able to open toward the end of the blockade. Tea and coffee should be provided in generous amounts; they occupy little space. The coffee issued to the Berlin population probably played an important part in the maintenance of morale.

Packing of Food

Flour formed the greatest bulk of the Berliners' food. It was carried in sacks which packed easily into the aircraft. Dried potatoes, vegetables and cereals, and dried eggs were put up in ration units in small rectangular cases made of strong paper. They were packed in cardboard boxes, which packed easily into the aircraft and were convenient to handle. Canned meats and fish were packed together in cardboard boxes; these fitted easily into the plane and were not difficult to handle, but the weight of the metal was a great disadvantage. The only alternative, dried meat, had also a serious drawback; people soon got tired of it.

Reconditioning Salvaged Food in Britain, 1943-45

In 1943 salvaged canned goods were cleaned under makeshift conditions (above). The average output was 1,700 cans per man-week. The other photograph is a view of a workroom in a specially designed reconditioning depot in 1945.

The depot was capable of sorting, reconditioning, and repacking 600,000 cans per 48-hour working week with a staff of 150, mainly women. The average output was 4,000 cans per man-week.

Food Sanitation in Civil Defense

During the scientific section meetings of the Combined Conference on Administrative and Scientific Aspects of Food in Civil Defense held in England last winter (see pages 607 to 626), sanitation considerations were explored in some detail. The five papers presented here were selected as being of particular interest and value to public health and civil defense workers in the United States.

Examination and Salvaging Of Food Supplies

By WINTON B. RANKIN, M.S.

The methods the Food and Drug Administration, Federal Security Agency, employs to determine whether foods are suitable for consumption after damage by blast, fire, or water, or contamination with radioactive materials are described here.

Radiation Hazards to Foods

A nuclear explosion may contaminate food with unfissioned materials, with fission products resulting from the explosion, or by inducing radioactivity in materials located near the explosion.

Careful analysis of available data indicates that there will be no significant induced radioactivity in foods which are far enough away from the center of an explosion to escape destruction. The slight radioactivity which may be induced in a stock located in a well-protected shelter near ground zero will be predominately short-lived. It will be virtually dissipated by the time salvage crews are able to enter the area for clean-up operations.

Thus, we are concerned only with fission products (beta-gamma emitters) and with unfis-

sioned bomb material (an alpha emitter). These contaminants will be deposited as a fine dust or a mist upon containers or directly upon food or drink itself. They penetrate in the same manner as nonradioactive dust or mist. Materials in undamaged, well-closed warehouses, rooms, or packages will not be contaminated. Soluble radioactive elements dissolve in water or liquids, and thus may be carried in water through porous containers.

The contaminants are removed by washing waterproof containers with a detergent and by dusting or brushing other containers. Surface layers of bags, cases, or bulk food showing heavy contamination may be removed and impounded to permit decay of radioactive isotopes. Later analysis in a laboratory will show whether the contents are safe for consumption. Permeable containers, such as cloth bags and porous paper wrappers, may permit radioactive dust or mist to seep through and contaminate the food itself. Likewise, exposed food may be seriously contaminated. In such cases, surface contamination must be removed as completely as possible, and the field test described below must be applied to determine whether the food is safe.

Food and water which contain the following amounts of beta-gamma contamination may be consumed if other supplies are not available. (Emergency tolerances are those announced by the Civil Defense Administration and the Atomic Energy Commission.)

Mr. Rankin is assistant director of field operations, Food and Drug Administration, Federal Security Agency.

Time food or water is to be consumed	Acceptable beta-gamma activity in disintegrations per minute per cc.
10 days-----	200,000
30 days-----	70,000

Plymouth Food Office Incident

In October of 1939 Plymouth's old Guildhall was used as the local food office (upper photograph). In June of 1943 the Guildhall was bombed during a raid (center picture). The food office was reorganized and at work in a marquee 48 hours after the raid (lower photograph).

The consumption of these quantities of radioactivity during the periods indicated will cause less damage than withholding essential supplies from a stricken community.

A portable Geiger-Mueller survey meter will detect readily these tolerance levels of radioactivity.

Each survey team is supplied with a reference standard giving the equivalent of 200,000 beta-gamma disintegrations per minute per cc. The team places a sample of the contaminated material in a container of the same size as that holding the reference standard and compares the activities of the sample with the standard.

Samples with greater activity than the standard are not safe for use. Samples with less activity are suitable for use for a 10-day period. Samples with less than one-third the radiation given off by the standard are suitable for use for a 30-day period.

While this procedure is reasonably accurate for thin layers of liquids, research is required to confirm its reliability with solid or semisolid samples.

No effort will be made in the field to determine whether contaminated food may be used longer than 30 days. Peacetime tolerances for radioactivity are so small that an accurate measurement of them should be made with a conventional scaler.

Emergency tolerances for permissible alpha activity in drinking water or food also have been calculated. These are:

<i>Time food or water is to be consumed</i>	<i>Acceptable alpha activity in disintegrations per minute per cc.</i>
10 days-----	11,000
30 days-----	3,700

We do not have a portable field instrument which will measure satisfactorily these levels of contamination with alpha emitters. Possibly a portable scintillation counter would be suitable. Such an instrument is needed.

Except where a bomb fails to fission properly, the amount of beta-gamma radiation resulting from fission products is so much greater for the first month than the amount of alpha contamination from unfissioned material that we can forego direct measurement of alpha radiation during that period. If the beta-gamma

contamination is less than its tolerance value, the alpha contamination is below its tolerance value.

These emergency tolerance values should not be applied beyond 30 days.

Crops which grow on soil heavily contaminated with radioactive elements, and seafood which grows in radioactive waters, may take up significant amounts of radioactivity. This hazard will not develop suddenly. After the acute emergency following a nuclear explosion, perhaps after 30 days or more, food coming from radioactive soils or waters should be examined in the laboratory to determine whether they contain more than the peacetime tolerance for radioactivity.

Blast and Fire Hazards to Foods

The technical problems associated with food salvage following blast and fire damage of war are essentially the same problems which accompany major blast and fire disasters in peacetime. Many major fires are fought with impure water from rivers or harbors; thus, we also must consider water damage.

Perishable products probably will deteriorate beyond salvage if located near a major disaster. If salvable, they should be cleaned as thoroughly as possible and cooked promptly to destroy harmful bacteria.

Semiperishable materials, such as dried fruits, deteriorate rapidly when they are mois-

Salvage of typical foods

Kind of food or package	Possible salvage procedure in case of—		
	Contamination with radioactivity	Blast and fire damage	Water damage (pollution)
Perishable: Fresh fruits and vegetables, fish, poultry.	Remove outside portions of lot containing most radioactivity. If remaining contamination is less than emergency tolerance, release interior portions. Washing of fruits and vegetables may be of value.	Look for contamination with poisons. If carriers of pathogens are present sterilize before using.	Wash to remove surface contamination. Cook to kill bacteria.
Nonperishable: Dried fruits and vegetables; flour and grains; bulk sugar stocks.	As above (except that washing is not feasible).	As above-----	Prompt sterilization and use of fruits and vegetables. Remove flour and grain which is not caked. Cook before using. Re-refine sugar.
Cardboard and paper containers.	As for flour, above. Removal of dust by brushing. Remove outer wrappers.	As above-----	If salvage attempted, sterilize food in water-damaged containers before it is consumed.
Sugar (bulk stocks)---	As for flour, above-----	As above-----	Re-refine.
Canned goods: Hermetically sealed cans.	Wash outside of container with detergent, or remove radioactivity by brushing. Interior portions of stacks may be relatively free of radioactivity.	Look for and destroy cans with ruptured seams or closures. Remove abnormal cans. Look for spoilage from thermophilic organisms.	Sterilize surfaces of cans. Watch for pinholing of metal. Use damaged stocks promptly.
Containers with screw caps, friction type lids, etc.	As above. Test contents before releasing for use.	As above-----	Difficult to remove contamination from beneath or around closure. Sterilize foods before using.

Food Salvage Operations in England, 1944

At Streatham on the night of June 16, 1944, a fly bomb completely demolished a building containing 650 tons of foodstuffs. Salvage operations, completed in 6 weeks, resulted in recovery of 636 tons.

On the night of August 4, 1944, a fly bomb attack at Dudins Wharf, Bermondsey, resulted in a direct hit on a building containing 9,000 tons of cereals and oilseeds. Fires resulting from a burst gas main raged for 4 days. Salvage operations lasted 3 months, resulting in the recovery and utilization of 8,000 tons. The picture at top shows a general view of the site during salvage operations. The photograph below illustrates the problem of fly infestation which hampered salvage operations.

tened. If molding or decomposition has not set in when salvage is possible, damaged containers should be earmarked for prompt consumption; sterilization is required if the foods are polluted.

The surface of flour cakes when it is moistened. Some water-damaged flour may be salvaged by removing the uncaked material from inside bags or bins. Bulk lots of grains swell and form a solid mass; large quantities which have not been wet may be salvaged from inside elevators which have been subjected to heavy water damage.

Any food may be exposed to poisonous materials scattered about the storage area by blast. Often insecticides and foods are stored in the same warehouses, leading to the possibility of mass poisoning from the scattering of the poisons over foods.

Hermetically sealed cans may be ruptured by blast: they should be examined carefully for sprung seams which will permit spoilage. Decomposition resulting from damaged cans should be apparent in 7 to 10 days; adequate salvage will then be possible. Cold weather may retard the appearance of swells or leakers.

Hermetically sealed cans which are heated and cool slowly may develop spoilage from

thermophilic organisms. The spoilage may not be apparent from the outside of the container. Such lots should be examined in a suitable laboratory.

Hermetically sealed cans exposed to pollution from water or other sources should be sterilized before release to the public. The cans may rust and develop pinholes before salvage.

If not, they should be used promptly after release because of the danger of pinholing.

Glass jars with screw caps, cans with friction-top lids, and similar containers without hermetic seals, and hermetically sealed jars with anchor- or crown-type closures are difficult to salvage following contamination with polluted water or other filth. Pathogenic bacteria lodge under the caps or beneath rubber gaskets and may be introduced into the food when the container is opened. Foods in such containers should be sterilized before consumption.

Foods in cardboard cartons, paper wrappers, and similar containers may be contaminated with toxic bacteria or poisons through breaks in the packages. Water damage to this type of package calls for adequate sterilization of the contents before use if salvage is possible.

If transportation and manufacturing facilities are available, large stocks of some foods, sugar for example, may be salvaged by re-refining even though they are heavily contaminated.

The table gives a summary of some of the salvage methods suggested.

The most pressing problems which remain unsolved are: how to measure alpha contamination in the field with portable equipment; and how to cope effectively with sabotage of the food supply.

A Safe Water Supply In Civil Disaster

By **GORDON E. McCALLUM, B.S.**
WILLIAM E. HOLY, M.S.
HARVEY LUDWIG, M.S.

Water, although not a food, is essential to life and therefore a necessary component of man's diet. Furthermore, water is important in the preparation, processing, and distribution of many foods. Any comprehensive study of the food aspects of civil defense, therefore, should consider those changes in the quality and quantity of the public water supply which are likely to occur in a civil defense emergency. Civil defense officials will be particularly con-

cerned inasmuch as they may be faced with the problem of providing an emergency supply of water in the event of failure or serious contamination of the public supply.

Contamination of Public Water Supply

While similar in many respects water differs from other utility services, such as gas and electricity, because of its vital public health significance. Possible contamination of the public water supply is one of the greatest hazards to the health of the community. Although it is well recognized that water readily transports organisms causing such diseases as typhoid, cholera, and dysentery, its safety is seldom questioned by the citizen of the modern community. This record of safety and achieved assurance did not just happen. It is the result of more than 100 years of effort, study, surveillance, and careful sanitary control. Continuous research has brought about marked improvements in water works equipment and materials as well as in their operation and use. Furthermore, these resources are now under the control of more competent personnel. However, these safeguards in the form of modern collection and treatment of sewage and purification and protection of public water supplies are man made. Consequently, they can be suddenly destroyed, particularly so by man himself.

Wartime attacks upon civilian populations would break down many of these safeguards and at the same time intensify public health hazards. In addition there would be new dangers arising from possible use of special weapons of war. Scientific research on biological, chemical, and radiological substances indicates that some of these agents could contaminate public water supplies. Such contamination might occur as a direct or incidental result of attack, or by sabotage.

Mr. McCallum is chief of health emergency planning of the Office of the Surgeon General, and Mr. Holy is water supply consultant of the Division of Sanitation, Public Health Service. Mr. Ludwig is sanitary engineer consultant of the Federal Civil Defense Administration.

Sewage

Sewage or organic contamination is most serious when it occurs within the water distribution system. Contamination in distribution systems may occur in normal times when pressures are reduced as a result of broken mains, heavy drafts for fire fighting, valve closures, and supply failures. Contamination may result from cross connections, backflow through faulty plumbing fixtures, and inadequate precautions taken during construction or repair operations. Incidences of such contamination will be greatly increased should the system be severely damaged.

Special Warfare Agents

Although the feasibility and effects of deliberate contamination of water is controversial, the vulnerability of the water works system to contamination by biological, chemical, and radiological warfare agents should be carefully studied. Water works structures which are most vital include unprotected transmission mains, water service lines connected to these mains, valve chambers, booster pumping stations, chlorination stations, and open reservoirs and other locations of water storage.

Precautions for the protection of these structures include automatic alarms at hidden work locations, backflow preventers, and automatic signal devices to give an appropriate alarm whenever an abnormal flow condition exists.

An automatic signal device to detect changes in chlorine residual might be useful in certain critical locations. Increased surveillance and intensified alertness are indicated.

Biological Warfare Agents

Biological warfare against human beings may be defined as the deliberate use of disease-producing organisms or their products to cause illness or death in a target population. BW agents may include bacteria, bacterial toxins, fungi, rickettsiae, viruses, and protozoa. It is generally conceded that the public water supply could be deliberately contaminated by certain of these agents.

It may be assumed that small quantities of BW agents may contaminate portions of a water supply system. Evidence that low doses of bio-

logical agents may be dangerous is suggested in the work of Kehr and Butterfield (1).

The agents of particular concern may be those not commonly found in water. As a result our normal public health safeguards might not be effective against them. We should not, however, rule out the possible use of common intestinal pathogens which by clever manipulations might be made to penetrate our water works defenses. The use of several agents simultaneously would complicate early attempts at detection and might make diagnosis of resulting diseases difficult.

Chemical Warfare Agents

The "war gases" may be defined as chemical agents used to create vapors, fogs, or aerosols that are poisonous by inhalation or, in the case of persistent agents, by contact and inhalation. Of the former, the mustard and nerve gases appear to be the most formidable.

Most effective poisons of the inhalation type are chemically unstable or otherwise not suitable for use as a water poison. However, some contamination of water might occur incidental to the tactical military use of these agents.

Pertinent details about chemical warfare agents, including procedures for their detection and control, are being assembled in a forthcoming Federal Civil Defense Administration manual on water utilities in disaster relief operations.

Radiological Warfare Agents

Deliberate attempts to contaminate water supplies with radiological agents are not considered likely at present. Other methods of contamination would appear more feasible. Contamination of reservoirs, however, and other open bodies of water might occur as an incidental result of an atomic bomb burst, particularly from surface or subsurface detonations.

Allowable concentrations of radiation in water for short periods during emergencies have been announced by, and are available from, the Federal Civil Defense Administration.

Detection of Contamination

Contamination in water supplies is routinely detected by the use of chemical, physical, and

bacteriological examinations well known to water works and public health workers. The primary object has been the detection of contamination by sewage or human intestinal discharges. The standard bacteriological test for coliform organisms, which indicates intestinal contaminants, is an important procedure employed by health authorities to judge the sanitary quality of a water supply. One of the limitations of such tests is the time—24–48 hours—which elapses before the results are known and control measures instituted. In the past decade many water works in the United States have placed increased reliance on the chlorine residual determinations, which can be quickly accomplished, thus permitting prompt plant adjustments to insure the maintenance of desired residuals. Experience with any given water under normal conditions indicates the amount of chlorine needed.

The problem of detection in times of disaster may involve the determination of increase in sewage contamination, as well as possible biological, chemical, and radiological warfare agents. In the case of sewage contamination, the intensification of the control procedures already used is indicated. Continued study and adoption of new procedures as they are developed will be necessary to deal adequately with BW, CW, and RW agents.

Improved Bacteriological Techniques

The standard bacteriological examinations are, as previously noted, rather time consuming. Recognition of this shortcoming no doubt hastened further development of a promising device known as the "membrane filter" (2). This filter consists of a paperlike cellulose ester membrane containing a high concentration of uniformly spaced pores of relatively constant diameter. The pore diameter may be made sufficiently small to remove practically all of the bacteria in the water being filtered. An interesting feature of this filter is the high flow rate under relatively low hydraulic head, a property attributed to the fact that the pore is shaped like a funnel with the small opening at the inlet surface. No attempt is made to remove the bacteria captured by the filter, but, instead, they are cultured in place. This is done by placing the filter, after use, on an ab-

sorbent pad containing culture medium which, when wetted, will diffuse upward through the pores to form a satisfactory growth substrate for the organisms.

This technique makes possible a substantial reduction in the time, labor, and space required for conducting bacteriological examinations. Moreover, the results are precise and the method may be readily adapted to field use. These advantages indicate this device to be especially valuable for prompt detection of biological contamination.

Research work with the membrane filter is being continued, including studies to adapt it for rapidly detecting BW agents as well as coliform and other intestinal organisms. Its usefulness in recovering pathogenic bacteria and fungi may be increased by the development of more highly selective nutrient media. It is unlikely, however, that a single culture medium will be found to be sufficiently selective for all organisms.

Detecting Radioactivity

The levels of radioactivity previously mentioned may be measured with presently available portable monitoring instruments. Detailed data on this subject is available in a recent bulletin, "Use of Commercially Available Portable Survey Meters for Emergency Fission Product Monitoring of Water Supplies, August 3, 1951," published by the University of Rochester, New York, together with the United States Atomic Energy Commission.

Decontamination Measures

Many water works officials attempt to carry chlorine residuals throughout as much of the system as possible. Breakpoint chlorination, a process by which all organic matter is quickly oxidized by high chlorine concentration, has been increasingly used during the past 10 years. It represents a significant improvement in disinfection in that it provides a residual of free chlorine throughout the distribution system. As compared with the usual combined chlorine residual, free chlorine is an extremely effective disinfectant. For these reasons this type of disinfection should offer greater protection against biological agents than conventional or marginal chlorination which is frequently employed.

Inactivation of Biological Agents

Standard water purification procedures, including presedimentation, chemical coagulation and settling, adsorption on activated carbon, filtration and pH control, offer satisfactory protection against many bacteria and fungi. The unsatisfactory performance of these treatment methods in the removal of certain viruses has been suggested in recent work on infections hepatitis and anterior poliomyelitis. Disinfection with chlorine in high concentration, however, does appear to be effective against these viruses.

It is hoped that additional safeguards to supplement chlorination may be found in studies of new water disinfectants.

Under emergency conditions routine treatment and disinfection may of course be supplemented by boiling.

The decontamination of a water supply system following a suspected or known BW attack will not differ materially from the procedure normally used for accidentally contaminated systems or those being placed in operation for the first time. This procedure should include a thorough flushing of all parts of the system, including household service connections, and disinfection with a strong chlorine solution.

Removal of Radioactive Materials

Removal of radioactive materials from water is involved and uncertain. Conventional treatment processes are not completely effective in removing all possible contaminants. The removal of any chemical substance, radioactive or not, is dependent upon its physical and chemical nature. A common radioactive characteristic does not imply a common removal tendency when subjected to the various treatment processes. If radioactive materials were to be deposited in a stream or watershed, several natural agencies would be effective in reducing the amount which might finally reach the treatment plant. Among these agencies, the most significant are:

1. Natural decay which is continuous, unaffected by the chemical or physical state of the isotope, and in most fission products quite rapid, decreasing with time.

2. Dilution of the radioactive materials with

the water reducing the concentration significantly.

3. Adsorption of the radioactive substances on suspended turbidity particles or other matter with subsequent sedimentation, and adsorption on bottoms and banks of streams and reservoirs.

Research is under way to determine the efficiency of the several conventional water treatment processes in removing radioactive isotopes. The procedures that can be employed by a rapid sand filter plant to improve its efficiency for removing radioactive substances are:

1. Increased dosage of coagulant to produce most effective floc formation.

2. Maintenance of the pH of coagulation as high as possible (a pH of 10 or 11 being preferable) by the addition of excess lime or soda ash.

3. Addition of coagulant aids such as activated silica, bentonite or other clays, and activated carbon.

The general function of these steps is to improve coagulation and thus increase adsorption by agglomeration. Whether or not safe water is produced will depend upon initial concentration of contaminants in the water, their susceptibility to removal, and the efficiency of the treatment processes. In any event, the finished water should be assayed for radioactivity. If the amount exceeds accepted tolerance limits, it should of course not be used.

Emergency Water Supply

Provisions for emergency water rations should be made in the event the public supply is interrupted or so contaminated that it may not be safe. Instructions should be issued to home owners regarding the storage, home decontamination, and conservation of water.

Careful planning will be necessary to assure that an emergency water supply can be made available to institutions, refuge centers, hospitals, and first aid stations. Various emergency sources may be employed, for example, water contained in local covered storage reservoirs which may be used without special treatment, and nonpotable or contaminated supplies which are first made safe by filtration, disinfection, or both. Equipment needed will include mobile water treatment, filtration, chlorination

and pumping units, hose lines, and tank trucks. Pre-disaster preparations should comprise an inventory of available trucks, including water sprinkling, milk, and petroleum products trucks, as well as plans for cleaning them.

Conclusion

In the event of enemy attack upon a community, its public water works system may be seriously damaged and the water supply subjected to gross contamination by sewage or special warfare agents. Also, in the immediate period following disaster, huge drafts may be placed upon the system to supply water for fire fighting. This, too, introduces additional hazards to the safety of the supply. Under these circumstances there may be a shortage of water over a considerable period, and water that is available may require special treatment. These effects can be minimized, however, by proper planning and preparation.

Milk Control Planning For Civil Disaster

By GORDON E. McCALLUM, C.E.,
JOHN D. FAULKNER, M.S.P.H.E.

In event of attack on major population centers, milk pasteurization plants and cold storage facilities, as well as transportation and utility services, are likely to be destroyed or their operations disrupted. Following such disaster, immediate measures must be taken to conserve and protect the target city's milk supply; to provide for its adequate processing for the

health protection of consumers; and to insure milk distribution to those immediately requiring it.

Considerable attention has been paid in the United States in recent months to the development of plans by Federal (1, 2), State, and municipal governments, and by industry (3) for dealing with milk supply problems likely to arise in event of large-scale civil disaster.

In the United States, the milk production and processing industries are decentralized over a vast geographic area, and all of our major cities have developed their own milksheds from which they obtain a large proportion of their fluid milk supply. Sanitary control of milk production and processing, as a preventive measure against transmission of milk-borne disease, is extensive. This control is exercised chiefly by State and local authorities, and not by the Federal Government. Practically all market milk sold in the United States is pasteurized, using a time-temperature combination of either 143° F. for 30 minutes or 161° F. for 15 seconds. Raw milk for pasteurization is usually transported from the dairy farm to country receiving stations, and thence to the pasteurization or processing plant, or to the plant direct, by automotive equipment. Although some milk for pasteurization is shipped to distant markets by rail, refrigerated or insulated automotive tank trucks are customarily used to haul raw milk great distances.

Diversion of Fluid Milk Supply

As most dairy farm producers of milk for pasteurization are not located in the immediate vicinity of our large urban centers, it is unlikely that many would be damaged or seriously affected by enemy air attack on a given target city. Conversely, many milk processing plants of an attacked city might be destroyed, seriously damaged, or otherwise made inoperative. Therefore, it is necessary to plan for emergency

Mr. McCallum is chief of health emergency planning of the Office of the Surgeon General, and Mr. Faulkner is chief of the milk and food branch of the Division of Sanitation, Public Health Service.

diversion of the city's raw milk supply to previously designated pasteurization plants, other milk processing plants, or to cold storage facilities in outlying areas and nearby communities. Routine automotive transportation of milk from dairy farms to receiving stations and processing plants affords a high degree of flexibility in developing diversion plans.

Emergency Milk Processing Facilities

Civil defense authorities of each potential target city must develop plans in conjunction with the local milk industry for the use of specific facilities in outlying areas which can receive and pasteurize portions of the diverted supply. These facilities should be earmarked according to their maximum operative capacity on an emergency basis, and agreements obtained for their use in civil disaster. Each milk receiving station should be assigned at least three alternate emergency processing plants and, where considered necessary, each milk producer should be assigned at least three alternate receiving stations or emergency processing plants, listed in a predetermined sequence to be followed for delivery of milk if it becomes necessary to divert the supply.

The requirements of each emergency processing plant for auxiliary equipment and supplies should be carefully noted to enable the plant to pasteurize and handle a portion of the diverted supply. Arrangements for the procurement of such equipment and supplies must be included in over-all civil defense plans.

Following large-scale civil disasters in the United States, in some instances the supply of fluid milk available to the stricken area is likely to far exceed the immediate need. The disposition of this surplus milk must be anticipated and plans made for its conversion if possible into concentrated milk products. If such arrangements cannot be made, other disposition must be planned so that emergency processing and cold storage facilities will not be overtaxed.

Public Health Protection

The sanitary control of fluid milk and milk products in times of civil disaster is of the utmost importance. The possibilities for disease

transmission are multiplied many times, while routine control tends to break down or is overtaxed. From the standpoint of protection against milk-borne disease, it would be desirable to maintain existing sanitary standards for the production, processing, and handling of milk, and to intensify control procedures. However, this will not be possible in the immediate postdisaster period, and emergency standards and control procedures must be developed. In developing such emergency standards, departures from existing standards should be made only when clearly required. Every effort should be made to re-establish existing standards as soon as possible in the postdisaster period.

Immediately following the disaster, the efforts of the health department, or other milk control authorities, should be directed toward control of the pasteurized supply. All emergency milk processing facilities should be inspected as soon as possible after the disaster, and at frequent intervals thereafter, to determine compliance with minimum standards for proper operation. Inspection of producer dairies and receiving stations should be discontinued during this period, but producers should be forewarned that they must continue to comply with existing standards insofar as possible.

Bacterial examination and phosphatase tests of samples of pasteurized milk from each emergency processing plant should be made daily until operations have been stabilized, and at frequent intervals thereafter. Because of the laboratory workload involved, the assistance of industry laboratory technicians and facilities will be required. Plans should also provide for the use of laboratory facilities outside the target area. The bacterial examination of samples of raw milk from producer dairies should be discontinued during this period in order that laboratory efforts can be directed to the control of the pasteurized supply.

As a result of an attack, the emergency milk pasteurization facilities for a stricken area may be inadequate to meet immediate needs. Therefore, advance planning should provide for the issuance of instructions to emergency feeding centers, restaurants, and to the public on emergency methods for the pasteurization or steri-

lization of raw milk in the event that raw milk must be distributed.

Distribution of Emergency Milk Supplies

In civil defense planning for the distribution of foodstuffs in a disaster area, the nutritional need of special groups for milk must be given special attention. Infants, children, pregnant women, special dietary cases, and the injured will require milk in some form. Food supply plans should provide for the distribution of pasteurized milk direct from emergency processing plants to mass feeding centers, other communal kitchens, evacuation points, medical facilities, and stores. In the immediate post-disaster period it is likely that the establishment of emergency milk distribution centers will also be required. As soon as possible, however, distribution through regular retail outlets should be re-established.

Plans should provide for the use of existing milk industry automotive equipment for distribution purposes. If sufficient milk trucks are not available, other vehicles should be requisitioned and used solely for this purpose. During delivery, milk should be iced or otherwise maintained at a temperature of 50° F. or below.

In the immediate postdisaster period, pasteurized milk may have to be delivered in bulk rather than in individual containers. Special attention must be paid to the storage, handling, and serving of bulk milk to prevent contamination. Milk stored at mass feeding centers, other feeding establishments, and at emergency milk distribution stations must also be kept refrigerated.

Substitution of Concentrated Milk Products

A portion of the raw milk supply of a number of our likely target area cities is produced on distant milksheds which extend into several States. This milk is shipped both by rail and automotive tank truck to the cities concerned for pasteurization. An attack on a major transportation center, or simultaneous attacks on several large cities, could disrupt the Nation's transportation system to such an extent that a large portion of the raw milk supply of

some of these population centers would be cut off temporarily. Where this probability exists, advance planning should provide for the substitution of milk powder and canned milk until the fluid supply is restored.

Some forms of concentrated milk would also be more adaptable to utilization during the immediate postdisaster period than fluid milk, for example, canned milk required for the preparation of infant formulas. Civil defense planning should provide for the procurement and distribution of concentrated milk products to meet special needs.

Rationing

In view of the large supply of milk available for fluid consumption in the United States and the decentralized nature of our fluid milk production, it does not appear that rationing will become necessary on other than a temporary basis in the immediate postdisaster period. However, restricted distribution of concentrated milk products may be needed because of shortages resulting from transportation difficulties.

Training of Auxiliary Personnel

The training of auxiliary personnel, both for key positions of milk processing plants and for emergency milk sanitation duties, is of the utmost importance. Auxiliary personnel will be needed to supplement the staffs of emergency milk processing plants and milk control agencies and as replacements for regular employees who become disaster casualties. Milk plants should select from among their own employees alternate personnel for each key position. Such personnel should be thoroughly trained in their alternate duties so that they may take over operations if necessary. Auxiliary milk sanitation personnel and laboratory personnel should be recruited and trained by the health department or other proper milk control authority.

Auxiliary Utilities, Equipment, Supplies

The various utility services in the fringe and outlying areas of major population centers are likely to be disrupted in case of enemy attack.

For those plants located in outlying districts and dependent upon the target area for power, consideration should be given to the need for standby or auxiliary power equipment in order to maintain operations and refrigeration in emergency processing plants in case of the destruction or serious disruption of the main power supply. Alternate methods for the operation of boiler units must also be considered. In addition, if the plants selected for emergency milk processing do not have auxiliary water supplies and are dependent upon the target city supply, consideration must be given to obtaining an alternate source of water. Auxiliary water supplies should be properly protected against contamination, and should be subjected to inspection and bacteriological examination as a pre-attack readiness measure.

Additional supplies of milk bottles, other containers, chemical detergents and bactericides, spare parts, and miscellaneous materials will be required by the emergency processing plants in event of a disaster. Advance planning must provide for the procurement and distribution of such emergency supplies. Consideration should be given to the storage of normal industry stocks in warehouses outside the area of probable destruction. It will also be necessary to plan for the emergency needs of dairy farm producers and milk receiving stations, including maintenance or feedstuffs for dairy cattle.

Rehabilitation of Damaged Facilities

It is possible that only a few of the plants supplying a disaster area may be destroyed or badly damaged by an attack, and if power and water are available, only a limited portion of the supply need be diverted. In case atomic weapons were used in the attack, all undamaged and partially damaged plants should be monitored for radioactive contamination prior to resumption of operations. Advance planning should provide for rapid monitoring and decontamination of milk processing facilities.

As soon as practicable after an attack, a survey should be made of complete and partial damage to, and contamination of, milk processing plant and cold storage plant facilities in the stricken area. Civil defense aid should be provided to restore operations where it is fea-

sible to do so. Where immediate resumption of operations is not advisable, undamaged equipment and supplies should be salvaged for use in other plants.

Hazards of Warfare Agents

In general, we believe it can be assumed that if a milk plant is close enough to an atomic blast to be seriously contaminated with radioactive materials, it will have been destroyed or severely damaged by the blast or thermal radiation effect. Undestroyed milk and milk products in the central area of the explosion which have been exposed to heavy neutron-induced contamination should be disposed of. Milk products in undisturbed sealed containers which were exposed only to "fall-out" or "surge mists" will probably be safe for consumption; however, the outside surfaces of the containers must be washed to remove adhering contamination (4).

According to currently accepted principles, milk plants and their equipment exposed to "fall-out" or radioactive mists can be decontaminated by washing and scrubbing down exposed surfaces followed, if required, by the use of citric or muriatic acid. Since radioactive decay is entirely unaffected by chemical reactions the removal of induced radioisotopes, fission products, and unfissioned particles is necessary (4).

Milk and milk products directly exposed to chemical warfare agents must be destroyed. After an attack, facilities and products in sealed containers must be decontaminated before use in accordance with the instructions applicable to the agent or agents used.

The use of various biological agents by the enemy presents special problems which are now being studied by our military establishment and others. Procedures for rapid detection of the use of such agents have been initiated in the United States based on an epidemiological intelligence system for prompt reporting and study of disease outbreaks. Milk and milk products provide an excellent medium for the conveyance of some of the possible biological warfare agents that might be used; however, the processing of milk at high temperatures does provide a high degree of protection against

some of these organisms. It can be anticipated that the enemy will develop heat-resistant strains of pathogens and will also use toxins. Therefore, plans must be developed for the protection of milk plant operations against the possible introduction of biological agents through sabotage activity of enemy agents.

Research and Development Needs

Some of the problems related to milk supply in times of civil disaster, on which we believe further research to be required, are:

1. The use of chemical preservatives and sterilizing agents as a substitute for the heat treatment of milk.

2. Field screening tests for the rapid detection of radioactive and chemical contamination of milk, as well as improved laboratory procedures for the rapid detection of various biological agents and toxins that might be added to milk.

Coordination of Plans and Organization

Plans for milk control services in civil defense must be worked out in detail to fit the specific problems and probable disaster conditions for each likely target area, and must be integrated with the plans of communities designated to provide assistance and support in case of wartime civil disaster. They should then be carefully integrated into, and coordinated with, other civil defense plans at local, State, regional, and Federal levels. It is, of course, of paramount importance that the milk industry and its organizations participate in the development of all plans.

Food Sanitation Problems In Emergency Feeding

By GORDON E. McCALLUM, B.S.
JOHN D. FAULKNER, M.S.
STEPHEN E. KOELZ, M.P.H.

Emergency food sanitation problems are extremely complex. In solving these problems many of the specific procedures and techniques generally considered to be fundamental in food sanitation will have to be altered.

Factors which normally take precedence in the development of plans concerning administrative and scientific problems related to food supply and emergency feeding in civil defense operations include: (a) adequacy of sufficient amounts of principal food items required for the feeding of casualties, refugees, evacuees, and other homeless persons; (b) a consideration of the need for possible rationing and distribution of food and supplies; (c) the availability of emergency facilities and equipment for adequate storage, preparation, and service of food; and (d) food sanitation. We will deal only with food sanitation problems as they affect the operation and administration of emergency feeding programs.

The possibilities of disease dissemination will be greatly increased at times of emergency mass feeding so that adequate control measures will be essential. Therefore, the specific measures directed toward the protection of food assume added significance over those normally practiced.

The principal problems in the establishment of safe food service under emergency conditions relate to: (a) the use of equipment and the selection of foods in menu planning for varying degrees of emergency conditions; (b) the train-

Mr. McCallum is chief of health emergency planning of the Office of the Surgeon General, Public Health Service. Mr. Faulkner is chief and Mr. Koelz is food sanitation consultant of the milk and food branch, Division of Sanitation, Public Health Service.

ing and mental attitude of all personnel responsible for handling of food, and (c) the development of emergency sanitation standards for controlling food-borne disease hazards which are likely to occur during a wartime civil disaster.

Sanitation Programs and Control Procedures

The application of known techniques to food sanitation problems will be complicated by the magnitude of the disaster. It would, of course, be desirable to maintain existing food sanitation and to intensify control procedures. Although this will not be possible, the basic and well-established sanitation principles discussed below will be applicable.

Storage Problems

One of the basic needs in the efficient operation of food service facilities is the adequate storage of food materials, including water, milk, and other food supplies. The storage problem is significant principally because emergency food service usually requires quantity feeding. Storage facilities, therefore, will need to be considered with respect to the construction and design of large storage utensils, refrigeration equipment, and the type of raw food materials to be used in the preparation of the finished food product. The use of packaged and bulk foods requiring little preparation and a minimum or no refrigeration appear to be indicated for use in emergency feeding operations, especially in the immediate postdisaster period.

Wholesomeness of Food and Drink

The wholesomeness of the food is directly related to the storage facilities of emergency feeding operations. This is particularly true when food supply plans provide for the distribution of perishable foods directly to mass feeding centers and other food service establishments. Refrigeration is required for such foods, whether they are distributed in small amounts, in packaged form, or in bulk. Unless adequate equipment and utensils are provided, the use of readily perishable foods should be limited to the amounts to be served at one feeding. In many instances the mere substitution of food

and drink which do not require temperature control measures is advisable.

Cleaning and Bactericidal Treatment

The importance of adequate cleaning and proper bactericidal treatment of equipment and utensils cannot be overemphasized. Even under normal conditions, we encounter difficulties in obtaining compliance with this important item of food sanitation. Under emergency feeding conditions the problem will be extremely complex, since special adaptation of established techniques and procedures to varying types of emergency feeding centers will be required.

The public health significance of maintaining thoroughly clean multi-use eating and drinking utensils and equipment is well known. Not so well known, however, is the fact that some methods of bactericidal treatment are not effective unless all soil has been removed from the surfaces to be treated. This is particularly true when chemical germicides such as hypochlorites are used. Therefore, only after thorough cleaning of such utensils should one or both of the following bactericidal processes, or equivalent processes which appear suitable for emergency feeding operations, be applied.

1. Complete immersion in hot water at a temperature of 170° F. or above. The immersion time will vary from 2 minutes' exposure in water at 170° F. to approximately 30 seconds' exposure at boiling temperatures (1). This method we believe to be the preferred procedure for emergency feeding operations.

2. Immersion in a chlorine or other chemical germicidal solution. Strengths of solution and exposure times will, of course, vary with the agent used and its concentration (1).

To reduce both hazardous conditions and workload at emergency feeding centers, it appears advisable to utilize single-service containers and eating utensils, whenever practicable, as substitutes for multiservice plates, cups and glasses, and knives, forks, and spoons. The use of such single-service containers may also be required due to shortages of water for cleaning.

Other Sanitation Problems

To reduce both hazardous conditions and workload at emergency feeding centers, it appears advisable to utilize single-service containers and eating utensils, whenever practicable, as substitutes for multiservice plates, cups and glasses, and knives, forks, and spoons. The use of such single-service containers may also be required due to shortages of water for cleaning.

Other Sanitation Problems

Other matters of sanitary significance which have a direct bearing on safe food service at

with abundant light, good ventilation, potable water, and an adequate supply of hot water and steam. Meat inspectors are present whenever the plants are operating. The Meat Inspection Service of the Federal Government has served as a model for inspection systems set up in the various States and municipalities.

Since meat is a highly perishable food and for the most part is utilized in the fresh state, rather elaborate systems of refrigeration have been provided. All meat packing plants make a practice of getting the meat into refrigerated rooms as soon as possible. Sometimes, the product goes almost immediately into a low-temperature freezer.

Disaster Effects on Meat Production

Any interference with the normal flow of livestock from the farm to the market and through the meat packing plants may result in serious losses. Problems which result from floods, fires, windstorms, and the like, may be greatly magnified in time of a national emergency. Many of our meat packing establishments are located in large cities which might be regarded as target areas. An attack by bombing or shelling could seriously interfere with the normal supply of such services as heat, light, water, refrigeration, and waste disposal.

An attack with atomic bombs could have vastly greater devastating effects because of their tremendous blast and fire power, and disruption of meat production resulting from such blast and fire is our principal concern.

In addition, there is the problem of radioactivity. Since it is unlikely that there would be large concentrations of livestock in an area where an atomic bomb is exploded, the number

of animals exposed to the rays given off at the time of the explosion would likely be rather small. Such animals could be slaughtered and used for food if this is done before any symptoms of radiation sickness develop.

While the possibility of dangerous contamination from residual radiation is rather remote, this possibility should not be overlooked. Animals exposed to radioactive material such as the "fall-out" from an atomic bomb or from material in which radioactivity has been induced should be handled with caution. Persons handling such animals, whether farmers, packing plant employees, or inspectors, should be assured by monitors of the safety of approaching the animals before proceeding with slaughter. Such monitoring service would also assist the veterinarian in determining whether or not it would be safe to allow the meat from such an animal to be used for food. The monitor should also be available to advise the inspector concerning the location and nature of any radioactive material which might have been taken into the body of the animal. The kind of such radioactive material and its location would determine the disposition of the meat.

In making plans to safeguard our meat supply in the event of a local disaster, every attention has been given to making certain that the public hysteria will not be heightened by concern with the wholesomeness of the food supply. As a result, no consideration has been given to lowering accepted meat hygiene standards. Rather than thinking of lowering standards, it is our present belief that the public in time of stress is entitled to the type of planning that will give proper safeguards to its food and assure an adequate supply.

Handling of Meat In an Emergency

By CLARENCE H. PALS, D.V.M.

In the United States our per capita consumption of meat is about 145 pounds per person annually. This is divided approximately as follows: beef, 63 pounds; veal, 9 pounds; lamb and mutton, 5 pounds; pork, 68 pounds. We also consume large quantities of poultry. This amounts to about 25 pounds of chickens, about 4 pounds of turkeys, and smaller amounts of ducks and geese per person annually.

Since meat is a highly perishable food, its preparation and handling must be surrounded by safeguards. The consumer of meat has a right to know that the meat he eats has been derived from healthy animals and has been handled in a manner to assure him that it is clean, sound, wholesome, and free from adulteration.

Meat Inspection Service

The animals we use for food, mainly cattle, sheep, goats, and swine are subject to a wide variety of diseases and conditions which might make their meat unsuitable for human food. Some of the diseases are transmissible to humans. One of the principal functions of any meat inspection service is to remove from food channels any meat which is not suitable for human consumption. This can only be accomplished by trained inspectors making careful inspections at all stages of the preparation of meat from the live animal until it is processed and delivered to the consumer. The live animals should be carefully examined on the day of slaughter by competent inspectors in order to assure the removal of those animals which are unsuitable for meat production. It is essential that competent veterinary inspection be provided so that an autopsy may be performed on every animal at the time of slaughter to as-

sure the removal of those carcasses or parts of carcasses which are unsuitable for human food.

In the United States the Federal Meat Inspection Service is charged with the responsibility for inspecting all meat and meat-food products prepared in plants whose products move in interstate or foreign commerce. Meat and meat-food products prepared in plants that sell their product entirely within the State where produced are subject to any inspectional requirements of the city, county, or State in which they are located.

During the past year, our Federal Meat Inspection Service inspected nearly 90 million animals at the time of slaughter. This is more than 80 percent of the animals slaughtered commercially in the United States. About 300 thousand carcasses were condemned in their entirety and nearly 2 million parts of carcasses, principally heads, were condemned for human food and destroyed. Because they were found to be unsuitable for human food, nearly 1.75 million beef and calf livers were condemned for edible purposes and destroyed.

Another important function of the Meat Inspection Service is to inspect the preparation of meat food products, such as hams, bacon, sausage, loaves, canned meats, lard, and shortening, to assure that such products are clean, sound, wholesome, free from adulteration, and informatively, but not deceptively, labeled. Nearly 16 billion pounds of such products were prepared under the supervision of Federal meat inspectors during the past year.

Plant Supervision

The supervision of slaughtering and processing operations in about a thousand plants operating in all parts of the United States requires a well-organized group of veterinarians and meat inspectors working together. Antemortem and postmortem inspection is conducted by veterinarians along with well-trained lay assistants. The inspection of meat and meat food products after slaughter is performed primarily by trained meat inspectors working under the supervision of the veterinarians who have the over-all inspectional responsibility. Federally inspected establishments are required to be in well-constructed buildings supplied

conditions, the use of safety devices, and the application and adequacy of accidental and occupational disease legislation in relation to cancer.

From the relatively specific character of the known and suspected occupational carcinogens, it follows that one must expect an uneven distribution of occupational cancer hazards among the various States, depending on the kind of natural resources present and the specific occupational activities and industrial operations carried on in the States. Each State, therefore, is likely to present an occupational cancer pattern of its own, and would do well to develop a study and control program adapted to its special needs and best suited for preventing, containing, counteracting, or eliminating its particular occupational cancer hazards.

State-Wide Control

The primary objectives of occupational cancer surveys are the collection of reliable data on the incidence rates, site, sex, race, age distribution, and nature and types of exposure to exogenous causal factors of cancers occurring among various occupational groups. Only when sufficient basic information on these aspects of occupation cancers and cancer hazards is available, is it feasible to develop and institute rational and effective control measures. Such studies may employ morbidity data, mortality data, or a combination of both, depending upon the type of investigation most suitable for the industrial conditions in a particular State and for the kind of tumors and population groups to be analyzed for the presence of occupational cancers.

These investigations on cancer morbidity and mortality are aimed at ascertaining whether cancers of certain sites tend to occur with unusual frequency in specific geographic areas or among selected industrial groups. To determine the number and to identify the types of exposed employees, as well as the types and intensities of exposures sustained, it is advisable to conduct surveys of industrial establishments and workshops which, according to information available in the State division of industrial hygiene, produce, use, or handle known or suspected occupational carcinogenic

agents or devices. These surveys should be made either before beginning the investigations or supplementary to them.

Morbidity Studies

The use of morbidity data has a fundamental advantage over use of mortality data. In using morbidity data an attempt is made to determine all cases of cancer in the population surveyed regardless of whether the individuals are employed in a specified industry, are retired, living, or dead, or are engaged in other types of work subsequent to employment in a hazardous operation; whether the cancerous disease is present or symptomatically arrested; whether it was the cause of death, disability and retirement, or a passing event unrelated to the state of health at the time of the survey or to the cause of death, if death has occurred.

This method makes it possible to obtain information by which the total actual and organ specific cancer incidence among the total number of effectively exposed individuals can be approximated. By interrogation of living cancer patients, direct or indirect information on the employment history, specific exposures sustained, diseases preceding or accompanying the development of cancers and possibly related to their etiology may be obtained. The morbidity approach is the most suitable one, if occupational cancers with a high rate of cure, such as skin cancers, are to be studied. Since occupational cancers as a rule do not manifest themselves in an acute, epidemic-like fashion, to obtain valid results, it is necessary to analyze cancer incidence figures for a period of not less than 5 years, unless large population groups are surveyed or there is an unusually high frequency of cancers present in a restricted group studied.

Mortality Studies

Health Jurisdiction Records

Death certificates in the United States have been uniform since 1940, with revisions every 10 years, in accordance with the changes of the Manual of the International Statistical Classification of Diseases, Injuries, and Causes of Death. Although the data recorded on these

Studies of Occupational Cancer

By W. C. HUEPER, M.D., and THOMAS F. MANCUSO, M.D.

State health departments are in an especially favorable position to pursue occupational cancer studies, because of their organization and the authority vested in them by law. With few exceptions, State health departments have in their organizations the personnel and facilities essential for such investigations, including the three basic divisions—cancer control, biostatistics, and industrial hygiene—each of which has a special and separate interest in the problem of occupational cancer. The extensive practical experience available from communicable disease studies conducted in the past is an additional advantage to State health departments in the development of effective occupational cancer control programs, since the methodological approaches employed in epidemiological studies of occupational cancers are similar to those used for many years in the study of epidemiology and control of communicable disease.

The official status of State health departments provides them with opportunity to obtain access to, and collect a large variety of, pertinent records on cancer patients. Apart from information on death certificates, records of workmen's compensation boards, and histories of cancer patients kept by physicians, hospitals, cancer registries, industrial medical and employment departments, labor unions, and insurance companies, State health depart-

ments can draw on the facilities of the Federal Bureau of Old-Age and Survivors Insurance. In addition to data on the employment history of all insured individuals and on employers and industries, this bureau has the names and last addresses of all workers employed since 1937 in each State and in all industrial establishments in the United States. In States in which State disability insurance agencies exist, the State health department has an opportunity to obtain occupational data from living cancer patients.

Cancer control funds provided by the National Cancer Institute to the individual States enable State health departments to implement occupational cancer control programs. In addition, important exploratory investigations on occupational cancer may be supported by special cancer control grants.

Industrial Exposures

State health departments possess information, usually collected by the division of industrial hygiene, on agents handled, products made, and processes used in individual plants. Supplementary data on special aspects of occupational exposures can be obtained when needed because State laws usually authorize representatives of State health departments to enter industrial establishments to study occupational health hazards to the workers employed and environmental industrial health hazards to the population living or working within their waste disposal zone. The study of occupational cancers can be extended through the cooperation of State labor departments to observation of the laws governing working

Dr. Hueper is chief of the carcinogenic studies section, cancer control branch, National Cancer Institute, National Institutes of Health, Public Health Service; Dr. Mancuso is chief of the division of industrial hygiene, Ohio State Department of Health.

conditions, the use of safety devices, and the application and adequacy of accidental and occupational disease legislation in relation to cancer.

From the relatively specific character of the known and suspected occupational carcinogens, it follows that one must expect an uneven distribution of occupational cancer hazards among the various States, depending on the kind of natural resources present and the specific occupational activities and industrial operations carried on in the States. Each State, therefore, is likely to present an occupational cancer pattern of its own, and would do well to develop a study and control program adapted to its special needs and best suited for preventing, containing, counteracting, or eliminating its particular occupational cancer hazards.

State-Wide Control

The primary objectives of occupational cancer surveys are the collection of reliable data on the incidence rates, site, sex, race, age distribution, and nature and types of exposure to exogenous causal factors of cancers occurring among various occupational groups. Only when sufficient basic information on these aspects of occupation cancers and cancer hazards is available, is it feasible to develop and institute rational and effective control measures. Such studies may employ morbidity data, mortality data, or a combination of both, depending upon the type of investigation most suitable for the industrial conditions in a particular State and for the kind of tumors and population groups to be analyzed for the presence of occupational cancers.

These investigations on cancer morbidity and mortality are aimed at ascertaining whether cancers of certain sites tend to occur with unusual frequency in specific geographic areas or among selected industrial groups. To determine the number and to identify the types of exposed employees, as well as the types and intensities of exposures sustained, it is advisable to conduct surveys of industrial establishments and workshops which, according to information available in the State division of industrial hygiene, produce, use, or handle known or suspected occupational carcinogenic

agents or devices. These surveys should be made either before beginning the investigations or supplementary to them.

Morbidity Studies

The use of morbidity data has a fundamental advantage over use of mortality data. In using morbidity data an attempt is made to determine all cases of cancer in the population surveyed regardless of whether the individuals are employed in a specified industry, are retired, living, or dead, or are engaged in other types of work subsequent to employment in a hazardous operation; whether the cancerous disease is present or symptomatically arrested; whether it was the cause of death, disability and retirement, or a passing event unrelated to the state of health at the time of the survey or to the cause of death, if death has occurred.

This method makes it possible to obtain information by which the total actual and organ specific cancer incidence among the total number of effectively exposed individuals can be approximated. By interrogation of living cancer patients, direct or indirect information on the employment history, specific exposures sustained, diseases preceding or accompanying the development of cancers and possibly related to their etiology may be obtained. Mortality Studies

Health Jurisdiction Records

Death certificates in the United States have been uniform since 1940, with revisions every 10 years, in accordance with the changes of the Manual of the International Statistical Classification of Diseases, Injuries, and Causes of Death. Although the data recorded on these

documents are not always reliable and sometimes are incomplete, death certificates provide one source of information on which studies of the incidence and the epidemiological patterns of cancer as related to industrial employment and occupation may be based. Death certificates are available on a state-wide basis from the division of vital statistics of the State health departments and on a regional basis at the local county and city health organizations. The data are recorded in "death volumes" in accordance with health jurisdiction—name of deceased, place of death, and date of death—and include information on age, sex, race, occupation, and social security number, in addition to the primary and secondary causes of death. In the production of the annual report of the State health department, the "State sheets" are prepared from information on mechanical punch cards on which essentially all the data on the death certificates are transcribed in coded form. For the coding of occupational and industrial employment data, the classifications of the Bureau of Employment Security, Social Security Administration, published in 1949 as "Dictionary of Occupational Titles," may be used.

Whenever such punch cards are available for an adequate number of years or can be prepared from the death volumes, a rough statistical analysis can readily be made to determine the total number of cancer deaths, the cancer deaths by organs, and their distribution among various geographic regions, occupations, industries, sexes, age groups, and races. Experience has shown that this particular methodological approach, when made on a State-wide basis, is not especially informative if industries are diversified and well distributed throughout the State. On the other hand, promising leads can be obtained by this technique, if the State has relatively well-defined industrial, urban, and rural areas and industries of certain types predominate in some areas but not in others, that is, if there are regions with differing industrial patterns and thus of different potential cancerigenic hazards. Such conditions may be reflected in regional differences in the total number of deaths from, and in the distribution of, cancers among different organs, sexes, ages, races, and occupations.

This methodological approach appears to

have definite limitations when applied on a state-wide basis. The procedure, on the other hand, has been found more practicable for obtaining important leads on occupational cancer hazards when applied to specially selected regions, counties, or cities having either unusual types of industries or one predominating type of industry. Under such conditions it is possible to ascertain whether relatively definite evidence exists suggesting an occupational or environmental cancer hazard related to the activities of the particular industries present.

Whenever statistical analysis of the data on such a regionally restricted survey of cancer incidence based on death certificates demonstrates an excessive frequency of one or several types of cancers among the population group studied, a serious effort should be made to determine the reliability of the data used, that is, a check of the cancer diagnoses and personal medical and occupational histories should be made. Steps might then be taken to establish the validity of the evidence by broadening the study and elaborating upon the observations. The medical, employment, and insurance records of the industries located in the survey area might be investigated for additional information on the incidence of cancers among workers formerly or presently employed in the various operations, to pinpoint the potential carcinogenic operation or operations and to obtain a lead as to the nature of the carcinogenic agent or procedure involved.

Once this goal has been reached for a circumscribed population group or industry, it is rather simple to extend the procedure to other population groups and industries within the State where similar exposures might prevail. A master list of the names, birth dates, and addresses of persons who over a period of years died of cancers involving organs under study is prepared from the death volume. It is submitted to the industrial concerns of the area to be surveyed, with a request to indicate those individuals they had employed, the departments in which—and jobs at which—they worked and the dates of employment in each of these departments. In this manner pertinent information becomes available on exposures formerly sustained by deceased cancer patients while working for different employers. This

evidence then has to be analyzed and weighed for its significance in regard to the type and site of cancer studied.

If the results of such studies in occupational cancer epidemiology and etiology should prove their usefulness to a State health department, the above-described plan may be incorporated among the routine procedures of disease control. Under such a scheme the industrial concerns of the State are circularized at the end of each year with a list containing the names of cancer patients who died during this particular year. The industries are requested to check the names given against their personnel records and to note previous employment with the company and the years and types of employment. In States with cancer registries, this scheme can be applied also on a cancer morbidity basis.

Information of this type collected over several years and analyzed at regular intervals should prove of great value in discovering carcinogenic operations and occupations within the industries of a State or region.

Industrial and Occupational Group Data

The second survey method for the determination of occupational cancer hazards and cancer deaths utilizes the information on death causes by organizational groups of industrial workers either employed in the same type of industry, or following the same trade, or exposed to the same known or suspected occupational carcinogenic agent or agents. With this approach, it is possible to determine the relative incidence of death from cancers of various sites occurring among members of different labor unions or professional organizations, such as operating and nonoperating railroad employees, photo-engravers, steelworkers, automobile workers, rubber workers, firemen and oilers, electrical workers, hod carriers, chemical workers, machinists, asbestos workers, boilermakers, teamsters, bookbinders, and technical engineers.

The records of some labor organizations contain data on the various employments and different types of work followed by their members. Types and durations of exposure to occupational carcinogenic agents which the individual members may have sustained during their lifetime can be deduced from this information. Whenever such detailed information

on the occupational histories of union members is available, the degree of dilution of any evidence suggesting the existence of an occupational cancer hazard for the members of the organization studied is considerably reduced, and the significance of the observations made is thereby increased.

Information obtainable from death certificates from labor unions, and from records from disability insurance agencies and cancer registries also offers an opportunity to approach the epidemiology and etiology of occupational cancer from the viewpoint of exposure to the same occupational agent found in different trades and industrial organizations. Such studies are advantageous in that observations made among the members of one occupational group, if valid, should to some extent apply to other occupational groups having an identical exposure.

In this country, the Bureau of Old-Age and Survivors Insurance can provide the names and addresses of companies which manufacture or use similar products or operations in any particular State. The names and total employment histories of former employees of such companies, against whose accounts death claims have been made, can be obtained from the same source. Whenever the social security number has not been listed on the death certificate, an attempt may be made to obtain it from the informant. To verify the data furnished by the Bureau of Old-Age and Survivors Insurance and to extend them into the field of specific information as to the job or jobs held, a query should be addressed to the former employer. The cause of death can be ascertained from the death certificate. With such basic data on hand, a statistical analysis can be made to determine the incidence rate and types of cancers among members of different occupational groups having contact with the same known or suspected occupational cancerigenic agent.

Previous Employment Records

In the third method of studying occupational cancer, verified data obtained from death certificates are related to information on previous employments supplied from the records of the Bureau of Old-Age and Survivors Insurance (BOASI), Social Security Administration,

Baltimore, Md. This bureau has in its files a record of all places of employment of individuals who are covered under the Social Security Act. Since the information on employment available at this bureau includes all States in which an individual may have been employed for some time, it alleviates to a large extent the difficulty of assessing the role of all occupational factors resulting from the frequent migration of industrial labor from one State to another.

At present, the main limitation of this approach is that in many instances, especially in older workers, employment records of the insured group do not include the entire employed period of life, as the records were started only some 14 years ago (1937), and thus may not always be adequate for covering the entire known and long latent periods of occupational cancers.

The second deficiency of the employment information kept by BOASI is related to the fact that such data are recorded only for persons who are insured. They, therefore, do not apply to that part of the working population which does not fall within the Social Security Act in its original or recently amended form. However, with succeeding years, this source of information is certain to become increasingly valuable for the discovery of occupational cancer hazards, especially as the records of BOASI offer an opportunity to determine the cause of death of all deceased workers once employed in any plant or industry. Thus, attack rates of cancers with a predominantly fatal outcome can be computed from this material for the total effectively exposed worker population of an individual industrial establishment as well as of an entire industry.

Moreover, this methodological approach can be used on surveys of limited scope, such as the determination of the occupational background of cancers of specific organs. An adequate number of cases, however, must be used in such a study, and proper cognizance must be taken of the long latent periods of occupational cancers. Such investigations, undertaken on a state-wide or, perhaps even better, on a nation-wide basis in order to include any possible regional differences in the occupational or environmental cancerigenic spectrum, might yield within a relatively short time and with comparatively

moderate efforts, valuable information on the epidemiology and etiology of human cancer.

Comments

From the foregoing discussion on the role of the State health department in the control of occupational cancer, it should have become evident that State health departments not only have an important stake in this problem but are in an especially favorable position of assessing its scope as to etiology, epidemiology, and control.

The active participation of State health departments in occupational cancer studies is most desirable since experiments in exogenous carcinogenesis, while providing valuable information, do not give results directly and unequivocally applicable to man. Observations in human carcinogenesis, therefore, are essential for definitely ascertaining the various physical, chemical, and parasitic factors in the human environment which may cause cancer in man.

In several industrialized European countries, especially England, official agencies in existence for several decades are charged with the routine study of industrial cancers. From these countries, extensive statistical data are available on the incidence, epidemiology, and etiology of occupational cancers. In contrast, there is an utter lack of similar information in the United States although our country possesses by far the largest industrial establishments. The time has come when this gap in sound public health practice should be closed, and obvious cancer hazards which affect not only certain occupational population groups but also, in part, the population in general, can be properly assessed and brought under effective control.

The various methods proposed, most of which have proved their practicability in field studies, provide State health departments with ready-made approaches to such investigations. Depending upon the organizational machinery in a particular State, and on the special occupational cancer hazards present, one or several of these methods may be found most suitable for the development of a program of occupational cancer control.

While it is possible, with the methods de-

scribed, to engage in the study of certain phases of the occupational cancer problem on a nationwide basis (determination of occupational background for specific organ cancers; prevalence of specific cancers among workers of specific industries; occurrence of cancers among different types of industrial workers and industries producing, using, or handling known or suspected carcinogenic agents), State health departments can make similar investigations more effectively

and reliably if they create adequate facilities for such work.

The rapidly increasing importance of chronic disabling diseases in public health practice applies also to cancer. Doubtlessly, the most promising approach to attain a reasonable control of this disease is through an attack on those types of cancers, the occupational cancers, of which the etiology is known or can be ascertained with available methods.

Field Test Study of the Membrane Filter

Under the auspices of the Standard Methods Committee for the Examination of Water and Sewage of the American Public Health Association, a field test study of the membrane filter was begun July 1, 1952. The study is co-sponsored by the American Water Works Association and the Public Health Service. It will be continued for 52 weeks.

Twelve official laboratories accepted invitations to participate in the study: department of health sanitation laboratories of California, Georgia, Indiana, Kansas, Massachusetts, New York, Texas, and West Virginia; and water works laboratories serving Detroit, Indianapolis, New York City, and St. Louis. The study is being coordinated by the Environmental Health Center, Public Health Service, Cincinnati, Ohio.

The membrane filter technique for the determination of coliform organisms and the standard five-tube, three-dilution, most-probable-number procedure will be carried out simultaneously on all water samples. As many different surface and ground water sources as possible will be examined by each laboratory. In addition to the bacteriological procedures, the following physical and chemical tests will be made: pH, alkalinity, turbidity, color, hardness, and oxygen consumed.

It is expected that information from this study will enable the Standard Methods Committee to make recommendations relative to the applicability of the membrane filter technique to the examination of water.

A previous study of the membrane filter technique was reported by Harold F. Clark et al., of the Environmental Health Center, in *Public Health Reports*, July 27, 1951.

Representatives of each of the 12 laboratories participating in the present study attended a course given April 22-25, 1952, on membrane filter procedures at the Environmental Health Center.

Use of Field Tests in Evaluating Detergents

By J. L. MINKIN, M.S.

Can the evaluation tests for dishwashing detergents be used under practical field conditions?

What equipment and how much chemical knowledge is needed?

Can the tests be easily demonstrated to the restaurant operator?

Will the results be of practical value?

Sanitarians attending the New York State Public Health Environmental Sanitation Field Training Center at Buffalo, N. Y., are getting the answers to these and other questions concerning tests for dishwashing detergents. In the food and restaurant portion of the 12-week field training course, they are obtaining practical experience in evaluating detergents, experience which will aid them in making their routine inspections of restaurants and in helping the restaurant operator select a detergent for his particular needs.

Laboratory Evaluation Studies

Much work has been done on the laboratory level to evaluate detergents and to test their performance in dishwashing machines. Such recognized authorities as the National Sanitation Foundation at Ann Arbor, Mich., and the Environmental Health Center, Public Health Service, Cincinnati, Ohio, have made some excellent studies of these problems. Their tests, however, have been made with the use of rather elaborate testing and control equipment—photometers, analytical balances, experi-

mental dishwashing machines, and other complicated laboratory equipment—and therefore cannot be carried out by the sanitarian in his routine inspection or by the restaurant operator.

A detergent that has been determined to be satisfactory under laboratory conditions in all probability will be satisfactory under field conditions if such factors as mechanical condition of the dishwashing machine, length of washing time, temperature of the water, and concentration of the detergent are at the recommended level. In addition, the actual use-value of the detergent will depend upon the efficiency of the operator and how much "elbow grease" and effort has been put into scraping and prerinsing the dishes. Since the laboratory test cannot control all of these variable factors, there is a need for a simple field performance-use test.

In our field training course we have developed a series of simple demonstrations to evaluate detergent properties, and a dish-soiling mixture for test-plate demonstration use in the single-tank dishwashing machine, the type most commonly used in restaurants that have mechanical dishwashers.

Detergent Properties

Sodium carbonate, a host of alkali cleaners, water softeners, balanced detergents, wetting agents, and synthetic cleaners are among the almost unlimited number of substances that are detergents. In our field demonstrations, the detergents are evaluated on the basis of tests for the following properties:

1. Ease with which the detergent dissolves in the water used.
2. Control of water hardness and film deposit.
3. Foaming ability.
4. Wetting ability.
5. Emulsification ability.
6. Ability to dissolve and deflocculate proteins.

Demonstration of Detergent Properties

The demonstration of detergent properties, using the basic chemicals usually found in a balanced detergent, illustrates dramatically that no single chemical has a high degree of all the desired properties. A good general purpose detergent must be a mixed and properly balanced product.

Mr. Minkin is assigned to the New York State Public Health Environmental Sanitation Field Training Center at Buffalo, N. Y. This center is sponsored jointly by the New York State Department of Health and the Public Health Service Communicable Disease Center at Atlanta, Ga.

The usual recommended detergent concentration ranges from 0.25 to 0.5 percent. For these simple tests, this is about one-half teaspoon of detergent powder in one-half pint of water. This measure is only approximate, but if all measurements are similar and the detergents have nearly the same specific gravity, the results will be comparable.

If detergents being tested vary from heavy granular materials to light fluffy particles, such differences should be taken into consideration in comparing the results of the tests. Measure by weight is, of course, more accurate than measure by volume.

Warm water should be used for these tests, to approximate actual operating conditions. The detergent solution may be mixed in a half-pint milk bottle, a glass, or any clear container.

The demonstration of detergent properties should proceed as follows:

1. *Ease with which it dissolves in the water.* Add one-half teaspoon of a basic chemical or a detergent to one-half pint of warm water and stir 25 times. A good detergent will be completely soluble and will yield a clear solution.

2. *Control of water hardness and film deposit.* Examine the solution carefully for cloudiness and sediment. Such deposits may be from the detergent itself, or they may be precipitated water hardness or insoluble soaps. These deposits can form films on dishes, making rinsing difficult. A well-balanced detergent will control water hardness by sequestering the hardness and keeping it in suspension or solution.

3. *Foaming ability.* After the detergent solution has been mixed and stirred, examine it for foam. Foaming ability is desired in detergents for washing by hand but must be limited for machine washing, since a high-foaming detergent will be quickly pumped out of a machine and spilled onto the floor.

4. *Wetting ability.* This property is desired in detergents to help separate soil from the dish. It can be demonstrated by putting a drop of the detergent solution on waxed paper. Water, with high surface tension and low wetting ability, will stand up in a spherical droplet. A detergent high in wetting ability will have a drop that flattens out over the waxed paper. Again, the difference may be demonstrated by

allowing the drops to roll off the paper and examining the tracks. Water alone will not wet the waxed paper and will not leave a track. A good wetter will leave a wet track film. Plastic dishes may be used instead of waxed paper.

5. *Emulsification of fats.* Emulsifying ability may be shown by adding one-half teaspoon of vegetable salad oil to the detergent solution and stirring 25 times. A count in seconds of the time required for the oil to separate out at the surface will measure this property of the detergent.

6. *Ability to dissolve and deflocculate proteins.* Although the above solution may be used for this test, a better test can be made with a fresh solution. Again add one-half teaspoon of detergent to one-half pint of warm water. To this add a few grains of dry cottage cheese. Then stir the mixture until it shows complete deflocculation and/or dissolving of the cheese. The number of times the solution is stirred is the measure of the ability of the detergent to dissolve and deflocculate proteins.

As each detergent is given each of the six tests, the results are recorded. After all the detergents under consideration have been tested, classification and selection is made by examining the scores of the products. Although small differences between detergents cannot be distinguished, the products can be classified as poor, fair, good, or excellent. The product scoring high in the greatest number of properties is the best of the group. In our classes, the trainees selected detergents from a group of over 25 commercial products for use in a single-tank dishwashing machine after seeing the demonstrations with the basic detergent chemicals.

The sanitarian and the restaurant operator are interested in selecting a suitable detergent for the available water supply. The chemical and physical characteristics of water, of course, vary in different parts of the country and at different times of the year. Even in a community in which the water supply is under competent water-plant-treatment control, the characteristics of the water may change during the year.

In addition to the basic water problem, the type of restaurant will influence the selection

of a detergent. The full-course-dinner restaurant will have use for several types of detergents, while a short-order bar may need only a single detergent.

The final selection of a detergent for use in a particular restaurant is not a simple problem. In addition to the above factors, availability and ease of handling must be considered.

Test-Plate Demonstration

It is generally agreed that the best test of a detergent is a use-performance test under normal operating conditions. This test can be made by using separate soils and a series of tests as given above, or by using a standard test soil applied to a plate. The latter method is the accepted practice. It has been used in laboratory and field appraisal of mechanical dishwashing installations. This method, however, presents two problems: (1) What should be the composition of a standard soil? (2) How should the soil be applied to the test plate? Breakfast, lunch, and dinner dishes all differ in the number of dishes per meal, the types of dishes, and the soil residue to be removed.

There is a difference of opinion as to whether dishes are soiled by separate food soils or by mixtures of food soils. From our experience here we have concluded that the soil on dishes is usually a mixture; it may be a mixture of fats, proteins, and carbohydrates, or of only two of these food substances. For our use-performance test, we made a simple standard test soil of these three food substances. The mixture is composed of easily obtainable materials, which can be mixed by simply stirring and shaking. Although the materials may separate after long standing, they may be easily remixed by simply shaking the mixture a few times. If a preservative such as sodium benzoate is used, the mixture has good keeping qualities.

The standard soil was made by mixing—

- 1 medium-sized whole egg
- 50 ml. evaporated milk
- 50 gm. white flour
- 100 ml. vegetable salad oil
- 100 ml. distilled water
- 5 gm. activated carbon
- 5 gm. sodium benzoate (as preservative)

The performance test is made by putting 1 ml. or 1 dropperful of the soil onto a plate,

spreading it evenly over the central area, and drying by hot air, or the mixture may be placed on a hot plate. The test plate is then put into a tray of scraped and prerinsed dishes for the machine dishwashing. After the washing process, the test plate is examined for soil removal.

A properly operating dishwashing machine using the proper detergent and the recommended water temperature will completely clean the plate in the recommended washing time. In our single-tank dishwashing machine, the test-soiled plate was completely cleaned by washing at 140° F. for 30 to 45 seconds.

This test is a severe test of both detergent and machine. If the plate is not completely cleaned, one or more of the variable factors should be investigated. Failure may be due to the type of detergent, concentration of detergent, temperature, length of washing time, or mechanical condition of the machine.

Summary

Practical evaluation of detergents can be made by simple tests for each of six detergent properties. The six properties are: (1) ease of solution, (2) foaming ability, (3) control of water hardness and film deposit, (4) wetting ability, (5) emulsification of fats, and (6) dissolving and deflocculation of proteins. These tests can be made with very elementary measuring tools—a teaspoon, a half-pint milk bottle, and visual observation of results. A knowledge of sanitary chemistry is not needed for the tests to be demonstrated by a sanitary inspector or to be understood by the restaurant operator.

Although fine differences in detergents cannot be detected by these simple tests, the detergents can be classified broadly as poor, fair, good, or excellent.

After a detergent has been selected for use in a machine dishwasher, its performance can be tested by a test-plate demonstration, using a standard test soil. The test soil is easy to make up and use. The results show the over-all effectiveness of machine, operator, and detergent.

These simple tests are tools to be used by the sanitary inspector in his routine inspection work and by the restaurant operator in evaluating his detergents.

Sanitation Accomplishments

in

Local Health Departments

By L. M. FISHER, Dr.P.H.

Administrators of local health units, State and Federal health authorities, appropriating bodies, organized groups of citizens interested in the progress of public health, and ordinary taxpayers are all at some time concerned with the quality of the services performed by local health departments. In regard to sanitation services, they ask specifically: How many sanitation workers are needed to do the sanitation work in a local health department? What qualifications should these workers have?

It is believed that the studies in sanitation administration conducted by the Engineering Section Project, American Public Health Association, with funds provided through a research grant from the Public Health Service, are providing answers, at least in part, to these questions. These studies also suggest an objective method for evaluating sanitation programs in regard to adequacy of staff and general over-all efficiency.

Forty-two local health departments throughout the country participated in these studies (1-4). Each health department supplied factual data on health department personnel

and time data. Some of these data are presented and analyzed here.

Recording Methods

The environmental sanitation personnel of each participating health department recorded every activity requiring 5 minutes or more and the time required in minutes. Each activity was assigned two code numbers. One number indicated the kind of activity, such as a written inspection, a sample collection, a field trip, or a field visit; the other indicated the program in which the activity was carried on, such as food sanitation, milk sanitation, water, or sewerage (18 programs in all).

The same previously prepared code was used by all personnel, and the code numbers were checked by the health department's supervisor of sanitation. The daily activity reports were reviewed and edited by the same person throughout the study.

The daily reporting was carried out usually for 1 week, 3 weeks were skipped, and the reporting resumed for another week. The average time of participation by a health department was about 10 weeks, and the average number of men participating in the study was 370.

Field data were collected through November 1951. For each activity reported on the daily activity reports, an electrical machine accounting card was punched. Approximately 18 cards were punched for each daily activity re-

Dr. Fisher, an engineering field associate, was director of the Engineering Section Project of the American Public Health Association. This paper was read at the twenty-first annual meeting of the Southern Branch of the American Public Health Association, Baltimore, Md., April 17, 1952.

port, resulting in a total of approximately 250,000 cards reporting some 8 million minutes of time. This gave an average length of time for each activity of about 33 minutes. The punching of the cards received for the first quarter of 1951 was verified. Because of the small number of punching errors found, verification of cards subsequently punched was omitted. This cut the processing expense approximately in half. The accuracy of the unverified punching was deemed sufficient for our purposes. The total time punched for a given health department was usually within 5 percent of the figure called for by the official workday.

Evaluation of Services

Although it is generally accepted among public health workers that high-quality work is done by well-trained men, it seems to have been assumed in some quarters in the field of sanitation that anyone can make sanitary inspections. Many health officers have been obliged to accept the assignment of inadequately trained men because of the difficulty of showing that competently trained sanitarians accomplish more than persons less adequately trained. Furthermore, there is lack of agreement regarding the number of trained men needed to do a "good" job.

One of the chief obstacles in answering these questions has been the difficulty of determining when a job is well done. An approach to the solution of the problem of evaluating sanitation services is the use of milk sanitation ratings. If one accepts the thesis that a local health department has done a good job in milk sanitation when it attains a rating of 90 percent or better, using the formula contained in the sanitation evaluation schedule (5), a basis is provided for studying, analyzing, and comparing characteristics of health departments.

The quality of milk sanitation work is periodically rated by State or Federal health authorities in areas where the standard milk ordinance is enforced. Results of such ratings are expressed numerically, according to the procedures recommended by the Public Health Service (6). Approximate uniformity in rating by State health department personnel is accomplished by the periodic checking of ratings made by the Public Health Service at

Comparison of groups of health departments, based on over-all milk sanitation ratings

Characteristics	Upper third	Middle third	Lower third
Median rating-----	91.2	87.6	79.2
Minutes of sanitation services per capita per year-----	9.63	8.38	7.43
Percent of sanitation workers who were college graduates-----	35	35	28
Percent of units directed by masters of public health-----	67	44	33
Average educational ratings of men-----	13	13	13
Average educational ratings of supervisors-----	27	25	25
Percent of time in field-----	42	37	31
Percent of time in preparation-----	58	63	66

¹ Graduation from high school and the completion of 1 year of college work.

² Graduation from college and completion of 1 year of postgraduate study for which an advanced degree was awarded.

³ Graduation from high school and completion of 3 years of college work.

places selected at random against ratings made similarly and at the same time by State personnel.

The sanitation evaluation schedule provides a formula for combining the percentage of milk pasteurized, the rating of retail raw milk, the rating of raw milk sold to pasteurization plants, and the rating of pasteurization plants into a single over-all rating. This rating was used in the present study to divide 27 health departments operating under the standard milk ordinance into three groups: upper, middle, and lower thirds (see table).

The ratings for the three groups ranged from 97.5 to 67.8. All nine of the health departments in group 1 (the upper third) had over-all ratings of 90 or better; the average was 92.4, and the median was 91.2. The average for group 2 (the middle third) was 86.7, and the median was 87.6. Similar figures for group 3 (the lower third) were 78.8 and 79.2, 12 points below group 1.

Analysis of Characteristics

These three groups were studied to discover characteristics which might have a bearing

upon the quality of accomplishments. The principal characteristics investigated included time spent on general sanitation services, kind of leadership provided, educational qualifications of personnel, numerical adequacy of personnel, and activities which might reflect efficiency of effort.

The ability to make an adequate number of inspections is an important factor in maintaining sanitation at high levels. Therefore, the groups were compared with respect to the number of minutes of general sanitation services per capita per year provided. It was found that group 1 devoted more time to the whole field of sanitation than did groups 2 or 3, the average figures for the groups being 9.6, 8.3, and 7.4; respectively. The average for the upper third corresponds approximately to one sanitation worker serving 12,000 people, working 8 hours a day, 5 days a week, allowing 15 days' leave.

With respect to the qualifications of the health officer, it was found that 67 percent of those in group 1 had either a master or doctor of public health degree; 44 percent in group 2 and 33 percent in group 3 had such degrees.

The educational ratings of the supervisors of sanitation were 7 for group 1 and 5 for groups 2 and 3, according to the arbitrary scale set up for this study (see table).

There were seven engineers supervising sanitation in group 1 and three in group 3.

The percentages of college graduates among the sanitation workers in the three groups were 35 percent in group 1, 35 percent in group 2, and 28 percent in group 3.

The educational rating of the men was about the same for each group—approximately 3 (see table). The fact that there was no sharper differentiation in educational ratings for sanitation workers in the three groups may have been due to the fact that our method for determining educational ratings did not give any more credit, for example, for completion of several short courses, each of several months' duration, over a period of 10 years of service than for completion of a 3-day course during the first 6 months of service. This is an obvious weakness in our method.

Figures which may indicate efficiency of personnel are shown in the last two items of the table. For all sanitation programs for which

figures were reported in the time study, group 1 devoted 42 percent of its time to field work, compared with 34 percent for group 3, and took only 58 percent of its time to prepare for field work, compared with 66 percent for group 3.

Food Sanitation Ratings

It did not seem profitable to make a similar study based on food sanitation ratings (7) because only 16 health departments reported these ratings. However, a comparison of health departments attaining a rating of 85 percent or more with those attaining a rating of less than 85 percent showed that the first group had a higher percentage of college graduates than the second group and that the educational ratings of the sanitation workers and the sanitation supervisors were higher for the first group. The comparison also revealed that a larger percentage of the health departments attaining an 85-percent or higher rating were supervised by engineers than those in the lower group and that the upper group provided more minutes of general sanitation services per capita than the lower group. In addition, the average age of the worker was lower for the first group than for the second group.

Sanitation Ratings

Many who have followed the history of milk sanitation ratings closely are convinced that this rating system is useful for measuring the quality of milk sanitation. It is being used increasingly to judge the quality of milk coming from distant sources for local consumption, and is playing an increasingly important part in the interstate shipment of milk (8). These ratings make it possible to put milk sanitation discussions on a scientific and factual basis. The need for establishing such ratings in other fields of sanitation seems highly important.

In establishing sanitation ratings, a sound public health reason should be stated for every sanitary requirement, and there should be a reasonably accurate method by which a qualified person can determine when satisfactory compliance has been attained. When satisfactory compliance as reported by local personnel

checks approximately with compliance as understood by regional or national personnel, the development of a standard is begun. If the degree of attainment can be expressed in figures, there is evidence that the problem has been well analyzed. Evaluation of a program in general terms, such as excellent, good, fair, poor, or satisfactory, indicates that our knowledge is not well systematized, and such evaluation is of less value since what one person may consider to be good another may consider only fair or even poor. Even when ratings are expressed in figures, however, we must not attempt to make too fine distinctions. For some time yet, until all our standards are well defined and their use widely understood, we must be content to deal in numerical approximations.

In this study we believe we see the beginnings of processes which will make it possible to support with actual statistics conclusions based upon judgment and experience. It seems evident that in order that this may be done more effectively it is necessary to establish ratings in other fields of sanitation such as those developed for milk and food sanitation.

Use of the over-all milk sanitation rating as a tool for evaluating sanitation programs must be made cautiously. Experience in the use of this tool still needs to be developed. It should not be used, for example, to compare health departments operating under the standard milk ordinance with those not operating under it. Such a comparison would be unfair, since the two classes of health departments are not on the same basis.

It should not be used to compare individual health departments with each other, but it should be further tested in investigating groups of health departments in order to see whether trends which are indicated in this study will continue when larger groups are studied and also to ascertain whether other differences may be noted between groups.

Only recent ratings should be used, since the quality of health department personnel is never static; it either improves or deteriorates.

Summary

1. Comparison is made of certain characteristics of health departments attaining high milk

sanitation ratings with the same characteristics of departments attaining lower ratings. In general, the health departments having high ratings showed more time devoted to sanitation services, higher educational ratings of supervisors, more time spent on field work, and less time spent in preparation for field work than those having lower ratings.

2. The differences noted seem to set a pattern which suggests the need for more extensive study of the over-all milk sanitation rating, described in the sanitation evaluation schedule, as a tool for differentiating between efficient, well-staffed health departments and less efficient ones.

3. The development of additional standards in other fields of sanitation is urged in order that the effectiveness of sanitation programs may be measured.

ACKNOWLEDGMENT

Acknowledgment is made of the contributions of the sanitation personnel in the cooperating health departments and of the staff work performed by the Research Guidance Committee, American Public Health Association.

Hospital Beds for Tuberculosis

Tuberculosis control workers in many communities are daily confronted by the problem of long waiting lists for admission to tuberculosis hospitals and repeatedly emphasize the hardships resulting from the extreme shortage of tuberculosis hospital facilities. At times this situation has forced the adoption of unrealistic admission and discharge policies, to the general detriment of the public health program.

According to current State survey data, 39,000 tuberculosis hospital beds are still needed. However, this estimate is based on a minimum standard of 2.5 beds per annual death from the disease. This standard, established several years ago for want of a better yardstick, is no longer adequate, according to present opinion. With progressive improvement in treatment, fewer tuberculosis patients are dying of the disease. Therefore, for isolation treatment in hospitals, for aftercare, and for rehabilitation, we will probably continue to require more, not fewer, beds for some time to come.

Survey and Construction

With the passage of the Hospital Survey and Construction (Hill-Burton) Act of 1946, the country was provided with a systematic nation-wide hospital construction program utilizing financial aid from the Federal Government.

The program first aims to assist States in determining their needs for hospital and health facilities and in planning for the provision of needed facilities. Second, it assists the States in carrying out these plans by providing financial aid for the construction of needed hospitals and other health facilities.

Until now the emphasis has been upon the

This material — and the frontispiece — was prepared by the Division of Hospital Facilities of the Bureau of Medical Services, Public Health Service.

construction of general hospitals and health centers. The present situation in hospital construction was summarized in *Public Health Reports* for March 1952, pages 312-315. A review of State plan statistics for 1948 through 1951 appears in Public Health Service Publication No. 171 under the title, "Hospital Beds in the United States, 1951."

Only 3 percent of the 1,712 projects approved as of the end of 1951 were for tuberculosis facilities, providing less than 5,600 beds (see frontispiece). Since the Hospital Survey and Construction Act applies with equal force to tuberculosis facilities, it provides an excellent opportunity for material advances in tuberculosis control wherever the need exists. Financial assistance for construction is available to the States and Territories in meeting this costly phase of tuberculosis control. Local tuberculosis hospitalization needs should be made known to State hospital planning agencies, advisory councils, and the communities at large.

Tuberculosis Units in General Hospitals

The need to include adequate accommodations in general hospitals for the care of tuberculous patients has been recognized for many years. Tuberculosis services are being integrated with general hospitals for purposes of providing centralized services and medical care. In some instances this includes the common use of facilities, medical consultants, and other selected personnel for improved patient service and for education. Special tuberculosis hospitals and sanatoriums, integrated with general hospital services, are, of course, still needed in many areas. To help alleviate the shortage of tuberculosis beds, consideration should be given to including beds for tuberculosis patients in general hospitals. Past experience has shown this to be a highly desirable practice, and several States have adopted it in their plans for future hospital construction.

The Detroit-Windsor Air Pollution Study

The dramatic Donora disaster of 1948 brought renewed attention to atmospheric contamination and its effects on health conditions. In several sections of the country significant studies and extensive control programs are now under way.

Some of these were reported upon during the 1952 Industrial Health Conference in Cincinnati, Ohio, April 19-26. The Detroit-Windsor air pollution study—an integrated project with industrial, local, State, national, and international participation—was the subject of a symposium on April 22 jointly sponsored by the American Conference of Governmental Industrial Hygienists and the American Industrial Hygiene Association. Public Health Reports presents here, in brief, the six major papers.

Objectives of the Detroit-Windsor Air Pollution Study

PHR The International Joint Commission of the United States and Canada was established by treaty in 1909.

In article IX of the treaty, the Commission is given legal authority to study atmospheric pollution problems along the common frontier between the United States and Canada.

The Commission itself is not authorized to pass legislation, but it is required to make a joint report of every investigation with recommendations to both governments, who may

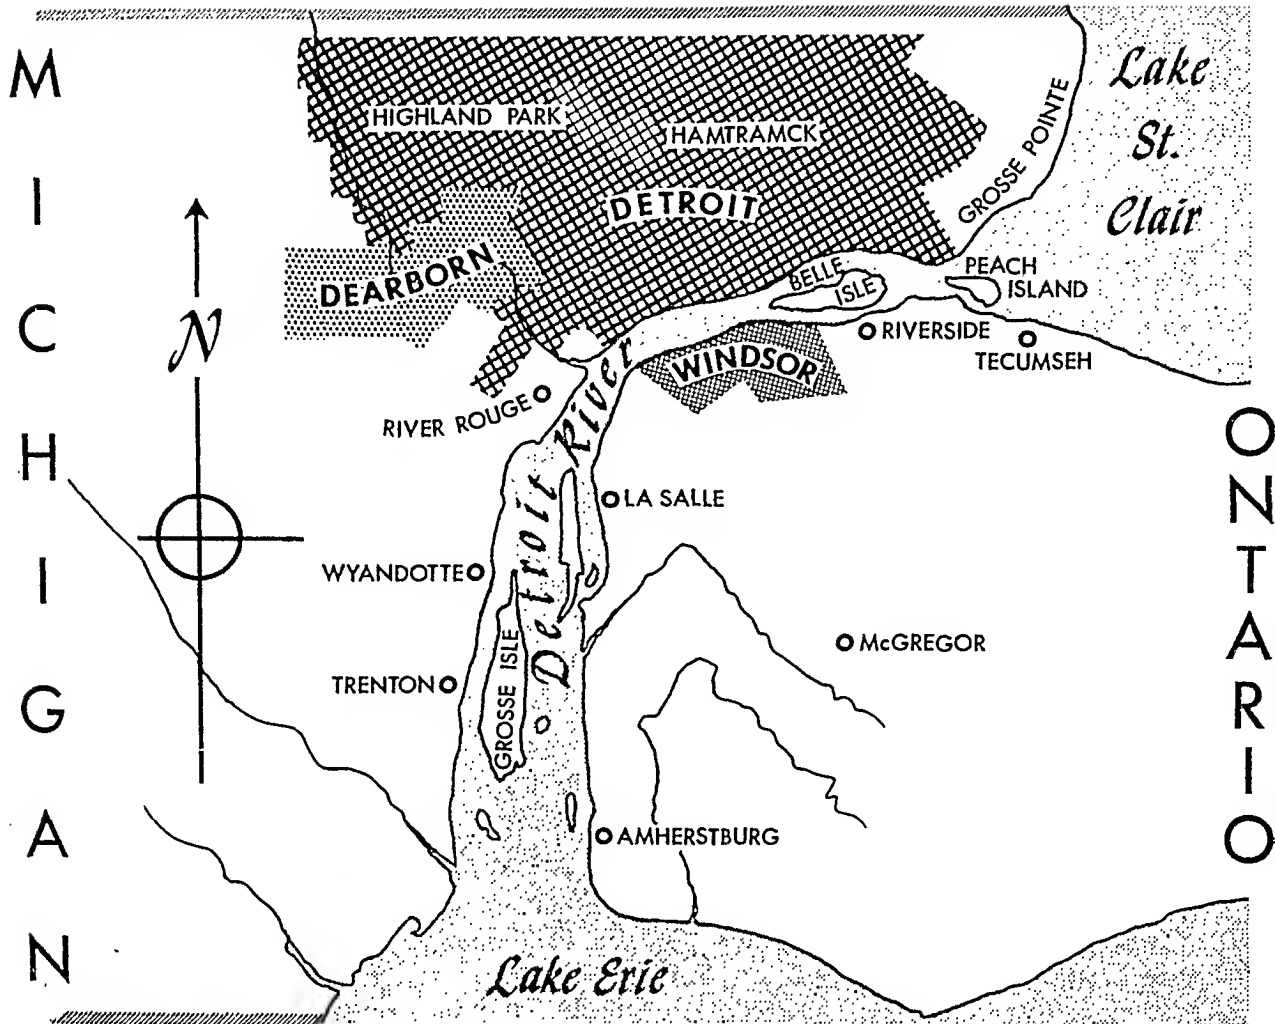

then act upon the recommendations, giving them the force of law.

As a result of complaints from Detroit, Mich., and Windsor, Ont., on both sides of the international boundary (the Detroit River), the United States and Canada in 1949 presented a joint reference to the International Commission, stating that the air in the vicinity of the two cities was polluted by smoke, soot, and fly ash discharged from vessels passing through the river. The joint reference requested the Commission to recommend remedial measures which would be economic and sanitary and to make a decision as to who would bear the cost.

The International Joint Commission established a Technical Advisory Board on Air Pollution, composed of three representatives from each government. The purpose of the board is to give technical direction to field work, to plan the studies on both sides of the boundary, to review the findings periodically, to discuss the significance of the data accumulated, and to make recommendations to the Commission. The board held its first meeting on May 12, 1949, at Windsor.

Although the joint reference outlined the

By George D. Clayton, B.S., sanitary engineer with the Division of Occupational Health of the Public Health Service, and chairman of the American Section, Technical Advisory Board on Air Pollution of the International Joint Commission of the United States and Canada.

The area of the air pollution study

scope of the study, it did not define its area, except for providing that it include the entire length of the Detroit River. The Technical Advisory Board decided that the boundary would stretch from Peach Island at the north end of the river to Grosse Isle at the south end, extending 15 miles inland on each side of the river.

Early in the planning, it became apparent that sufficient funds to conduct the investigations would not be forthcoming from the national governments. It was therefore necessary and desirable to obtain the cooperation of those agencies within the community which are responsible for the health and welfare of the people. Various State, Provincial, local, and national organizations, including the CIO and the AFL, have thus been approached.

Advisory boards of leaders in the engineering

and medical fields have been organized to assist in planning, guiding, and promoting the study. Many conferences have also been held with city officials.

Five objectives have been established for the Detroit-Windsor air pollution study.

Objective 1

Under the first objective—determination of sources, nature, and amounts of atmospheric contaminants resulting from combustion of fuels—the amount of pollution from fuel combustion of vessels, railroads, and domestic, industrial, and automotive sources will be ascertained.

The Ringelmann chart for estimating the intensity of smoke and the American Society of Mechanical Engineers code "Example Sections

for Smoke Regulation Ordinance" were adopted as standard.

One of the foremost problems for study is that of smoke emissions from vessels. For many years, the two cities have had smoke ordinances which were efficiently enforced by their smoke abatement departments, but no authority existed over vessels plying the international waters of the Detroit River. After several months of investigation, the data were presented to the Lake Carriers and Dominion Marine Associations, who joined forces in appointing a committee of combustion experts known as the Great Lakes Air Pollution Abatement Program Engineering Advisory Committee.

One phase of the committee's work was the study of the firing behavior of a boiler which had been removed from a vessel. As a result of this study, methods were perfected for the reduction of smoke to within acceptable limits for this type of boiler. Fuel specifications have also been established, and an educational program has been initiated.

Objective 2

To achieve the second objective—determination of sources, nature, and amounts of atmospheric contaminants resulting from industrial processes—it will be necessary to obtain mass emission rates from industrial stacks from which toxic materials and other contaminants are discharged into the atmosphere.

The Technical Advisory Board requested the division of industrial health, Michigan Department of Health, to obtain data from industry within the study area outside Detroit's city limits. Within the city limits, the bureau of industrial hygiene of the Detroit Department of Health was requested to assume similar responsibility. Because of the magnitude of the task, industry was requested to supply data on its own stack emissions. The excellent community spirit prevailing in Detroit and Windsor was shown by the support which industry has given to the study.

The larger participating industries were interested in acquiring more knowledge on the sampling and analysis of stack effluents. To meet this demand, a semester course of 18 lectures was established at the University of Michigan.

Objective 3

The third phase of the investigation—determination of effects of meteorological factors in the areas on the dissemination and diffusion of atmospheric contaminants—was undertaken with the cooperation of the weather bureaus of the United States and Canada and by personnel employed with funds provided by the United States Department of State and the Canadian Department of Internal Affairs.

A series of stations for sampling the atmosphere for solid and gaseous contaminants has been established in the study area, and the data from these samples are to be correlated by the weather bureaus. This correlation of data will indicate the diffusion rates due to meteorological factors as well as to the influence of temperature inversions on atmospheric contaminant concentrations. The data will also be used in studying the effects on health, safety, vegetation, and economy.

Objective 4

The determination of the effect of atmospheric contaminants upon health, vegetation, safety, and economy is probably the most difficult and time-consuming of all the objectives.

Because of the health implications posed by such acute incidents as occurred in Donora, there is great need to study the chronic, or long-range, effects of air contaminants on health. This is being undertaken jointly by the Public Health Service, the Canadian Department of National Health, and the Detroit City Health Department.

A more obvious problem is evaluation of the effects of atmospheric contaminants on vegetation, which is evident in the stunting of growth, loss of vigor, and reduction in crop yield. Air pollutants also present a threat to a community's civic beauty as well as to the prosperity of its outlying area. The technical board will request the assistance of a well-qualified organization to undertake this phase of the study.

There is need also to consider the effect of atmospheric pollution on safety. Studies will be made to determine what effects, if any, concentrations of various contaminants have upon aviation, automotive, and pedestrian safety. Appropriate organizations will be requested to

participate in studying the effects of air pollutants on aviation safety. This investigation will also include a study of the economic factors involved in air pollution and its effect on closed airports. The United States Weather Bureau and members of the technical board will cooperate in the undertaking of this study.

Objective 5

The last objective will be the determination of what controls are necessary, their cost, and by whom the cost should be borne.

Smoke is the only air contaminant for which workable data are available. Acceptable standards have been established for smoke emissions. Moreover, much research has been done on the control of smoke, permitting a fairly accurate survey of the cost of control procedures necessary to control smoke emissions within permissible limits. This is not true of other atmospheric pollutants. Data on standards for the emission of toxic gases and particulate matter into the atmosphere are insufficient.

During the investigative phase of the air pollution study, no attempt will be made to establish definite limits for the emission of toxic materials into the atmosphere surrounding industrial plants. No attempt will be made to establish limits for toxic materials found in community atmospheres. The study will seek to determine the effects of each individual contaminant, its relationship to other contaminants, and the practicability of certain control procedures. Only after careful review of all available information obtained during the course of the investigation will any attempt be made to recommend control measures for alleviating the atmospheric pollution problem.

Statistical Analyses in Air Pollution Studies

Air pollution can be studied successfully only when a wide variety of approaches is employed. In contrast to strictly experimental work where most environmental conditions are controlled, statistical analyses of air pollution

must deal with phenomena upon which the influence of many important factors is unknown.

Experimental animals in a laboratory can be kept in a relatively stable environment while the magnitude and duration of exposure are varied. But the composition and environment of human populations can never be maintained at the same level. Although people may be exposed to similar atmospheric contaminants, they live and work under diverse conditions. Chemical substances in the air are found in complex mixtures.

The statistical approach to studying uncontrolled phenomena offers the best hope of finding solutions. To be of greatest assistance on an air pollution study, the statistician should be a member of the research team in the planning stages.

Design of the Experiment

In any investigation, the objectives cannot be fully developed until certain facts about the community are known. In the Detroit-Windsor study, maps were available in the office of the city assessor, showing the ownership and boundaries of all industrial properties in Detroit. City air pollution inspectors were assigned throughout the city to determine from the assessor's maps which plants in their districts were contributing to air pollution.

Industrial plants were classified by type of smoke emission—active and inactive solids and active gases—and were then divided into heavy or minor pollution classifications. This information was transferred in symbol form to census tract maps of Detroit. It was thus possible at the onset of the study to visualize where the atmosphere was being contaminated and with what type of contaminant. Additional information was obtained from the public utility company, from a newspaper, and from regional planning maps.

The biological phase of an air pollution study involves the delimitation of socioeconomic areas. Basic data for this objective must be as-

By H. P. Brinton, Ph.D., and W. M. Gafaeer, D.Sc., Division of Occupational Health, Bureau of State Services, Public Health Service.

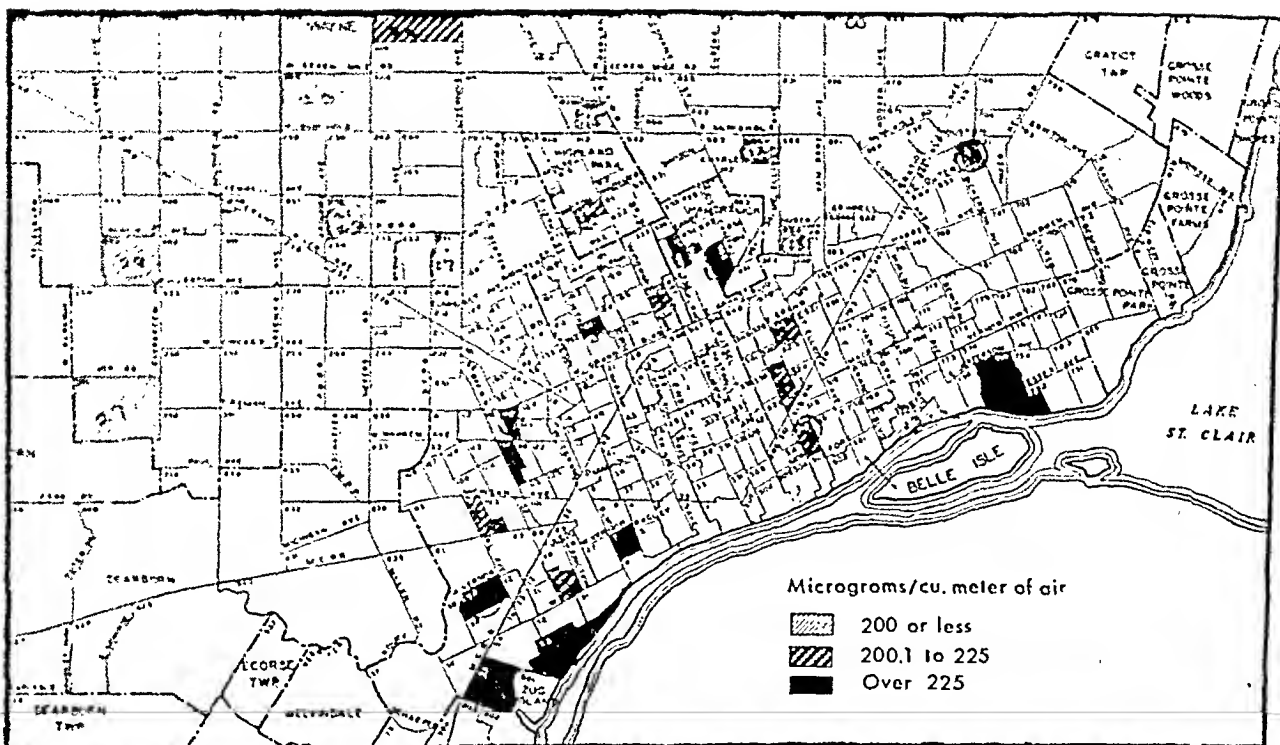

Figure 1. Census tract maps of Detroit are used throughout the air pollution study. This one shows the median weights (in micrograms per cubic meter of air) of total particulate matter based on air samples collected in selected census tracts in the Detroit area for the period May 7 through June 17, 1951.

sembled from a variety of sources, a task well suited to the statistician. In the Detroit-Windsor study, census tract information was sought from the United States Bureau of the Census on such topics as the 1950 count of population, 1940 census data for percent of nonwhite population, percent of foreign-born population, median years of schooling, percent of homes with mechanical refrigeration, and percent of owner-occupied homes.

A local sample survey made in 1946 provided economic ratings by census tract. The Council of Social Agencies furnished current data on relief cases, aid to dependent children, and old-age assistance. The juvenile court furnished data on the residence of youthful offenders. The interracial commission estimated changes in the proportion of Negroes since the 1940 census. The health department prepared information on vital statistics—total death rates and infant and tuberculosis death rates. Utilizing such information, the statistician prepared census tract maps, shading the variations within the city.

Figure 1 is an example of a census tract map used to pinpoint the amounts of total particulate matter collected in selected areas.

Once the sources of pollution have been spotted and the socioeconomic areas delimited, the groundwork for intelligent planning has been laid.

Operation of the Study

In the active phase of the study, the tasks of the statistician will multiply rapidly. Air-sampling stations should be located with regard to the adjacent human populations. The maps showing emission sources and classifying census tracts by socioeconomic status are needed to locate air-sampling stations. Census tracts should be grouped by pairs having relatively similar socioeconomic status but different amounts of air pollution. Since it was practicable to operate only a certain number of sampling stations, they were distributed on a random geographic basis among the approved census tracts.

An equally helpful study would be a statistical investigation of the health of people in sam-

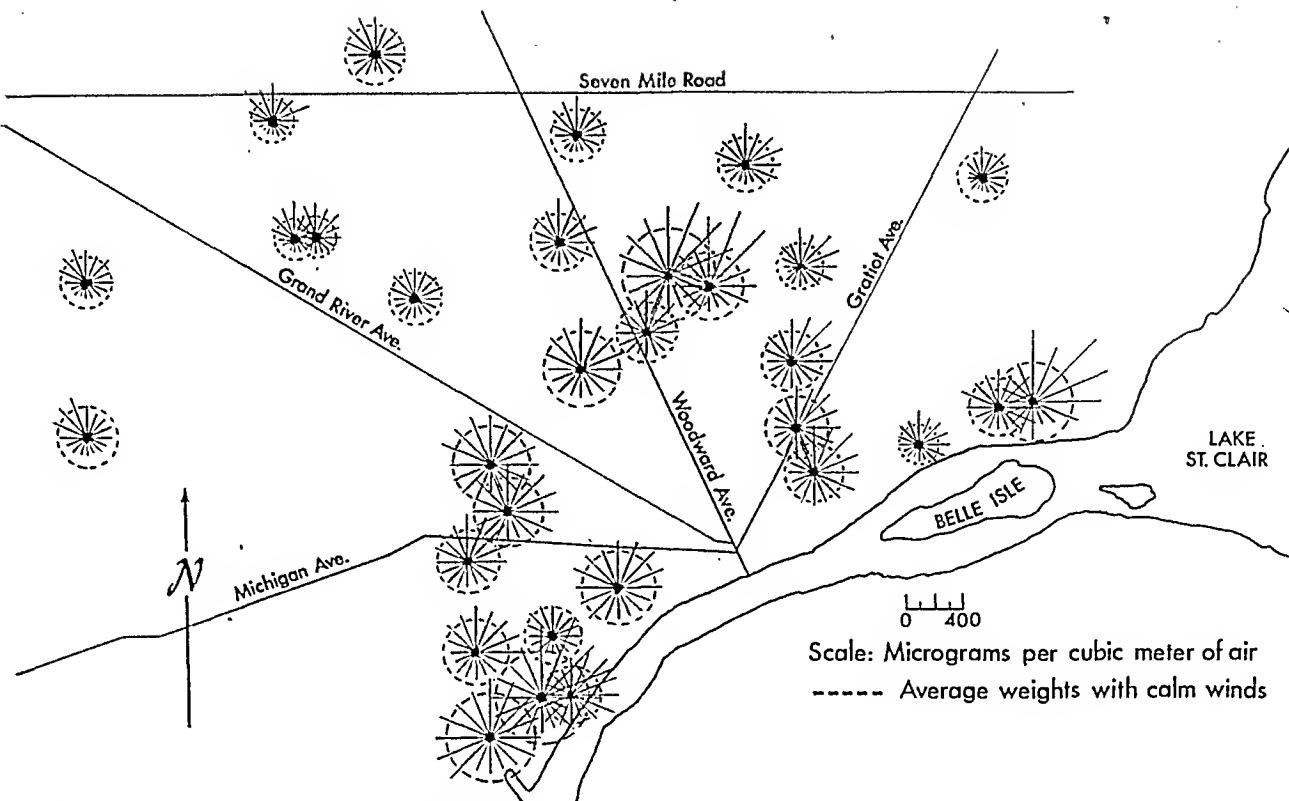

Figure 2. The above map of Detroit shows average weights (in micrograms per cubic meter of air) of total particulate matter according to wind direction for each of 31 sampling stations, based on daily air samples collected in the Detroit area, May 7 through June 17, 1951.

ple areas. Such a study might include a continuing record of the sickness experience of selected groups subjected to varying degrees of air contamination. Because of the infrequent occurrence of many diseases possibly related to air pollution, selection of the sample size is of major importance. The unit chosen for sampling might be a random selection of families in a designated census tract or in selected areas within the tract.

In planning the number of interviewers, estimates are needed on the average daily number of home visits to be expected of each worker. The time interval between interviews has been found to have a marked influence on the morbidity rates obtained. Field surveys of morbidity are but one of many possible means for the evaluation of health conditions. The statistician can assist in devising better and less costly methods for use of the other sources.

Analysis and Presentation of Findings

The validity of findings from any air pollution study will depend upon a comprehensive

statistical analysis of the data. Such analysis should partially answer the following questions: Which areas are more heavily polluted in terms of specific contaminants? How does the concentration of various contaminants in different areas vary with changing weather? Is there a common behavior pattern of the specific contaminants? Is there any over-all measure of air pollution to use as an index in ranking different areas in terms of average air pollution?

The statistician will select appropriate descriptive constants to facilitate comparisons among sampling stations. The medians may be used to represent an average value of a given contaminant at different stations and to rank the stations with respect to average concentration of the contaminant. Since sample weights represent average values of the contaminant for time intervals of equal length, the median may be considered the concentration of the contaminant which was equalled or exceeded in the atmosphere during half of the period under investigation.

The degree of concentration at the various

stations can also be measured by selecting a given concentration value and determining the proportion of sample values which equal or exceed it. This approach can supplement the information given by the median value. By fixing the concentration values at a relatively high level, heavily concentrated areas can be identified.

To investigate the relationship between weather and air pollution, the day-by-day weights of total particulate matter for one station and the average daily weights for all stations may be plotted in a time series. Weather conditions may be compared with these graphs, and strongly associated cyclic patterns may be observed.

The amount of contamination at a given air-sampling station can be related to the prevailing wind direction. To do this, multiply each daily weight of total particulate matter by the number of half-hours in the day when the given set of wind directions existed; sum up all days of the study period, and divide the sum by the total number of half-hours in the study period for this category of weather conditions. A map can then be prepared to show a sampling station with bars radiating from it in wind directions (see fig. 2). The length of each bar is proportional to the amount of particulate matter observed when the wind was blowing in a given direction.

Environmental Studies— General Area Sampling

PHR The population and industrial centers on both sides of the international boundary at the Detroit River may be considered as one area. A region of about 3 million inhabitants, it is one of North America's greatest concentrations of industry.

By Morris Katz, M.Sc., Ph.D., chairman, Canadian Section, Technical Advisory Board on Air Pollution, International Joint Commission.

Estimates place the annual domestic and industrial consumption of coal and solid fuels in the area at about 15 million tons on the United States side, and 650,000 tons on the Canadian side. Including the total from all sources, the coal consumed by vessel traffic on the Detroit River is conservatively estimated at 16 million tons. The average sulfur content of this fuel is at least 1.5 percent, and about 90 percent of the sulfur is released into the atmosphere during combustion. On this basis, approximately 430,000 tons of sulfur dioxide are emitted to the air annually from solid fuels alone, to be further augmented by the sulfur oxidation products from the combustion of natural gas, fuel oil, gasoline, and from such sources as metallurgical, chemical, and paper mill operations.

Among other toxic gaseous contaminants which have been found in this area are hydrogen sulfide, chlorine, oxides of nitrogen, and ammonia. Data obtained for these contaminants are meager in comparison with the continuous sulfur dioxide observations and, therefore, serve only to indicate the nature of the hazard.

The environmental studies have been designed to determine the maximum, minimum, and average pollution as influenced by meteorological and other factors over a sufficiently long period, and to evaluate their effects on health, economy, safety, and vegetation.

Obviously, such studies call for continuous observation and sampling techniques on an area basis. No adequate knowledge of diurnal variation, and of weekly, monthly, and yearly cycles of pollution can be obtained other than by the continuous sampling technique. A comprehensive picture of pollution is difficult to achieve by intermittent sampling methods. Meteorological factors, which cause great variations in pollution, are operative throughout the 24-hour day and fluctuate with the seasons. Environmental evaluations must be approached on this basis.

Sulfur Dioxide Pollution

The rise and fall of the level of sulfur dioxide in the air has been chosen as an index of gaseous pollution since the gas is one of the major contaminants in quantity in the area. Four con-

tinuous-test stations have been in operation in the Greater Windsor area where Thomas autometers have been located at three stations in the more heavily contaminated portion.

In view of the high persistence of winds from the north, northwest, west, and southwest directions, the sulfur dioxide observations at these stations are influenced by effluents from sources on both sides of the international boundary. The mean concentration at each autometer station has been calculated for every 30-minute period of the day. Peak concentrations over shorter time intervals have also been evaluated whenever such peaks have indicated unusual fluctuations in concentration. A comparison of the monthly means for 1951 indicates the existence of two seasonal peaks in the pollution load, occurring in the spring months of April and May, and in the late fall and early winter period.

The pollution load, as indicated by variations in intensity and frequency of sulfur dioxide fumigations, shows marked seasonal as well as diurnal trends.

Smog visitations of several days' duration have been noted during temperature inversion periods in the area. Highest frequency of occurrence was April, May, and July and from October to December. Relatively high peak concentrations of sulfur dioxide have been noted during such visitations.

In the light of what is known of pollution in other industrial areas, such peak concentrations, as well as the mean values, indicate more serious sulfur dioxide conditions in the Detroit River area than in such polluted zones as Los Angeles, Yonkers, N. Y., some of the industrial regions of Great Britain, and even the Trail, B. C., area, before the full employment of remedial measures. The possibility of a major disaster in the Detroit River area is rendered unlikely only on the grounds of its topography, but, with increasing industrialization, toxic levels of pollution are being built up to serious proportions.

Distribution of Suspended Particulate Matter

The zones of high, medium, and low pollution with reference to aerosol concentrations have been investigated by continuous high volume filtration units set up at 30 stations on

the United States side and 25 on the Canadian side of the boundary. These units sample the air at a rate of about 50 cubic feet per minute, and collect the aerosol contaminants on specially prepared pleated paper filters, which are changed every 24 hours. High concentrations of particulate matter usually coincide with periods of smog and relatively heavy sulfur dioxide fumigations.

Delineation of areas of heavy, moderate, and low pollution has been attempted on the basis of the mean and maximum concentrations of particulate contaminants from the continuous filtration data. In general, the most heavily polluted areas on the Canadian side lie close to the river. The areas of heavy pollution also lie within the zones which contain the major industrial operations. The areas of moderate to low pollution are located to the east and south of Windsor, with the lowest values of all shown by the sampling stations located at Tecumseh and McGregor, Ont. There is about a three-fold increase in mean concentration of particulate matter between the lowest and the most heavily polluted areas.

Distribution of Deposited Matter

The distribution of deposited matter, or dustfall, has been studied by analyses of data from 20 sampling sites in the greater Windsor area. In the heavily polluted area, the mean dustfall for all stations is about 92 tons per square mile per month. In the heavy to moderate pollution area, the mean dustfall is 53.9 tons per square mile per month, whereas in the moderate to low pollution zones the mean dustfall ranges from 42.7 to 35.9 tons per square mile per month. Here, as in the case of the suspended particulate matter, there is also a threefold increase in the pollution load in passing from the low to the heavily contaminated areas.

The average monthly dustfall pollution in the heavily contaminated area of Windsor is apparently greater than that reported recently for Chicago, Cincinnati, and Los Angeles, for Toronto, Canada, and for Pittsburgh.

There is a considerable difference in the composition of deposited matter and suspended matter in coal-burning areas. Particles which remain suspended in city air may consist of 85 percent by weight of tar and combustible or-

ganic matter, and only about 15 percent of ash, whereas deposited matter may contain upwards of 70 percent ash.

Nature of Suspended Particulate Matter

The chemical nature of the inorganic components of the complex aerosols in this environment has been studied by methods of X-ray diffraction and by spectrographic analysis. About 20 metallic elements have been identified in varying amounts. The most abundant are calcium, silicon, aluminum, and iron.

Public Health and Welfare

The air pollution disasters of the Mense valley in Belgium and at Donora, Pa., have shown conclusively that unrestricted and excessive contamination of the atmosphere under adverse meteorological and topographical conditions may lead to acute episodes involving sickness and death from respiratory and cardiovascular disorders. The chronic effects of air pollution are not so clearly defined; nevertheless, the frequent occurrence of eye irritation and the smog damage to vegetation in the Los Angeles area during temperature inversions illustrate that such influences are also present. The Donora report has stressed the significance of a synergistic effect in air pollution so that the combined influence of a number of toxic contaminants occurring simultaneously may be far greater than the additive effect of individual contaminants. The specific surface and adsorptive capacity of small aerosol particles for gases and vapors, the role of condensation nuclei, and the deposition of sulfuric acid mist and other compounds on such nuclei may affect the respiratory system in a manner entirely different from that of similar concentrations and durations of relatively pure toxicants.

Statistics and correlations on the increased deaths from respiratory disease during smog visitations in English industrial communities have been reported. The loss of sunshine and decrease in ultraviolet irradiation have been considered as contributing factors in the occurrence of deficiency diseases such as rickets. There is, as yet, little experimental work available on the effect of air pollutants on the health of humans and animals in the concentrations and under the environmental conditions ap-

proaching those of the atmosphere of cities and industrial areas. It was the consensus at the conclusion of the United States Technical Conference on Air Pollution of May 1950 that pollution with allergenic material of industrial origin is associated with a frequent and apparently increasing occurrence of acute and chronic disease, involving especially the respiratory tract and the skin.

Although there may be some disagreement among authorities as to the magnitude of the chronic effects of excessive air pollution on public health, nobody will deny the existence of adverse effects on public welfare. Huge economic losses have been sustained in city areas from the accelerated deterioration of buildings, structural materials, corrosion of metals, plant and household equipment, injuries to textiles and other fabrics, and excessive laundry bills. The frequent occurrence of smog in densely populated areas, accompanied by poor visibility, has caused serious and costly traffic dislocation at airports and on highways. In rural areas, gas damage may result in retardation and killing of crop plants and forest growth, and erosion and poisoning of soils.

Industry's Part In the Study

PHR It was expected that the information supplied, when evaluated, would give a fair picture of the combustion processes in the Detroit-Windsor area, and, at the same time, give a general idea of the degree of control now in effect. In addition, the evaluation should pinpoint a large portion of the potential sulfur sources.

Survey of Pollution Sources

The second major field of investigation was one which could become never-ending. It was covered by the request on the questionnaire that

By J. C. Radcliffe, M.Sc., supervisor, industrial health unit, Ford Motor Company, Dearborn, Mich.

"Companies operating plants which emit gases and solids into the atmosphere, other than ordinary products of combustion and fly ash, are to answer the following: (a) type of process; (b) list raw material used; (c) list finished products and approximate annual output; (d) nature of effluents; (e) height at which discharged; (f) methods adopted for reducing amount of this effluent."

A section for additional remarks was included, which undoubtedly was not wholly completed by many industries. Industry would be in an extremely enviable position if it had the answers to these questions. As it is, many industries have a long way to go in this direction, and the questionnaire results revealed an obvious lack of final data.

Coordination

It was indicated that the official agencies could perform some stack sampling along with type sampling in their areas. It was further indicated that the official agencies desired industry's cooperation wherever possible in a representative stack sampling program.

Thus, a separate technical committee was established through which official agencies and industry would coordinate techniques and sampling methods.

The next step was to develop agreement on the techniques and methods to be used in stack sampling. Various standard methods proposed by the American Society of Mechanical Engineers and other groups were reviewed. General rules were adopted on locating sampling points, measuring temperatures of stack gases, types of sampling equipment recommended, and types of materials to be analyzed.

Many representatives from industry were sent to the noncredit training lectures set up in 1951 with the University of Michigan extension service for instruction in the methods to be used in analyzing effluents from various stacks in the area. They have since begun their respective stack evaluations.

Stack Sampling

We have now passed beyond the initial mapping or planning stage. At present, most of the plants are approaching or are already in the sampling, evaluation, or correction phase of the

industrial study. We have reached the point of agreement on the order in which the stacks should be sampled. Normally, those operations which are thought to be prime contributors from a visual viewpoint are put first, and minor ones last.

In order to insure a common sampling procedure, most industries plan to have similar-sized holes put in all stacks so as to require only one basic type of sampling probe. Industrial planning and engineering departments are being contacted so that any new process exhaust stacks can be fitted in their design stages with the standard hole for stack sampling.

Care is being taken in the sampling program to note variations due to time of day, week, and point in the process. Sufficient grab samples (10 minutes to 1 hour) are obtained to determine maximum, minimum, and average conditions. In some instances, as on powerhouse stacks, it is necessary to obtain samples during both winter and summer.

The results we are getting are interpreted to indicate the degree of air pollution. Where high results are obtained, further corrective action is indicated.

From an industrial viewpoint, the most promising aspect of the entire industrial study of factors contributing to air pollution is not primarily the correction of existing conditions, but it is the designing and building of control devices to be incorporated into each new operation in the future. This type of control, planned before the foundation is laid for a building, in time will be of prime importance in controlling air pollution.

An invitation was extended to industry in the Detroit-Windsor area to discuss the proposed air pollution study to be conducted in that area. The meeting, held in September 1950, was attended by approximately 50 representatives of industry and technical personnel from official agencies.

As a start, industry's cooperation was requested in two major fields: the first, a survey of fuel and fuel-burning equipment used throughout the area; and the second, an inquiry into the sources of gases and solids discharged into the atmosphere in the area. To obtain the information it was decided that a questionnaire would be circulated to industrial plants.

factors include such aspects of housing as sanitation, overcrowding, physical recreation facilities and heating, man-made air contaminants, airborne disease-producing micro-organisms, pollens and other naturally occurring allergins, occupational exposures injurious to health, and weather. Also important is community sanitation—food, water, and insect and rodent control.

Once determined, socioeconomic influence in a given area remains fairly constant over a period of time. The ambient factors, such as man-made air contaminants, air bacteria, pollens, and weather must be measured accurately and continuously over the entire study period.

The collection of information on weather and on air contaminants is another phase of the air pollution study, but the data are collected so as to be directly applicable to the health study.

Preliminary Area Studies

It was apparent that a complex study of this nature involving a very large population group would have to be conducted according to sound statistical procedure. Samples of the area and population would have to be so selected that accumulated data could be treated by valid statistical analysis. Planning of the study was placed under the supervision of statisticians who would be responsible for the eventual analysis of the data. Under their direction, a thorough investigation was made to determine if satisfactory sample areas could be established with significant differences in respect to the several measurable environmental factors. In the Detroit-Windsor community it was possible to select a number of comparable sites for study. Examples are: high, medium, and low racial income groups in low and high pollution areas; low income racial groups occupying both poor and good housing. We feel that in the study of these groups informed consideration can be given to the significant social and economic factors of income, nutrition, medical care, race, age, and family sanitation practice.

The Pilot Health Study

The conduct of a comparative health study is extremely complex, tedious, and expensive. No prototype is available for guidance. The

Technical Advisory Board on Air Pollution of the International Joint Commission set up a subcommittee to plan the technical details of the study. The committee concluded that only a general plan could be evolved prior to actual field work. It was decided to develop the procedure for the general health study from a pilot study.

Organization of Community Resources

A successful health study is completely dependent upon the interest, cooperation, and support of the community. Medical and health agencies, industry, government, social agencies, the press, and the citizens must be made aware that a study is in progress. They must be convinced of its value before they will actively participate in or support it. To bring this about, a health advisory committee has been established for the Detroit-Windsor air pollution study. It is a large committee in which all phases of community life and institutions are represented.

Family Health Evaluation Techniques

The only direct method for establishing the comparative health status of population groups in the health study is through direct interview with a sufficient sample of family groups. Pairs of contrasting areas are being considered for study purposes. A sample of families in each area will be visited by a trained interviewer. At the first visit to the family the objectives of the study will be outlined and a fairly complete family history will be undertaken. Subsequent visits will be made monthly during the study to obtain detailed information on the family's health experience during the preceding month. The early phase of this work will primarily test sampling technique, forms, methods, and the response of cooperating families. During the latter phase, useful data will be collected which can be intercompared and evaluated by statistical methods.

Utilization of Existing Data

A substantial volume of pertinent health data is already being collected. The Detroit Health Department has excellent data on the geographic incidence of such diseases as tuberculosis, cancer, and pneumonia which may be

very informative if reconciled with the health area of this study. We have found that daily reports of sickness absenteeism from the medical departments of selected industries and the daily demand for substitute teachers in the public school system are useful indicators of sickness in the community. The records of physicians in selected areas of practice, allergists for example, may be especially pertinent. The city of Windsor has been conducting a general health study for some time among its residents.

Implementation of the Pilot Study

Even a pilot study of very limited scope is a time-consuming and expensive undertaking, apart from the collection of essential concur-

rent air pollution data. A pooling of contributions in staff and funds from the health services of the national governments, State, Provincial, and local health departments, research foundations, and community industry is necessary.

The conduct of a valid inquiry into the effect of air pollution on health is a formidable undertaking, requiring integration with concurrent environmental studies and consideration of socioeconomic factors. It must be a total study of the health status of the people of the community. It is hoped that the effect of several environmental and social factors on health will be determined at the same time. It is this hope that justifies the tremendous effort and expense the health study involves.

Clearinghouse on Morbidity Statistics Projects

A clearinghouse for current studies and surveys of morbidity has recently been established under the auspices of the Public Health Conference on Records and Statistics. The purpose of the clearinghouse is to help public health and medical workers locate specific data on diseases, injuries, and impairments, and to permit those who are planning new projects involving the measurement of illness to contact others who have undertaken similar tasks.

At regular intervals the clearinghouse will conduct a canvass of studies or surveys in progress. Lists of new projects to be released from time to time will contain brief outlines of the methods used and data to be collected. No information will be published, however, without the permission of those responsible for the project.

Inquiries about the clearinghouse may be directed to: Clearinghouse on Current Morbidity Statistics Projects, care of Division of Public Health Methods, Public Health Service, Federal Security Agency, Washington 25, D. C.

Have You an Idea?

Do you feel your ideas are too old? Perhaps. But those you have tested through the years may be new outside of your health community—and may be just what someone else needs. Share your ideas. Write us, and we will try to help.

—THE EDITORS

Operation Knoxville

TENNESSEE. Operation Knoxville is the first campaign of its kind to unite the entire resources of a community in seeking out, rehabilitating, and placing in employment the handicapped citizens of a locality.

Knox County, Tenn., where the rehabilitation campaign was launched last February, has some 1,500 known handicapped persons. If at least one-half of this group could be rehabilitated for employment, an estimated 250 families and 700 children would be removed from the public assistance rolls, thereby reducing municipal expenses far beyond the cost of rehabilitation.

Operation Knoxville was initially proposed by the Tennessee State director of vocational rehabilitation, who called an informal meeting of community leaders to discuss plans for rehabilitating the local handicapped population. Local residents and Federal consultants worked out a team approach for the screening and evaluation of rehabilitation cases. Committees were formed of industrial leaders, personnel directors, and representatives from labor unions, medical societies, vocational schools, and other educational facilities.

The Knoxville project has been successful—so much so that in Washington the Office of Defense

Mobilization has worked with the Office of Vocational Rehabilitation of the Federal Security Agency to develop and distribute informational materials about the project for use in radio addresses and public forums throughout the country. These materials have been sent to all State rehabilitation agencies.

Fountain Phi Betes

COLORADO. Courses designed especially for soda-fountain personnel are a special service open to all Colorado communities by the food-service and sanitation program of the State board for vocational education.

Two short courses are offered, each consisting of four 2-hour sessions. One is open only to experienced, employed personnel, and the other is for high school students working part-time at fountains.

Soda fountain dispensers are no longer called soda fountain "jerks"—this change-over to a self-respecting job designation is one of the early principles taught to the students of the courses.

Specific instruction covers: work routines, dispensing techniques, fountain formulas, tips on sandwich making, proper handling of eating utensils, methods of cleaning and using all fountain equipment, and when and how to use single service utensils.

Part-Time Teachers

ARIZONA. A plan for utilizing services of teachers on a part-time basis in expanding community health services is being put into action here. Elementary teachers with specialized training in health and physical education will disseminate, in their own localities, the latest information on public health to schools and various professional and service groups interested in better health programs. The plan was developed by the State Health Department in cooperation with Arizona State College at Tempe.

Laboratory Aid

BETHESDA, MD. Are you breaking or etching glass pipettes against the rims of glass jars in which they are placed in a disinfecting solution?

Try using a one-fourth-inch bore rubber tubing, which is standard equipment in any laboratory. Split it lengthwise, and cut it to fit around the jar rim. This effective protection against breakage and contamination was devised by a young medical biology technician, Walter S. Hunter, at the National Institutes of Health of the Public Health Service.

Needle Tubes

BROOKLYN, N. Y. Any laboratory can make its own sterilizing tubes for needles, thereby avoiding dulled needles and saving money, according to the Public Health Service Hospital at Manhattan Beach.

Take an ordinary test tube—this is an ideal way to use old, scratched, and etched tubes. Heat it sufficiently to indent a portion where a needle can be suspended. Judge the size of the test tube needed by the size and length of the needle—for a 1½-inch needle, a 120 x 13 mm. test tube is suggested.

Previously, the hospital laboratory used as a holder a test tube plugged with cotton in which the needle rested. But cotton fibers could be drawn into the blood stream by lodging within the hollow of the needle. To avoid this possibility, the problem of suspending the needle in a tube was presented to Ernest Battle, a medical technician in the laboratory. The result is not a new idea—there is a commercial tube available for approximately 25 cents.

The laboratory not only prepares its own supply of needle holders, keeping about 100 sterilized needles on hand at a time—it also maintains a stock of the tubes in the central supply room of the hospital.

Activities of Health Officers *in* Local Health Departments

By MARION FERGUSON, Ph.D., HARALD M. GRANING, M.D., M.P.H.,
and BESS A. CHENEY, M.A.

In his typical work week, the local health officer spends 2,538 minutes for 74 activity occurrences in 12 different health programs. Seventy-five percent of this average, or 1,896 minutes, involves medical judgment.

These figures are derived from information supplied by 186 physicians serving as health officers in local health departments throughout the United States, in a study undertaken to obtain information on the utilization of medical manpower in the public health field.

Critical shortages of manpower exist in public health—a field for which the preparation of professional workers requires a long time and in which the number of such workers is limited. The prospects are that the demands of civilian defense, the needs of the military services, and those of the Point IV technical assistance pro-

gram will further accentuate this shortage. Consideration of these factors made it worth while to ascertain, if possible, the programs and activities of physicians employed as local health officers and to learn something about the extent to which they felt they used medical judgment in performing those duties.

The techniques of activity analysis and time study have been used successfully in the field of public health for investigations into the work of various types of personnel, though only a few studies have been reported for health officers. In 1933, Charters (1) studied the duties of Ohio public health commissioners to provide the basis for the curriculum of a physician-training program. Dean (2), in 1935, analyzed the job of a rural health officer as one of the Brunswick-Greenville Health Administration Studies. Included was a distribution of the time of the health officer for a 10-month period.

Plan and Participation

The present study was planned to collect information concerning the range and frequency of activities of full-time health officers in local health departments serving jurisdictions of 50,000 to 500,000 populations within the continental United States.

Reports were received from 186 health officers, 51 percent of the 365 known to be employed on a full-time basis in all types of local health departments serving areas with such populations

Dr. Ferguson, chief of studies, Division of Public Health Nursing, Public Health Service, and Dr. Graning, regional medical director, Public Health Service, Federal Security Agency Region V, Chicago, were previously with the State and local health services branch, Division of State Grants. Miss Cheney is health advisor, Division of State Grants of the Bureau of State Services, Public Health Service.

A report on "Activities of Medical Administrators in State Health Departments," appeared in Public Health Reports, May 18, 1951, pp. 619-629.

(2). Health officers in 35 States participated in the study.

Length of Work Week

One hundred and six health officers reported a 5½-day week, 66 reported a 5-day week, 9 reported a 6-day week, and 4 reported some time on the seventh day. One participant became ill and reported only 3 days.

The length of the work day, Monday through Friday, ranged from 4 to 16 hours, with a median of 8 hours. The median time on Saturday was 4 hours.

Eighty-five of the respondents reported a work week of 40 to 48 hours, while 46 reported between 36 and 40 hours, and 21 between 48 and 52 hours. Twenty-five reported less than 36 hours, 8 reported between 52 and 60 hours, and one, serving a large local district, reported 77 hours.

The average length of work week for actual time reported was 42 hours and 18 minutes. Very little variation occurred in the average when the length of the working time was computed by size of population served, or by type of department.

Programs

A total time of 472,045 minutes was reported by the 186 local health officers for activities performed during the period of the study. This represented 13,749 occurrences of those activities, or a mean time of 34 minutes per occurrence.

The material reported was grouped into 20 types of programs. Nineteen of these were categorical and one, general, related to more than one program or to over-all administration. This group accounted for 39 percent of all time reported, and the first 10 programs accounted for 86 percent of the total time reported.

¹ Only 25 of the 13,749 entries, accounting for 1,025 minutes, could not be identified, an insignificant fraction of the time included in the study.

When the individual programs were arrayed in descending order according to the amount of time reported, there was a consistency in the relative rank of most of them, whether they were considered by size of population served, by type of department, by geographic

location, or by season. Over-all administrative problems, as reported under general, ranked first on all the distributions. Sanitation was second in all but local and State district health departments. Although the other programs were not as consistent, with but few

exceptions they tended to cluster within a comparatively narrow range. Medical care ranked from fourth to tenth place in the 20 possible distributions.

Activities

Activities reported were grouped under 26 headings. The first five activities represented 45 percent of the total time. The inclusion of the next five activities raised this to 70 percent.

For both programs and activities, the greatest variations from the array of the total time were found in the health departments which served the largest population, in State district health departments, and in the Great Plains and Rocky Mountain regions.

Relation of Activity to Program

No consistent pattern emerged in relating activities to programs. Only individual conferences and clinic participation represented as much as 10 percent of the total time. Direction and supervision required 6 percent of the total

When the activities were grouped by size of population, type of department, season, and geographic area and were arrayed in descending order according to the amount of time reported, none of them was consistently in first place. Clinic participation ranked first in 10 of 20 distributions, although it ranked second in total time. Individual conferences, first in total time, also ranked first in 6 distributions and ranged from second to fifth in the remaining 13.

time, varying from less than 1 percent in the cancer program to 19 percent in laboratory. About 2 percent of all time reported was listed for personnel, ranging from none in three programs—crippled children, industrial hygiene, disaster and emergency—to 6 percent in laboratory. Sixty-four percent of all time devoted to personnel was reported in the general program, but this activity represented only 3 percent of the general program time.

Program planning had an important place in the chronic disease and laboratory programs where it required 12 percent of the time for each, and in the dental program with 18 per-

Figure 1. Percent distribution by program of total time and of total time involving medical judgment reported by 186 local health officers for one week in 1950.

cent. However, all programs except training reported some time in this activity. Eighty-three percent of all time spent on budget and fiscal matters was allocated to the general program, representing 5 percent of the time in that program. In most of the specialized programs, little or no time was reported for this activity. Licensing and permits, with which was included authorization or commitment for hospital or

other care, took 14 percent of the time reported in the mental hygiene program, 5 percent in medical care, 4 percent in tuberculosis, but was unimportant in all the other programs. The general program included 93 percent of all time for correspondence, which represented 20 percent of the total time in that program. The remainder of the time for correspondence was scattered through the categorical programs in very small units.

The only program including a considerable amount of time for records and reports was public health statistics, in which this activity represented 26 percent of the time. Meetings attended represented only 4 percent of the total time, but it was an important activity in the cancer program, requiring 29 percent of the time. It also accounted for 10 percent of the time in the industrial hygiene program, 11 percent each in medical care and in training, 13 percent in chronic diseases, and 16 percent in the disaster and emergencies program.

Individual conferences, which represented the greatest amount of time for a single activity, ranged from 1 percent in the training program to 21 percent in sanitation. It made up 12 percent of time reported for medical care. Group conferences also took a good deal of time, from 2 percent in the venereal disease program to 22 percent in the dental and training programs. Field investigations were important activities only in communicable disease and in sanitation, where they represented 11 percent of the time, and in industrial hygiene, 17 percent. Evaluations and surveys accounted for 19 percent of the time in the public health statistics program but elsewhere required little time.

In eight categorical programs, clinic participation represented the highest percent of time, with more than 40 percent reported in infant and preschool, venereal disease, and maternity. Little time was reported for this activity elsewhere. Professional consultation appeared in an appreciable amount only in the communicable disease program, where it represented 9 percent of the time.

Medical Judgment

Of the 472,045 minutes accounted for by local health officers in this study, 352,575, or 75 per-

Figure 2. Percent distribution by activity of total time and of total time involving medical judgment reported by 186 local health officers for one week in 1950.

cent, were reported as spent in the performance of duties that in the opinion of the respondents involved medical judgment; 116,060, or 24 percent, were for duties that did not involve such judgment. No decision was indicated for the remaining 3,410 minutes, slightly less than 1 percent.

The mean time of 34 minutes per occurrence increased to 37 minutes when medical judgment was involved and decreased to 28 minutes when it was not involved.

No definition of medical judgment was attempted in preparing instructions for use in recording activities. It was believed that each health officer could best determine from his own professional background and his own evaluation of his activities which of his individual actions involved medical judgment.

The percent of time which involved medical judgment as reported by individual respondents ranged from 100 to 12 percent. Five of the 186 health officers reported that all their time involved medical judgment. One health officer indicated only 12 percent of the time he reported involved medical judgment. The median percent of time in which medical judgment was involved was 76. The middle 50 percent of the health officers reported that medical judgment was involved in their activities from 65 to 88 percent of the time.

Health officers in areas of 50,000 to 99,999 reported the highest percent (78) of time involving medical judgment. This decreased to 73 percent for the middle population group and to a low of 62 percent for the areas of 250,000 to 500,000. Apparently the volume of nonmedical administrative duties increased as the size of population in the area served increased.

The percent of time involving medical judgment (74 to 76) reported during each study period was quite consistent. The demands on the medical skills of the health officers seemed to be year-round demands rather than seasonal.

The amount of time reported as involving medical judgment varied with the type of department. The percent (68) of such time was somewhat lower for city-county units than for all types of departments as a whole, while it was slightly higher for local health districts (82 percent) and State districts (81 percent). The lower percent in the city-county units

Figure 3. Percent of local health officers participating in each program.

might be explained by the more complex non-medical administrative duties, although the difference was not great enough to be significant.

When the geographic location of the health department was considered, the percent of time reported as involving medical judgment did not vary appreciably among Federal Security Agency regions except for Region VII. The 55 percent reported for this area was considerably below the range of from 69 to 75 percent re-

ported for the rest of the country. In this region, the health departments reporting were city, city-county, and county departments and were in areas of 100,000 to 249,999 population.

For the various programs, the time reported as involving medical judgment ranged from 94 to 48 percent (fig. 1). Those in which 94 to 90 percent of the time was so reported were venereal disease, communicable disease, maternity, infant and preschool, tuberculosis, cancer, mental hygiene, and medical care. The smallest percents of time (70 to 48) were reported for the dental, public health statistics, general, industrial hygiene, and sanitation programs.

The amount of time reported as involving medical judgment varied considerably for the different activities (fig. 2). Clinic participation had the most time, 99 percent, reported as involving medical judgment. In only two other activities, professional consultation and talks given, did the time exceed 90 percent. The low was 24 percent for purchasing. Five other activities (community activity, enforcement of ordinances, personnel, budget and fiscal, and housekeeping) had 56 percent or less of the time so reported. Eighty-three percent of travel time was tabulated as involving medical judgment. Since this amount of travel time was spent reaching activities reported as involving medical judgment, these trips could not be delegated to nonmedical personnel.

Individual Respondents

Considerable variation occurred among the 186 health officers in the number of programs and the number of activities in which they reported participation during one work week.

One health officer reported time in only 4 programs while another reported time in all 20 used in the analysis. The median reported was 12, the interquartile range was from 9 to 15. Thirty health officers reported participation in 10 programs.

Every health officer reported participation in the general program. Next was the sanitation program, reported by 182 health officers. The two programs participated in by the fewest health officers were disaster and emergencies, and training (fig. 3).

The number of different activities in which

Figure 4. Percent of local health officers participating in each activity.

a health officer reported participation increased with the number of programs. One reported only 7 different types of activities in 7 programs while another reported 25 in 17 programs. Seventeen activities constituted the median, while the interquartile range was from 13 to 20. Each of 28 health officers reported participation in 18 different activities.

Correspondence as an activity was reported by 99 percent and individual conferences by 95 percent of the health officers, while teaching, housekeeping, and talks were reported by the fewest, 18, 30, 32 percent, respectively (fig. 4).

The patterns of participation of the individual respondents in both programs and activities were quite consistent with that of the total except for the largest population group and for State and local health districts.

Conclusions

The day-by-day schedules of a week in the official life of local health officers provided the list of programs and activities used in this study.

Although no special programs or activities can be specifically isolated for delegation to nonmedical administrative personnel, several types of activities within certain program areas might well be examined from this standpoint. Among these are eight activities, representing 33 percent of all time reported, in which no medical judgment was involved: telephone, records and reports, community activity, enforcement of ordinances, personnel, budget and fiscal, housekeeping and errands, and purchasing.

Obviously, some of these activities, such as community activity and enforcement of ordinances, are essential parts of the health officer's official duties, and even though the percent of time in which medical judgment is not involved is relatively large, they could not be delegated. In such activities as budget and fiscal matters, personnel, records and reports, it is possible that the time of the medically trained administrator might be reduced to that required for supervision only.

While the time saved by the health officer through delegating activities not involving medical judgment may not seem significant in

the course of a single working day, it is this time which must provide the margin for extending those activities and services which only the medically trained administrator can provide. With the prevailing shortages of such personnel and the increasing demands for these services both during times of emergency and future program expansion, it is urgent that those activities be identified which, under suitable circumstances, may be delegated to administrative or other personnel who are not medically trained.

Although the median is 76 percent, the range in percent of time in which medical judgment is involved is very wide. This raises the possibility that if further explorations of the extremes in the range could be undertaken, a more adequate basis for evaluation of the time in which medical judgment is involved might be attained.

Delegation of selected activities to responsible persons already in the local health departments, or to persons employed to carry on such activities, will not be easily accomplished and will require an open mind on the part of those charged with planning and administering the public health program. When the local health department has neither the trained nonmedical administrative personnel nor the funds available to provide such special assistants for the health officer, it still may be possible, through careful planning, to reassign some of these duties. Even in small health units, much responsibility can be given to a good clerical worker under the health officer's supervision.

State health departments can provide extremely valuable assistance in the orientation of the local health officer to the need for re-examination of his official responsibilities, in light of present-day conditions, and in the in-service training of his staff members to assume some of the duties mentioned.

There must be an awareness on the part of the health officer of the urgency of getting things done which only he can do and a willingness to permit others to assume such parts of his activities as can be safely delegated. As may easily be seen, there are problems in recruitment, training, supervision, and evaluation areas to be met and solved in saving the time of the health officer for those things he alone can do.

This challenge to public health can be met only through mutual understanding and cooperative action by all concerned, but its successful solution should serve to extend existing medical manpower resources and to make careers in public health increasingly desirable for physicians.

Maintenance Expenditures In Public Mental Hospitals

In Relation to General Revenues of States

A ratio commonly used to measure the cost of care a State provides for patients in its public mental hospitals is the amount of money spent annually for maintenance per patient. Although it is sometimes inferred that States with higher per patient maintenance ratios provide better care, variations in cost of living, in accounting practices with respect to what items are considered as "maintenance," and similar factors will affect to some degree the comparability of such statistics.

Most statements of financial ability of a State have centered around the per capita income

concept. However, there are many States where the revenue available for the support of mental hospitals comes from sources besides income or other taxes on individuals. The concept of per capita income, for example, excludes revenues collected by taxes on corporate income or real or personal property. The measure of a State's ability to pay for the cost of public mental hospital maintenance might more realistically be based on all its revenues and not merely on a part.

The data reported here show the degree of correlation which exists between a State's financial ability—as measured by its general revenues—and the amount of money provided for patient care. No attempt is made to determine whether the proportion of total revenue used for public maintenance of the mentally ill in a State is adequate or not since there are no avail-

Human Relations in Occupational Health

By DALE C. CAMERON, M.D., M.P.H.

Human relations are common, everyday experiences in our professional and personal lives. In fact, they are so familiar that all of us have pretty definite ideas about their importance and how they should be handled. I shall make no attempt to offer you new facts or findings based on recent studies, but we may be able to do some joint thinking as to the place of human relations in occupational health, for such problems frequently bring people to the medical department. I hope, too, we may obtain a clearer perspective of the ways in which we may approach these problems in our own professional activities.

It is probable that definitions of "occupational health" and "human relations" are unnecessary. However, I offer the following definitions in order that you may be certain of my meaning as I use these terms.

A good occupational health program is one carried out primarily for the benefit of the workers. It has as its objectives:

1. The assessment of a worker's physical and psychological assets, as well as his liabilities, to facilitate proper selection and placement.
2. The prevention of occupational and non-occupational illnesses.
3. The provision of treatment, the type and extent of which depends on the policy of the organization.
4. The fostering of a personal, physical,

mental, and social ability to work and enjoy life beyond the mere absence of disease or infirmity.

Manner vs. Matter

Human relations have to do with the nature of interpersonal contacts between individuals and groups of individuals—how people get along with each other.

That the manner in which these contacts are made has a bearing on the result has been too little appreciated. Yet, this bearing, in many cases, is as great as, if not greater than, the apparent topic or purpose of the exchange. We find this to be true, for example, in the experience of the person who habitually orders others to do his bidding, acts as though he has the weight of the world on his shoulders, fails to consider the personal needs of his subordinates, and neglects to acknowledge work well done. As a rule, such a person does not earn the confidence and cooperation of his fellow workers as much as another who makes the same requests, but pleasantly and considerately. The topic or purpose of the exchange may be identical, but the difference in manner and method of contact results in a different response. The second individual intuitively knows or has learned some of the principles of human relations and applies his knowledge, while the first either does not know or fails to practice what he does know.

Effect on Health

The recognition that human relations can, and do, exert a marked effect on health should

Dr. Cameron is chief of the cooperative health services branch, Division of Occupational Health of the Public Health Service. This paper was presented at the United States Navy Fourth Industrial Health Conference, Cincinnati, Ohio, April 20, 1952.

be a fundamental concept of every health program. It has an important bearing on the success with which plans are executed for the selection and placement of workers, the prevention of illness and absenteeism, the provision of medical care, and the fostering of health.

To assess properly the health effects of human relations in industry, let us first look at the sickness absenteeism problem. Figures based on limited studies in this country and in England indicate that about 30 percent of all sickness absenteeism is due to emotional disorders. Although we may not know exactly to what extent problems of interpersonal relations are causatively related to the emotional disturbances of a given individual, many studies indicate that they are often major factors. That these emotional disturbances, in turn, affect physical health and efficiency has been amply shown by developments in the field of psychosomatic medicine.

Much of the absence occasioned by emotional problems probably is due to poor human relations in and outside the work place. Other sickness absenteeism is also caused in part by poor human relations. The relatively high absence rates in groups suffering from poor supervision is striking (1). Many of the illnesses among industrial workers can be prevented or alleviated by good in-plant health services, but the problems of human relations cannot be cleared up by the dispensing of medicine, or by exhaust ventilation. Good human relations can be achieved only when everyone in the plant understands their importance and is sincerely motivated to improve relations with one another.

Our concern, then, is to try to improve the way in which we in occupational health departments deal with people, and the way they deal with us and with each other. This activity cannot be a unilateral effort on the part of the medical staff, for it also requires the combined skills of the personnel department, counselors, management, and labor. Only through such a team approach can each individual be helped to achieve more fully his own potential so that he may have a better opportunity to advance himself and to make greater contributions both as a worker and a citizen.

Implicit in the question of interpersonal relations is the need for proper understanding of attitudes and behavior and recognition of the fact that behavior just doesn't happen—there is a reason for the way people behave. Individuals simply do not divorce themselves from their personal, family, and community concerns and attitudes when they enter into the work place. Likewise, at the end of the business day, they do not automatically "shed" their job problems. Consequently, the health of workers is intimately related to the things that go on not only in the plant or business, but also in the home, the community, and the Nation.

Basic Human Needs

To approach the problem of human relations in occupational health, one must first recognize some of the basic human needs which most people bring with them to their jobs. They want to know what is going on in the plant and why things are done as they are. They want to know what their jobs are, what is expected of them, and where they stand in the organization. They hope to be treated in a considerate, predictable manner.

As they find their places in the plant, they expect a certain amount of recognition of their status in relation to experience, skill, and seniority. While speaking of recognition, one must not forget that most workers usually want some recognition of their job status from their families as well as from their fellow workers. Failure to get it may increase their demand for recognition at the plant.

Job satisfaction is very important to most workers. Some obtain it from the fabrication of products of fine craftsmanship. Others derive their major work satisfaction from the creation of new ideas, tools, processes, or procedures. Still others are unable to produce fine craftsmanship or new ideas, and the necessity to do so would threaten their job satisfaction and security. Such workers often are most satisfied with a relatively simple, repetitive type of operation. Particularly important in job satisfaction are the degree to which the job approaches the worker's own aspirations and the opportunity afforded to achieve them.

Pay, though important, is often assumed to

play a greater role than it actually does. In several studies, various types of job satisfaction have been rated as more important by the majority of workers. In general, it may be said that pay often assumes greater importance as the degree of job satisfaction declines.

Another important human need is that for security, which includes not only some means of providing for the later years of life, but also confidence in the continuity of work and opportunity for advancement.

These needs may vary in intensity from one individual to another, but the fact remains that they are present in some degree in most individuals. Many other human characteristics have a bearing on the ways in which these basic needs can be satisfied. For example, some people seem to thrive on responsibility, whether or not they handle it well, while others are more comfortable with minimal responsibility—more secure if they don't have to take chances. Some like repetitive tasks, while others become bored with such work and require more variety. Some are satisfied only if they can work out broad programs or do work requiring only gross manipulations. Still others prefer working out minute details or finishing materials to fine tolerances after the broad structure has been laid out. Not a few like to follow through an entire operation requiring both gross and meticulous work. Most people are content only when working closely with, or in the presence of, other individuals, while some prefer fairly long periods of relative isolation.

What happens when these basic human needs are not adequately satisfied or when an individual is placed in a job for which he is quite unsuited? Since man is remarkably resilient and adaptable, most people go ahead and do a creditable job although at a cost to themselves and their associates. But not a few find that they become indifferent to the job, preoccupied with other affairs, anxious and tense, or actively disgruntled and complaining. Some may become more accident-prone. Others may translate their difficulties into physical symptoms, presenting a remarkable variety of psychosomatic problems.

Such individuals appear with increasing frequency in the physician's office, in the complaint department, and on the sick-absence list. Since

these problems lead to increased sick absences and need for medical care, the occupational health department cannot fail to be interested, not only in the symptomatic treatment of patients with complaints, but also in the removal of those etiologic factors that may be present in the plant. The plant medical department has a stake in the reduction of sickness absenteeism to the bare minimum.

Job Placement

There are many different human physical and mental characteristics and abilities. Various jobs demand different levels of physical stamina and agility, different personality characteristics, and levels of ability and skill. The amazing thing is that, knowing this, we have been quite lackadaisical about trying to fit the man to the job. It has not been long since job matching was limited to "You look strong, you're hired." Now, of course, many places have analyzed their jobs so that the physical requirements of a given position are known and the applicant is checked to see if he can meet them. But it is indeed the exception to find a plant where the psychological requirements of the positions have been analyzed. Some little attention has been given to executive and supervisory positions, but very little to the bulk of jobs available. Actually, so far as psychological requirements are concerned, we are not even up to the point where we say, "You look strong, you're hired." Rather, we are still at the level where, if we were honest, we would say, "I think I know what I want, but I'm not sure, and I don't know much about you—you're hired."

Perhaps human characteristics are so common to the experience of us all that we either give them little formal thought or believe we understand them well enough to make consistently good judgments about them. Many individuals do a remarkably good job of assessing quickly the characteristics and needs of others, but most of us apparently do not, particularly when confronted with long lines of prospective employees and a minimum of time. The point is that most managements would not allow a judgment to be made after cursory observation of a piece of machinery—say a conveyor—that is to be purchased. Even though

any conveyor might serve the purpose, care is taken to examine all types—belt, chain, screw, and others—to determine which would be most efficient in a given operation. Yet, in the case of labor, which constitutes a major cost in most industries, we fail to analyze the psychological requirements of the job and assess the psychological characteristics of a man before putting him on the job. What is required is a little systematic thought about the basic needs of people and how these needs may be satisfied in the work situation.

Once having made the best possible judgment as to job placement, however, it is not enough to stop at that point. A certain amount of follow-up is necessary, not only to evaluate and improve selection and placement techniques, but also to detect any errors in placement at

the earliest possible moment so that a more suitable position may be found. All these steps require that the people in the health and personnel departments, as well as those in management, have an intimate knowledge of the plant and working conditions, know as many of the workers as possible, and have a genuine interest in people.

In short, the practice of good human relations can be boiled down to the simple phrase—it is important not only what you do, but how you do it. Those who are concerned with the how as well as the what of interpersonal relations usually practice good human relations.

Insect and Rodent Control Field Training Courses

Field training courses in insect and rodent control will be conducted by the Public Health Service Communicable Disease Center in Atlanta, Ga., July 14-25, and August 11-22, 1952. The first of the series was held in June. These 2-week programs are planned as refresher training for persons who have had experience in insect and rodent control or who are responsible for such activities. They are available to personnel of State and local health departments, the Public Health Service, and public health departments of foreign countries. Those who are preparing for public health assignments overseas will also find these programs of value. Persons from other organizations concerned with insect and rodent control will be accepted if facilities permit.

More comprehensive training courses are scheduled for September 22-October 3 (insect control) and October 6-24, 1952 (rodent control).

Application should be made by letter to: Officer in Charge, Communicable Disease Center, Public Health Service, 50 Seventh Street NE., Atlanta 5, Ga., Attention: Chief, Training Branch.

Public Health in Industrial Dentistry

A Symposium in Brief

The symposium briefed here was presented before the American Association of Industrial Dentists during the 1952 Industrial Health Conference in Cincinnati, Ohio. Dr. C. R. Fricke, dental director of the Duquesne Light and Power Company, Pittsburgh, Pa., was chairman of the discussion, which was held on April 24. Full texts of the papers are expected to be published in the Journal of Industrial Medicine and Surgery.

Dental Services in Industrial Plants

PHR Today, for an industrial population of 60 million, we know of only about 160 dentists, trained or experienced in industrial dentistry, who are providing scheduled service in industrial plants. An additional 1,000 are "on call," but they have had little or no training or experience in the recognition of oral manifestations of occupational diseases. Only one dentist is engaged on a full-time basis in industrial hygiene at the State level.

History

Industrial dental programs designed to treat accident or compensation cases were reported as early as 1914-15. The early history of these programs compared favorably with that of industrial medical services, but industrial dentistry did not keep pace with the expanding concept of industrial medicine. While the lat-

ter evolved from treatment of compensation cases to study of occupational diseases, industrial dentistry showed little inclination to study the effects of the environment on the oral structures. Emphasis in dental research has been placed chiefly on dental diseases common to children; consequently, industrial dental programs have remained more or less static.

Another obstacle has been the difficulty of evaluating preventive dental health services in industry. Reduced absenteeism, lower accident rates and workmen's compensation costs, and increased production have all been proposed as criteria, but they have had limited value. However, enough is known about the benefits of industrial dental programs to warrant their extension in industry.

Today's broadened concept of occupational health embraces the total health of the worker—nonoccupational as well as occupational influences. In keeping with this concept, industrial dental programs must be designed to prevent such nonoccupational diseases as caries and diseases affecting the dental tissues, as well as occupational diseases. With the exception of the use of fluorides, the preventive methods for control of nonoccupational diseases among adults parallel those for children—proper diet,

By Bruce D. Forsyth, D.D.S., dental officer for Federal Security Agency Region I at Boston. He served as an Assistant Surgeon General and the chief dental officer of the Public Health Service, 1948-52.

good oral hygiene practices, and early correction of dental disorders. Industrial dental programs seek to serve these ends through early diagnosis and encouragement of early treatment and proper oral hygiene practices.

In addition to observing caries and diseases of the periodontium, the dentist can detect early malignant processes in the oral cavity and on the face. Since early malignant lesions are relatively asymptomatic, the patient is probably not aware of their importance. Furthermore, the dentist has more opportunity for early detection than the physician, who usually sees people only when they report to him for specific treatment.

Dental Health Education

As soon as a preventive method has been developed and demonstrated to be effective, another important job confronts the dentist. He must promote widespread application of the method. This is an exceedingly complex job because it involves human attitudes, decisions, and actions. It involves public education, community participation in program planning, expenditures of private and public funds, train-

ing and availability of personnel to provide the service, administration and evaluation of the program, and many other activities. It requires a great deal of work on the part of many people in a community.

To conduct such a program successfully, cooperation is needed at all levels—between patient and dentist, among dental, medical, and citizen groups, and between industrial public health workers and local professional groups.

To assure such cooperation, a program of popular health instruction must be undertaken by the profession. Such a program should aim toward neutralizing the psychological factors of procrastination, indifference, and fear. It should bring knowledge of dental health to all groups and motivate them to apply that knowledge in their individual oral hygiene. A strengthening of our present educational activities would go far in stimulating public interest in dental health.

Dental programs have not yet begun to realize their potential to the extent that medical programs have. There is need for expansion of effort. The establishment of dental programs in industry can contribute materially to raising the oral health level of the whole country.

Community Approach to Dental Health

Many estimates have been made during the last several years of the needs for dental care in this country.

A review of these estimates presents a fairly comprehensive picture of the national dental health problem:

1. Children between 6 and 12 years old need 280,000,000 fillings to restore their mouths to a healthy condition, and adults need 425,000,000, a total of 705,000,000. In 1950, dentists placed 135,000,000 fillings, about 20 percent of the number required. It would thus take five times

the number of dentists we now have to catch up with the backlog of needed fillings.

2. Children would need 38,000,000 fillings every year to keep up with new cavities, and adults would need 100,000,000.

3. In 1950 dentists performed 48,000,000 extractions. No one knows or will even estimate the number needed.

4. In 1950 dentists made 1,500,000 crowns, bridges, and full and partial dentures. Again, no attempt has been made to estimate the number needed.

These figures represent a staggering amount of dental care. Yet to these figures must be added the need for an unknown quantity of dental and roentgenographic examinations, diagnoses, prophylaxes, topical fluoride appli-

By W. Philip Phair, D.D.S., assistant secretary, council on dental health, American Dental Association, Chicago, Ill.

cations, periodontal treatments, orthodontic care, oral surgical operations, root canal treatments, and other dental health services.

One of the brightest spots in this picture is the possibility of reducing a significant part of the problem in future years through the fluoridation of public water supplies.

Personnel Needs

The amount of dental work that can be done is limited by the number of persons qualified to perform dental operations. The bureau of economic research and statistics of the American Dental Association estimated in 1950 that there were about 74,000 active non-Federal dentists, of whom approximately 72,500 were doing chairside dentistry. During the last 10 years, the population of the Nation has increased about 15 percent while the number of dentists has increased about 11 percent. The number of civilians per practicing civilian dentist in the Nation is now about 2,100, the ratio varying in different sections of the country.

The dental education program in the United States is now geared toward reducing the number of persons per dentist. In the last 10 years, the total number of undergraduate dental students has increased by nearly 60 percent. New schools have recently been started, and presently established schools are expanding their facilities. In addition, the effects of the concentration of dentists in larger cities are less pronounced now than in former years because of modern methods of transportation.

Costs

In spite of the fact that only a small part of the public is seeking adequate dental care, Americans are spending approximately a billion dollars each year for dental care. In addition the Veterans Administration is paying \$40,000,000 a year to home town dentists for veterans' service-connected dental benefits, exclusive of dental care given at veterans' installations.

Add to these figures the toll represented in terms of general health, personal appearance, social adjustment, comfort, financial burden to individuals and taxpayers, and school and in-

dustrial absences, and you have something staggering enough to convince anyone that a problem exists.

What can be done about it? The answer lies in more efficient use of our present resources, rational development of new resources, research in the preventive field, increased application of preventive measures, and dental health education of the public.

Community Dental Health Program

The American Dental Association has long believed that needs can best be determined and met through individual and community effort. The approach to the problem of improved national dental health must be made largely through the development of community dental health programs.

Attributes that might be ascribed to a forward-going community dental health program, and most of them will also apply to industrial programs, include: (1) The program is attacking the community's dental health problem in a systematic manner. (2) It is successfully motivating people to assume personal responsibility for health, rather than unintentionally encouraging dependence on industry and government. (3) It is based on education, prevention, and early detection and correction of defects, rather than giving myopic and complete attention to the results of neglect. (4) It is an integral part of the over-all community or industrial health program. (5) It is buoyed by a continuous information program for its sponsors—whether they be community citizens or industrial management. (6) It is being evaluated scientifically on a periodic basis. (7) Probably most important, it has been planned with, and is receiving the constant consultation of, representatives of the people in the community and the dental profession.

Even though all groups do not have the same consciousness of need, the lay public, labor organizations, and the practicing dentists in the community all can and will contribute generously toward the development and maintenance of their dental program. Time and again it has been shown that when all are a part of the planning, agreement on methods of

accomplishing the objective of improved dental health is not as difficult as one would suppose.

During the past several years, common agreement has been reached on the purposes of dental health programs and on the basic principles by which they should be governed. The development of guiding policies is, of course, a continuing endeavor.

A tremendous potential exists within communities for the improvement of dental health. This potential can be realized through community action programs, developed by citizens groups, with the assistance of private dentists, public health and industrial dentists, and all health personnel on the local, State, and Federal levels.

Establishment of Industrial Programs

We have before us today the brightest picture in prevention we have had in the history of dentistry.

We are seeing the greatest interest yet shown by the layman in the care of his mouth. We stand to see a steady decline in the tooth decay rates of children treated with or consuming fluorine salts. We also see a tremendous growth in the corrective clinics established by health departments, school systems, and philanthropic organizations. But what is being done about the dental health of those over their elementary or even high school years? Are they to be left to drift?

The logical place to contact these people is at their places of employment, but the public health dentists and the private dentists cannot accomplish the job alone. It will take the best efforts of the rapidly growing group of industrial dentists.

Benefits of Program

The first efforts of the industrial hygiene dentists must be directed to assembling facts and statistics which will show management the need for and the benefits that can be expected from an industrial dental program. We must give them facts concerning hours lost, days lost, and material and production lost through dental disability. It must be brought to their

attention that absences are due not only to actual toothaches or local infection treated, but to diseases and conditions resulting from dental focal infections. Kolmer lists these: (1) the infectious arthritides; (2) rheumatoid or atrophic arthritis; (3) fibromyositis and bursitis; (4) neuritis; (5) subacute bacterial endocarditis; (6) iritis and other infections of the eyes; (7) pyelonephritis and other infections of the kidneys; (8) cholecystitis; (9) phlebitis and thrombophlebitis; (10) erythema nodosum; and (11) some cardiac arrhythmias; and also general debility, fatigue, anorexia, loss of weight, excessive drowsiness, headaches, hypochromic normocytic anemia, acquired hypotension, and reduced immunological resistance. These may be prevented or medical treatment aided by adequate dental examination and treatment.

Current Programs

Two industrial dental programs are now operating in Louisville. One of the programs is limited to visual examination, conference, and referral. The other, sponsored by the Louisville District Dental Society and started at the request of the company, is more comprehensive. It includes clinical examination, education and instruction in dental hygiene, referral, recall examination, and maintenance of records.

As a result of the latter company's request, the dental society formed an Industrial Dental Health Committee, which established the following requirements for the program:

By J. R. Robinson, D.D.S., director of dental health, Louisville and Jefferson County Board of Health, Louisville, Ky.

1. Examination must be performed by a dentist licensed by the State of Kentucky, and this appointment must be approved by the committee.

2. The participating company and committee must agree that the reference list consist only of members of the Louisville District Dental Society.

3. The company dentist shall refer each employee to his own dentist or shall issue a list, as above, from which he may make a choice.

4. In an emergency, the company dentist may give treatment.

5. Any employee who has regular dental care may present certification of this care in lieu of recalls and re-examinations by the company dentist.

The plan is in action and is offering an excellent service. Employees are seeking dental corrections, and it is anticipated that production will benefit from decreased physical slow-downs and days lost from work.

Responsibility of the Association

The objective of the American Association of Industrial Dentists is "to unite into one organization members of the dental profession and other persons or groups engaged or interested in industrial health, for the purposes of sponsoring the study and discussion of oral health as related to industrial health, productivity, and safety; standardizing methods for the conservation or improvement of oral health among persons in industries; initiating preventive industrial dental procedures; promoting a more general understanding of the purposes and results of dental health care of persons in industry; and encouraging the development of new industrial oral health programs and promoting mutual understanding with other categories of industrial hygiene personnel."

Convince Management

A first step toward these objectives must be to convince management that an industrial dental health service should be a part of the over-all health picture. Industry will generally not seek this service. They will not come to us and say, "We want a dentist for our health

services," until they have been made conscious of the need for such a service.

One approach to this problem is the promotion of demonstration programs in the plants, a method which has been used for several years in Pennsylvania. Equipment may be moved into a plant and a survey made of the dental health of the employees. The results should successfully demonstrate the need for a dental care program.

Further convincing evidence may be in the form of statistics. Insurance statistics show that employees with poor mouth conditions have a greater incidence of illness resulting in absence from work than those with good mouth conditions. Current surveys corroborate this statement, revealing an average of 4½ days per employee per year lost from work because of toothache or some dental ailment. An industrial manager should have only to consider such figures to see that a dental care program can save the plant money by reducing absenteeism.

Work With Labor Organizations

Cooperation with labor organizations has been suggested as an approach to the problem of establishing industrial dental health programs. Since we are confronted with the fact that in many instances these groups are setting up their own health services, would it not be advisable for this association to cooperate in planning the programs so that they will organize the type of program we know to be most practical?

By Edward R. Aston, D.D.S., secretary of the American Association of Industrial Dentists and industrial dental consultant, Pennsylvania State Department of Health, Harrisburg, Pa.

Educate Management and Employees

Another important responsibility is a dental health education program directed not only to employees, but also to management personnel. In fact, it is very important that management accept such a program before it is presented to the employees.

The education program may include the use of films, oral health classes, individual conferences, posters, pamphlets, and anatomical charts. Individual conferences are generally considered the best method.

Enlist Aid of Industrial Nurse

One of the best means of furthering dental education programs is to enlist the services of

the industrial nurse. The nurse has proper background for presenting to both the employee and management the problems confronting them in a health service and also the results that will be attained by solving these problems.

The nurse employed in a plant having an in-plant dental program may also be of service in assisting the dentist in periodic oral examinations and in giving treatment and emergency care. The nurse can also assume the responsibility of following up these employees to determine if correction has been obtained.

Furthermore, the industrial nurse has a wealth of opportunities to promote oral health through education since so many of her contacts with employees are under conditions which make them receptive to health information.

Community Dental Health Programs

Participation of various groups in community dental health programs was the theme of three papers presented at the dental health section of the twenty-first annual meeting of the Southern Branch of the American Public Health Association in Baltimore, Md., April 17, 1952. These papers appear here in abbreviated form. They are being published in full in the Bulletin of the American Association of Public Health Dentists.

State Health Departments

State health department personnel can and should play the roles of assister, encourager, promoter, stimulator, and even needler in local dental health programs. They should never, however, attempt to be dictators. The following principles may be helpful as guides in promoting community programs.

1. Programs should be planned with people, not for people.
2. Inviting people to help plan a program

will elicit greater response in terms of time and money than trying to "sell" them one already planned.

3. People are convinced by what they find out for themselves, not by what they are told.

By Carl L. Sebelius, D.D.S., M.P.H., director of dental hygiene service, Tennessee Department of Public Health, Nashville, Tenn.

4. Health programs need people who are not already overworked in other programs.

5. Every health service can be a springboard for health education.

Specific activities in which State health departments can be of assistance are described below.

Dental Health Education

Dental health education activities should be directed to four community groups: nonprofessional groups, school groups, public health workers, and dentists.

State health department personnel may be assigned to school groups to give talks, show motion pictures, consult with parents, and give clinical demonstrations. They may contact citizen groups by participating in local dental health conferences, discussing such subjects as water fluoridation, the role of carbohydrates in dental decay, and the need for more adequate dental service.

Postgraduate seminar programs conducted by the State health department can be an effective means of informing both dentists and public health workers of the latest developments in dental practice and procedures.

Preventive Dental Services

The development of topical fluoride programs and the promotion of controlled water fluoridation and carbohydrate control are the main activities in this field. One example of State health department aid is the topical fluoride treatment program recently carried out in one

large school. The local PTA paid for the services of the dental hygienists, and the State health department furnished supervision and equipment.

The promotion of controlled fluoridation should be primarily a local activity, but a State health department can serve as a source of information and can provide leadership. An example is the recent dental health workshop conducted by the State dental association, in which the State dental director, the assistant director of the division of sanitary engineering, and the commissioner of health presented factual information. The proceedings of this meeting have been published and can serve as a source of information for local groups.

Remedial Dental Activities

The State health department can assist in planning, organizing, and operating dental clinics. They can furnish equipment and supply lists, aid in obtaining personnel, and provide consultant services upon request. They may also loan portable equipment for use by local dentists in operating remedial programs in schools.

Evaluation

Statistical summaries of dental findings may be very useful in demonstrating the need for a well-organized dental program. State department personnel can be of service in making such summaries by providing forms to be used as an evaluation tool.

The Dental Hygienist

The history of dental hygienists dates back to the early 1880's, when Rhein suggested that dentists undertake to train women as "dental nurses to cooperate with dentists in cleaning and polishing the teeth, massaging the gums, and applying remedial agents. . . ." In 1887, C. M. Wright of Cincinnati, Ohio, pointed out that the work of the dental hygienist is an important factor in preventive medicine. It was not until

1916, however, that legislation was passed allowing dentists to employ dental hygienists. The way was thus paved for the introduction of the dental hygienist as a licensed practitioner of prophylactic dentistry.

By Louise G. Coira, R.D.H., supervising dental health educator, Pennsylvania State Department of Health, Harrisburg, Pa.

School Programs

One of the dental hygienist's most important roles is her part in the school health education program. Here she should be on a par with the public school teacher, teaching the children proper diet and how to have clean teeth. The hygienist, appearing in uniform, may arouse the children's interest in dental health by means of stories, rhymes, songs, plays, dramatizations, and tooth-brush drills.

If time does not permit the school dental hygienist to carry out such educational activities—English, art, music, spelling, mathematics, and, provide them with information. Dental health can be correlated with many other subjects: English, art, music, spelling, mathematics, and, in high school, chemistry and home economics.

Follow-up work is another important duty of a school dental hygienist. It is often not enough to send notices home to parents notifying them of dental corrections their child needs; it may also be necessary to make visits to the home. In addition, notices to parents complimenting them on the condition of their child's mouth when corrections have been made, or even if no corrections are needed, may be advisable.

The school dental hygienist should also include in her program the topical application of sodium fluoride. Not every pupil can be given these treatments in a school year, but one or perhaps two grades can be selected for the treatments. Since these treatments are recommended at the ages of seven and ten, the grades selected will probably be two and five. Some hygienists find that they can treat only one student at a time, but others find the "multiple

chair" technique can be applied effectively. That is, while the fluoride solution is drying for the necessary 3 minutes on one patient, treatment can be begun on a second and then on a third patient.

Community Activities

The dental hygienist should let it be known in the community that she is available to address groups such as the PTA and service clubs on dental health. Seeking their aid and cooperation in promoting local dental health programs is most important.

The dental hygienist should also maintain close contact with the dental profession. The cooperation of the dentists in the community is very necessary to the success of a dental health program.

Dental Hygienists in Pennsylvania

At present there are 143 dental hygienists employed in the public schools of Pennsylvania, in 132 districts. The dental health programs in these 132 districts include activities in education, prevention, and correction. However, there are many additional districts that have a corrective clinic and a sodium fluoride program but do not employ a dental hygienist.

On the staff of the Pennsylvania Department of Health are six dental hygienists, who are classified as dental health educators. The duties of four include contacting the public school dental hygienists at least once every year to advise and aid them. Of the other two, one is responsible for the department's sodium fluoride program, and the other handles the pre-school dental program.

The Dental Profession

The "Principles of Ethics" of the American Dental Association contains the following provision, which indicates the role the dental profession should play in State and local dental health programs:

"The dentist has the obligation of providing

freely of his skills, knowledge and experience to society in those fields in which his qualifica-

By Allen O. Gruebbel, D.D.S., M.P.H., secretary, Council on Dental Health, American Dental Association, Chicago, Ill.

tions entitle him to speak with professional competence. The dentist should be a leader in his community, especially in all efforts leading to the improvement of the dental health of the public."

Leadership by the dental profession is almost always an essential element in a successful community dental health program—leadership in studying and analyzing dental health problems and the resources needed to solve them; leadership in the establishment of facilities for the continuing education of dentists in matters concerned with the dental health of the public in general and dental health of children in particular; leadership in procuring the cooperation and active support of other professional and civic organizations; and leadership in the adoption of community plans which are best suited to the needs of the community.

As an illustration of what the dental profession is doing to supplement the work of State and local health departments, some of the activities of the State dental societies in California and Tennessee are outlined.

California

The California State Dental Association's dental health education committee, composed of about 140 members from all sections of the State, produces and distributes a large volume of educational material. During Children's Dental Health Week last year, for example, 263,000 dental health leaflets were distributed through the various component societies. Members of the committee are also instrumental in obtaining the assistance of local civic organizations in community dental health projects.

In promoting fluoridation of public water supplies, the California State Dental Association has found that one effective method of obtaining local approval is the organization of a citizen's committee. Such a committee, working with the dental society, can procure the support of interested community organizations.

Another activity which had unusual success

was the bitewing X-ray demonstration at the 1951 California State Fair. Bitewing X-ray inspections were given to 2,983 children, and the demonstration and accompanying exhibit were viewed by an estimated half million people. For the X-ray examination, a double film pack was used. One copy of the film was sent to the parents, who were urged to take it to a dentist for interpretation, and the second copy was used for statistical analysis.

The Southern California State Dental Association, also, has an extensive dental health education plan. One of its main purposes is to encourage dental practitioners to participate in educational activities in their own communities. The association has produced a series of transcriptions for use in radio and in schools and a film which is used not only in California but in most of the other States as well. About 150,000 pamphlets are distributed annually, and plans are under way to send 300,000 pamphlets to the members of the society for use in dental reception rooms and for other dental health education purposes.

Tennessee

Since 1949, the Tennessee State Dental Association has held annual dental health workshops, attended by nonprofessional as well as professional persons. Accomplishments of these workshops include (1) establishing of dental clinics in five communities, (2) reopening of the school for dental hygienists at the University of Tennessee College of Dentistry, (3) establishing of dental services in general hospitals, (4) opening of dental clinics in health centers, (5) purchase of mobile dental units by three counties, and (6) plans for a number of fluoridation projects.

The Tennessee association works closely with the State department of education for the development of more effective dental health instruction in schools and with the State department of health in many of its activities.

Pretesting: A Positive Approach to Evaluation

By ANDIE L. KNUTSON, Ph.D.

Persons responsible for health education programs have expressed need for some objective means of identifying the strong and the weak points in educational programs while changes are still possible.

Tests can be applied to health education activities while these activities are being planned and carried out. The positive approach outlined here makes use of objective data and methods. It includes two steps: (a) a critical review of the planning process and (b) an objective evaluation of requirements for achieving program goals.

This positive approach to evaluation (1) has been gaining recognition in recent years. It enables the evaluator to contribute to the improvement of a health education program before its structure is fully developed and large funds are expended.

The Planning Process

One way to assure that each activity be planned in the best possible way is to review systematically and thoroughly each step in planning. Such a review may be focused in terms of several broad questions.

Identification of Needs

Are the needs which the program is trying to satisfy identified by adequate exploratory fact finding?

A program directed toward improving health practices can have little possibility of success unless it is designed with an understanding of the persons for whom it is intended and

for their way of life. One should learn as much as possible about their experiences, interests, motivations, and patterns of behavior insofar as these relate to the problem at hand. What do they need? What do they want? How do they hope and plan to get it? What specific physical, sociological, or psychological characteristics do they have?

Studies of motivation have shown that individuals bring to any situation they face unique patterns of values and needs. As members of groups, individuals have common needs and experiences; they tend to develop common patterns of values. These serve them in sifting out of each new situation certain things to see and hear and to remember and act upon. People accept and use new information if it helps them to achieve their goals. They acquire new attitudes when these fit in with their past experiences and serve a useful purpose. Thus, motivations play a dynamic role in determining what people perceive as well as how they interpret what they perceive (2-4).

Questions such as these might be raised in reviewing a program: How does the problem tie in with those needs and values that most concern the group? In what way does the problem concern them individually? What can they personally do about the problem posed? How will members of this group use the specific in-

Dr. Knutson is chief of the experimental and evaluation services branch of the Division of Public Health Education, Public Health Service.

likened to a series of screens through which members of the potential audience must "filter" in order to be influenced by a program (5, 6). Trying out the screens with a sample of members of the audience gives a rough idea of how well the program may be expected to work when used with the total audience.

Part or all of a group may be lost through failure to satisfy any one of these conditions: For some reason, the medium or program material used may not be presented to them; if presented, it may fail to attract attention and sustain interest; if interesting, it may be too difficult for them to comprehend. As members of the audience are "screened out" through failure of the program at these specific points, the number who can be influenced is very much decreased. Once a member is lost, there is no way to win him back until the condition which led to his loss is satisfied.

If any of these conditions are not satisfied, those persons for whom the condition is not satisfied are lost to the program:

Exposure — How many persons will be reached physically?

Attention and Interest—How many persons physically reached will be reached psychologically?

Motivation—For how many reached will the program offer a means of satisfying a want or achieving a purpose?

Pattern of Behavior—For how many will the action that satisfies a want in this manner be in accord with the way people usually behave?

Comprehension—How many will understand the words, concepts, and illustrations used?

Understanding of Purpose—How many will really understand the point of the message?

Learning and Retention—How many will acquire and retain the information and attitudes essential for action?

Caution is necessary to assure that satisfaction of these conditions is not interpreted as evidence of effectiveness. Evidence that the specific goals of a program have been achieved is the only valid criterion of success (1).

Pretests of movies, slide films, exhibits, posters, pamphlets, and other media may be used to determine whether or not the conditions

necessary for effectiveness are being satisfied. Such pretests may be made while scripts and story boards are still in rough form—before plans for production are completed. On the basis of evidence obtained at this early stage, fundamental changes may be indicated. Necessary improvements can then be made quickly at a minimum cost to the program.

The pretest should determine whether each specific condition is satisfied for the members of the audience or population. It should also identify reasons for failure if the condition is not met for some members of the audience. Reasons for failure, when identified, will usually suggest means of improvement. Barriers to success may then be removed before the program is put into operation.

Any pretesting or pre-evaluation should be made on members of groups similar to those for whom the educational program is intended. Persons of different economic, social, and educational levels vary so widely in their experiences and in their goals in life that they cannot view social situations in the same manner. Professional persons reading a pamphlet developed for a group with limited education may react in a manner completely different from the non-professional worker for whom it is planned. Only by testing the pamphlet on a sample of lay persons for whom it is intended can we gain some assurance that it can communicate the message it carries.

The approach outlined here is not intended as a "blueprint" for meeting all problems of pretesting or evaluation. The needs of public health vary endlessly, both in kind and extent; educational programs developed to meet these needs vary accordingly. Major changes or variations may be required in the pretest approach and the techniques employed depending upon the particular program being evaluated. A wide range of variations exists both in the broad pretest pattern and in the techniques adapted or developed to test achievement of specific program steps.

Summary

Through a critical review of the planning process and through objective pretesting, an evaluator can contribute to the improvement

of health education programs as they are being developed and before large funds are expended.

The critical review should be made before pretesting is attempted for there is little value in pretesting a program that has not been adequately planned. Such a review should consider: (a) Are the needs which the program is trying to satisfy identified by adequate exploratory fact-finding? (b) Are the program objectives agreed upon, clearly formulated, and written down? (c) Is the method or approach used the one most likely to prove successful in achieving the program objectives? (d) Is the subject matter to be presented accurate, adequate, and impartial, and will it be accepted by those responsible for supporting and conducting the program?

The pretest should be planned in terms of certain specific conditions that need to be satisfied in order to achieve program goals. With these conditions met, the program will have a much better possibility of being successful in achieving changes in behavior. Pretests determine whether or not the conditions are being satisfied and yield data useful for improving a program. Although pretesting will not guarantee the success of a program, it will greatly increase the chances of success.

Many aspects of the problem of motivating people to improve their health habits are still unknown. Exploratory research in this area is badly needed. We also need to encourage and diligently pursue post-evaluation and

controlled studies of programs, both to determine program effectiveness and to identify unknown aspects of success or failure. Meanwhile, through pretesting, we can apply information now available.

ACKNOWLEDGMENT

This statement of concept was made possible by the following Institutes and Divisions of the Public Health Service which have provided the necessary financial support and practical problems for investigation: The National Cancer Institute, the National Heart Institute, the Division of Chronic Disease and Tuberculosis, and the Division of Venereal Disease. Helpful advice and assistance have been received from Dr. Mayhew Derryberry and members of the staff of the Division of Public Health Education, especially Dr. Benjamin Shimberg.

Dr. Hunt Appointed Assistant Surgeon General

Dr. G. Halsey Hunt has been appointed an Assistant Surgeon General of the Public Health Service. He will serve as an associate chief of the Bureau of Medical Services, which is under the direction of Dr. Jaek Masur.

Entering the Public Health Service as a commissioned officer in 1936, Dr. Hunt served on the surgical staffs of several of its hospitals, and in 1947 he joined the Bureau of Medical Services as assistant chief of the Division of Hospitals. He became chief of the division in 1949.

Dr. Hunt received his medical degree from Columbia University College of Physicians and Surgeons in 1928. He is a fellow of the American College of Surgeons and in 1951 was elected to the Board of Governors. He is also a member of the Surgery Study Section, National Institutes of Health, Public Health Service.

Hospital Beds in the United States, 1951

Under the provisions of the Hospital Survey and Construction Act, each State prepares and submits for approval to the Surgeon General of the Public Health Service a State plan for hospital and health facility construction. The first such State plan was approved in July 1947. Since that time there has been an increase of 141,958 acceptable hospital beds, 77,000 of which were acquired under the Hill-Burton program.

This review of the situation in 1951 presents figures on the number of hospital beds and estimated additional beds needed as shown by the State plans on January 1, in comparison with those for the preceding 3 years. Tables are given showing the number of existing beds and the net additional needed, by State, for general, mental, tuberculosis, and chronic disease hospitals, as well as the total for all categories. The number of existing, programed, and needed public health centers is also given.

(Ed. NOTE: A report on the current situation regarding hospital bed needs appeared in *Public Health Reports*, vol. 67, pp. 312-315, March 1952.)

Cronin, John W., and Odoroff, Maurice E.: Hospital Beds in the United States, 1951. (Public Health Service Publication No. 171) 1952. 16 pages; tables. 10 cents.

for the general public

Anemia

This nontechnical leaflet discusses what anemia is and gives a few facts about the blood, its composition, and

what it does within the body. Principal causes of anemia are given, such as improper diet, faulty absorption of food, loss of blood, injury to bone marrow, infection, and parasites. Symptoms and treatment are discussed briefly, with emphasis on a complete medical examination as the best preventive measure.

Anemia. Health Information Series, No. 55 (Public Health Service Publication No. 167). Reprinted 1952. 2-fold leaflet. 5 cents; \$1.25 per 100.

Pinworms

The nature of pinworms, their activities within the body, and the signs and symptoms experienced in infection are covered in this pamphlet. It stresses the fact that these parasites can infect adults as well as children, and may be a family affair. Means of controlling the spread of pinworms outside of the body are also discussed. No treatment is specified and readers are advised to consult their physicians.

Pinworms. Health Information Series, No. 51 (Public Health Service Publication No. 108). Reprinted 1951. 1-fold leaflet. 5 cents; \$1.25 per 100.

Care of the Feet

This leaflet is concerned with the various things that can go wrong with feet and why these conditions occur. Fallen arches, corns and callouses, bunions, foot odor, swelling of the feet, varicose veins, and athlete's foot are discussed. Advice is also given on proper care of the feet—wearing comfortable, correctly fitted shoes; bathing the feet; cutting the toenails.

Care of the Feet. Health Information Series No. 5 (Public Health Service Publication No. 109). Reprinted 1951. 1-fold leaflet. 5 cents; \$1.75 per 100.

Influenza

The epidemic nature of influenza, its symptoms, and the effect of the causative agent are pointed out in this leaflet. Preventive measures, such as avoiding crowds, keeping in as good health as possible, and isolating sick members of the family are advised. The use of vaccines is discussed, with the warning that no vaccine gives protection against all strains of influenza. The treatment advised is for the patient to go to bed and call a physician.

Influenza. Health Information Series No. 36 (Public Health Service Publication No. 163). Revised 1952. 1-fold leaflet. 5 cents; \$1.25 per 100.

Asthma

A general discussion of the physiology of the bronchial tubes and the nature of asthmatic attacks is followed by a description of the different causes of bronchial asthma. The wheezy, difficult breathing in asthma may also be associated with other diseases such as heart disease and obstructions in the bronchial tubes. Therefore, early diagnosis and prompt treatment by a physician are advised. The relation of climate to asthma is also discussed.

Asthma. Health Information Series No. 19 (Public Health Service Publication No. 155). Reprinted 1952. 6 pages. 5 cents; \$2.75 per 100.

Publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication (including its Public Health Service publication number). Single copies of most publications can be obtained without charge from the Public Inquiries Branch, Public Health Service, Washington 25, D. C.

The Public Health Service in 1952

The material presented in this review is excerpted from two recent publications of the Public Health Service. One is "The Public Health Service Today." It outlines the organizational structure of the Public Health Service and gives a broad picture of its operations. The other is the 1951 annual report, which presents in some detail the activities of the Service for the fiscal year 1951.

. . .

The Public Health Service Today. (Public Health Service Publication No. 165) 1952. 22 pages.

Annual Report of the Public Health Service, Federal Security Agency, 1951. 79 pages. 25 cents.

. . .

Good health for the people of the United States is a matter of vital concern. There are many agencies, voluntary organizations, and professional groups on local, State, and Federal levels all working toward the goal of longer and healthier American lives. The steady drive against diseases and environmental hazards that sicken, cripple, or kill is going forward on many fronts.

The United States Public Health Service is the principal agent of the Federal Government for protecting and improving the Nation's health. Its staff is constantly working to make more effective the multitude of efforts to conquer disease—conducting and stimulating research, aiding in the extension of health services and resources, and providing information and guidance to local and State agencies.

Job and Organization

The Public Health Service job can be summed up in three major aims:

- Conduct and support research and training in the medical and related sciences and in public health methods and administration.
- Provide a full range of medical and hospital services to persons authorized to receive care from the Service and aid in the development of the Nation's hospital and related facilities.
- Assist the States in the application of new knowledge to the prevention and control of disease, the maintenance of a healthful environment, and the development of community health services.

These three areas are reflected in the organization of the Service. Research is the principal responsibility of the National Institutes of Health; medical and hospital care is the responsibility of the Bureau of Medical Services; and aid to the States is the main job of the Bureau of State Services.

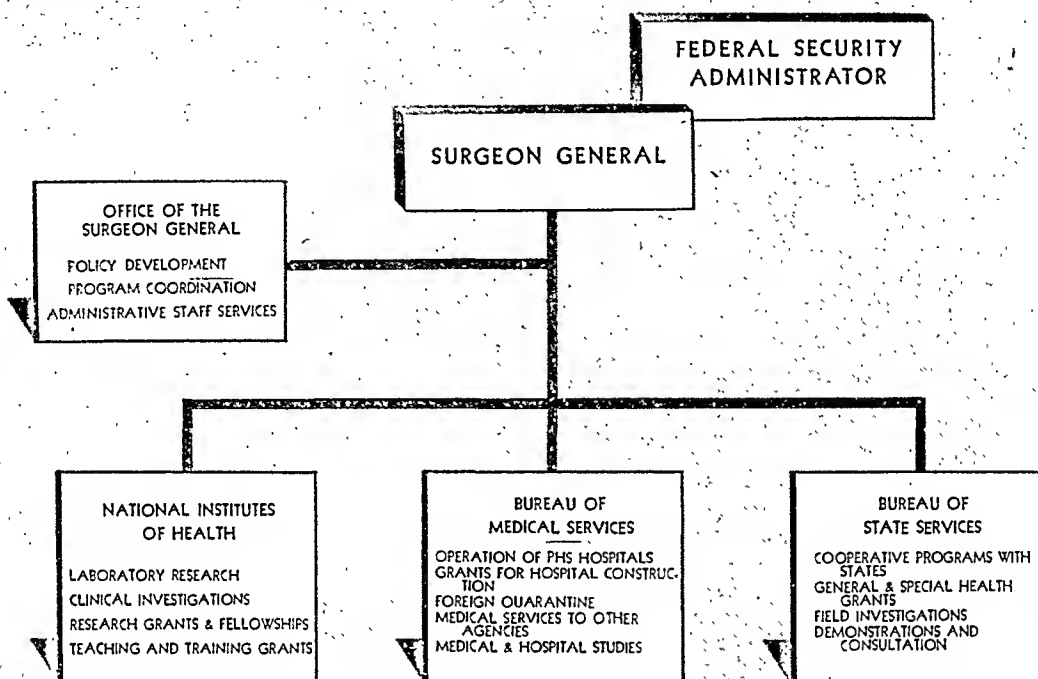

Administration of the Service is vested by law in the Surgeon General, aided by Assistant Surgeons General, each appointed from the Commissioned Corps. The Deputy Surgeon General is designated head of the Office of the Surgeon General—which is, in effect, a bureau of general administration.

Growth of Responsibilities

Since its beginning in 1798 as a medical care program for seamen of the American Merchant Marine, the Public Health Service has been called upon to assume many new responsibilities. Particularly in the past 15 years have advances in medical science and growing public awareness of the primary importance of health placed increased demands upon the Service.

As an example of how work of the Public Health Service has increased, the seven institutes in the National Institutes of Health have come into being since 1935, two of them since 1950. Although the Public Health Service has

THE BASIC STRUCTURE OF THE PUBLIC HEALTH SERVICE

been carrying on basic research for more than 50 years, the establishment of these institutes, in many instances consolidating previous activities, has resulted in a considerable expansion of the research program, particularly in the fields of chronic disease and mental illness.

The passage of the National Hospital Survey and Construction Act in 1946 increased the Public Health Service's responsibilities in the fields of medical, dental, and nursing resources and hospital facilities. In administering this act, the Service provides financial assistance and technical advice and leadership to State and local governments and to nonprofit organizations so that community needs for hospitals and health centers may be measured and plans developed to meet them.

The Public Health Service is engaged today in some 30 different programs, ranging from quarantine to chronic disease control and from the production of yellow fever vaccine to re-

search in atomic radiation. And not the least among these is the expanding participation of the Public Health Service in the progress in world health. In cooperation with the Technical Cooperation Administration of the Department of State and the Mutual Security Agency, the Service was assisting in the operation of health programs in 8 countries during 1951 and had plans either proposed or being drafted for programs in 18 others.

Service to Other Groups

As a focal point for health activities in the Federal Government, the Public Health Service program is intimately allied with many related governmental programs in education and welfare. As part of the Federal Security Agency, it works in close cooperation with other parts of the Agency, such as the Office of Vocational Rehabilitation, the Food and Drug Administration, the Office of Education, and es-

pecially the Children's Bureau of the Social Security Administration.

The Public Health Service also provides medical and technical services to many other agencies of the Federal Government whose general programs include medical and public health activities. For example, for the past 21 years it has supplied medical, psychiatric, dental, and nursing services to the institutions operated by the Bureau of Prisons. It assigns physicians to the United States Coast Guard to provide medical care for the crews aboard ships at sea, provides dental care, and inspects medical and dental facilities of the various sick bays and infirmaries. In addition, the Service assigns medical staff to certain bureaus within the Departments of Agriculture, Interior, Labor, and State.

In the interests of national defense, the Service, on request, provides technical staff and consultation to the Department of Defense, the

Selective Service System, the Atomic Energy Commission, the National Security Resources Board, the Office of Defense Mobilization and its constituent agencies, the National Research Council, the Federal Civil Defense Administration, and other Federal agencies.

The work of the Public Health Service, moreover, is linked closely with that of non-Federal agencies. It involves collaboration with State and local governments, medical schools, research foundations, professional associations, and voluntary agencies—in short, with the whole array of organizations concerned with the Nation's health. It is through the States, medical schools, scientific bodies, and similar groups that most of the benefits of Federal expenditures for health actually reach the public.

Personnel

To carry out its job, the Public Health Service today employs about 15,000 persons, who

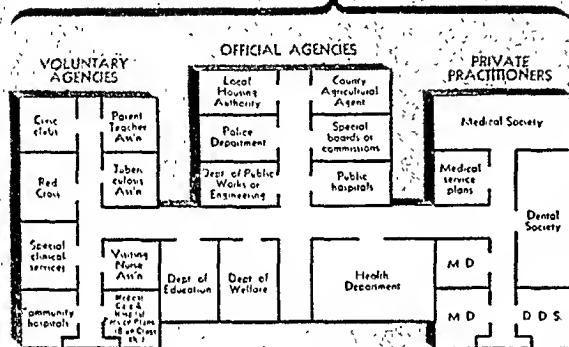

The FEDERAL RÔLE IN THE TOTAL PUBLIC HEALTH STRUCTURE

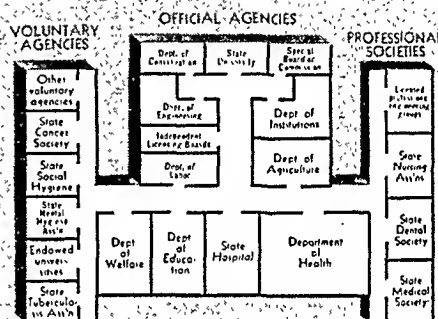

THE COMPLETE HEALTH STRUCTURE

NATIONAL AGENCIES

LOCAL AGENCIES

STATE AGENCIES

are engaged in more than 250 occupations and are located in more than 600 places. About 3,000 of this total are physicians, dentists, veterinarians, sanitary engineers, and nurses. Another 500 are scientists, and the remainder constitute allied and supporting personnel.

Most of these employees work in the field, either within the United States or in such remote places as Thailand, Liberia, and the Philippines. About 2,000 of the staff are headquarters employees in Washington, and another 2,000 are in the National Institutes of Health, Bethesda, Md.

1951 Appropriations

In carrying out its assignment during the fiscal year 1951, the Public Health Service administered \$332 million in appropriations and

authorizations. Nearly two-thirds of this total was allocated in grants to States and to institutions and individuals outside the Federal Government. Six percent was devoted to construction of needed facilities for the Service. The remainder covered its internal operations—its hospital and medical care programs, quarantine service, demonstrations, research activities, collection and reporting of vital statistics, technical aid to States, and administration.

Far more than half of the increase in appropriations to the Public Health Service during the past 15 years has been for grants to non-Federal agencies. The number of personnel on the payroll today is 1,500 below the peak of 1944 and has declined during each of the past 4 years even though Service responsibilities have substantially increased.

Manpower Shortages in Official Health Agencies

By WILLIAM P. SHEPARD, M.D.

Figure 1. Percentage of vacancies in budgeted positions for selected categories of professional and technical personnel in which 1,000 or more budgeted positions were reported in State and local health departments.

The acute shortage of professional and technical personnel is today the most serious problem in the field of public health. Trained workers, never available in numbers adequate to meet the needs of organized health agencies, are in steadily increasing demand from a number of sources. There are growing populations to be served by public health agencies, newly developed services to be provided, and new and urgent problems in connection with national

defense activities. Nor are the demands limited to personnel in public health. Physicians, nurses, dentists, and other professional workers are being called on to supply needed manpower in civilian activities related to defense. Thus, while the resources of trained health personnel are being depleted, demands for the services they are qualified to provide are constantly increasing.

The Health Resources Advisory Committee

of the Office of Defense Mobilization was appointed, as its name implies, to deal with the various aspects of health resources during a period of mobilization. Of serious concern to the committee is the problem of health manpower. The Public Health Service was called upon to study the staffing of State and local health departments and the utilization of personnel employed in these agencies. Reports on professional and technical personnel employed in official health agencies, as well as inventories of vacant positions and of staff members subject to military service, were requested. Information was submitted by State and local health departments in the continental United States, Alaska, the Hawaiian Islands, Puerto Rico, and the Virgin Islands. In this report, attention is limited to participating health agencies in the continental United States.

The high lights of the 1951 survey findings with respect to manpower needs and resources in the participating State and local health departments are presented in this report, which will be followed by a publication being prepared by the Public Health Service in which the information made available through the survey will be presented in detail.

Traditionally, basic minimum services provided by public health agencies have been built around the teamwork of physician, nurse, and sanitation worker. In the early days, their problems concerned the prevention and control of epidemics, the curbing of infectious diseases, and the provision of healthful physical environment. Present-day health departments, in addition to safeguarding the gains made in meeting earlier problems, face complex demands in many new fields. Chronic illness, the health problems of an aging population such as heart disease, cancer, and diabetes, social and economic factors in modern living, mental health, and new standards of acceptable environment are among the areas which must be taken into account in modern health department operation.

To gain a broad view of health department planning for both the new and the old concepts of service, information was sought concerning personnel in a number of occupational classes. Positions budgeted for laboratory personnel, public health investigators and health educa-

tors, medical and psychiatric social workers, among others, provided information on the direction in which programs are developing. For the professional and technical groups that make up the health department framework—physicians, nurses, engineers, and sanitarians—additional information as to age, sex, position, and status with respect to military service was requested. Because public health dentists and veterinarians are also subject to military call, they were included in the basic group.

Budgeted and Vacant Positions Reported

Reports of budgeted but vacant positions represent a gross understatement of total requirements, since, in general, the number of positions budgeted is not related to requirements. Available funds for personnel, rather than need, usually govern the total number of positions budgeted. Actually, budgeted positions as reported fail in many instances to indicate the total unfilled positions. Frequently, positions which remain vacant from one budgeting period to another are abolished when there is convincing evidence that candidates for appointment are not likely to be found. The study is informative, however, in that differences in the percentages of vacant budgeted positions for professional groups give some indication of where the greatest shortages exist. Such vacant positions reflect an immediate need recognized by health authorities as well as by appropriating bodies. Vacancies for physicians (20 percent of all positions budgeted for medical personnel), sanitary engineers (14 percent of that group), and dentists (21 percent) were greater than the proportion of positions vacant for sanitarians (6 percent) or veterinarians (10 percent). Although only 9 percent of the nursing positions were vacant, the total number of vacancies exceeded that of any other professional group. These six groups

Dr. Shepard, past president of the American Public Health Association, is a member of the Health Resources Advisory Committee, Office of Defense Mobilization. His report is based on a study conducted in 1951 by the Public Health Service for that committee.

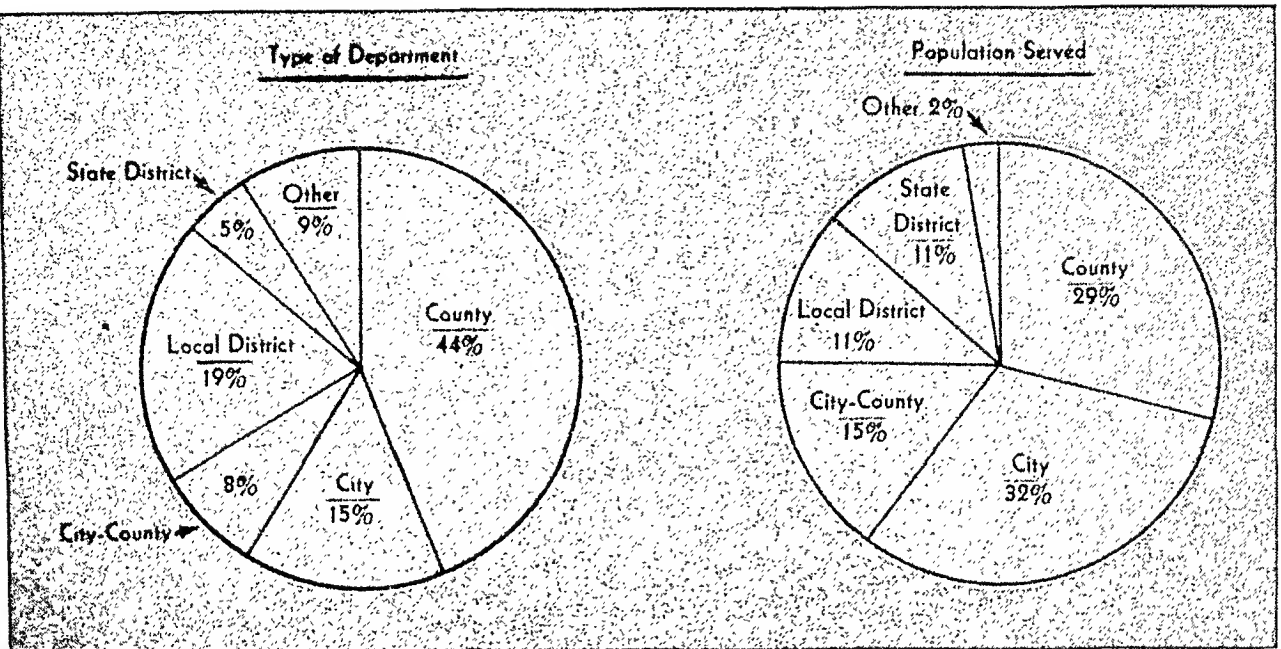

Figure 2. Percentage distribution of all local health agencies according to type of department and population served.

make up a considerable part of the staff for basic health department operations. Consequently, vacancies represent serious limitations on the effectiveness of health department programs and services. Some idea of the seriousness of the situation is revealed by figure 1, showing the percentage of vacant positions for certain categories of professional and technical personnel for which more than 1,000 budgeted positions were reported.

Budgeted and vacant positions in 20 categories of health department personnel, about which information was requested, are shown in table 1. The entire range of positions is shown here for purposes of comparison among the basic classes of personnel and those representing occupational fields less commonly found. In this report, attention is directed to selected categories.

Types of Departments Reporting

Reports on budgeted and vacant positions were submitted by 1,301 health agencies (table 2). State health departments accounted for one-fourth of all budgeted positions and reported 12 percent of their positions vacant. County health departments accounted for 20 percent of the total budgeted positions and

reported 9 percent vacant at the time of the survey. City health departments had the highest percentage of the total budgeted positions reported, and 9 percent were vacant.

Nearly half (44 percent) of the reporting local health agencies were single county health departments, providing services for almost one-third of the population covered in the survey. The percentage distribution by type of local health department and population served is shown in figure 2. Health departments classed as "Other" are, in general, one- or two-employee departments rendering limited services in rural areas.

Community Size

Of the 1,257 local health departments included in the study, only 2 percent were in the largest communities, those of 500,000 population and over (table 3). However, these departments accounted for 37 percent of the budgeted positions, and reported 9 percent vacant. Forty-three percent of the agencies were in communities of under 35,000 population. These health departments reported 9 percent of the budgeted positions, of which 12 percent were vacant.

The local health agencies participating in the

1951 survey which were located in communities of less than 35,000 population provided services for 12 percent of the population residing in health department jurisdictions. In communities with the largest population—500,000 and over—2 percent of the local health departments provided services for 28 percent of the covered population. Figure 3 shows—for communities of varying size—the extent of the relationship among the number of local health agencies, the population which they serve, and the number of budgeted positions. Communities range in size from those with less than 35,000 population to those of 500,000 and over. As may be seen, the percentage of budgeted positions bears a close relation to the proportion of population served in all except the largest communities.

More than one-fifth of the physicians, nurses, and sanitation personnel (sanitarians and engineers) of all county health departments were employed by the health departments in the smallest communities. On the other hand, small city health departments (those serving under

35,000 population) reported only 3 percent of the public health workers in these classes employed by all city health agencies. This suggests serious understaffing for providing even the minimum of essential public health services, and clearly indicates the need for consolidation of small municipal health departments into a broader base for more effective administration.

Military Reserve and Public Law 779

For the six selected professional and technical categories of health department workers previously mentioned, health agencies participating in the study provided information as to age, sex, position, and liability for military service. Physicians, dentists, and veterinarians were the first professional groups to be registered for military draft under the provisions of Public Law 779.

This law, a 1950 amendment to the Selective Service Act of 1948, required the registration of men under 50 years of age in medical, dental,

and allied specialist categories who were not members of a reserve component of the armed forces. The first registration, in October 1950, included physicians, dentists, and veterinarians in two groups: (1) Those who had participated in specialized training programs of the Army or Navy, or who had been deferred during World War II to pursue their education in one of the special categories and had less than 90

days of active duty in the armed forces or in the Public Health Service after completing their education; (2) the same groups, under the same conditions, who had 90 days or more but less than 21 months of such active duty. These two groups were assigned the first and second priorities for induction into the armed services.

Later registration included persons in the same specialist categories who were not included

250,000-499,999-----	32	2	2, 380	10	214	10	9
500,000 and over-----	25	2	8, 555	37	752	36	9

in the first registration and who had had no active duty after September 16, 1940. The final group included all men in the specified categories, not liable under the earlier registrations, classified according to the number of full months of active service, to be called upon when all those available under higher priorities had been inducted. These two groups were designated as priorities 3 and 4.

Among the 1,283 male physicians, dentists, and veterinarians under 50 years of age who were included in the survey, 33 percent were reported as having status in the military reserves or in priorities 1 and 2 under Public Law 779 (table 4). This group is most immediately subject to call for military duty as they are needed, either during the period of mobilization or in the event of national emergency.

In six selected categories of professional and technical health department personnel of all

ages and both sexes, 10 percent were reported as having status in some component of the military reserves (table 5). It should be noted that more than one-third of all engineers reported are in this group.

Call to military service therefore threatens to deplete further the available public health workers. Of serious import is the fact that about one-third of all health officers and chiefs of service, those responsible for the direction and administration of programs and activities, are in either the military reserves or registered under Public Law 779.

Resources and Needs

Physicians

Among the selected categories of professional and technical public health personnel, the shortage of physicians is perhaps of greatest importance in terms of impact upon health department operation. This critical situation is highlighted by the fact that 991 health departments reported 2,219 budgeted positions for physicians, of which 443 were vacant at the time of the survey. These were vacancies in established positions, and in the agencies where they occurred the full duties and responsibilities involved were not being carried on. The highest percentage of vacancies was in health departments in the smallest communities, where almost one-third of the budgeted positions were vacant. When budgeted positions for physicians average approximately one to each agency,

Table 4. Military status of male physicians, dentists, and veterinarians reported by State and local health departments (through age 50 only)

Profession	Total	Military reserves or priorities 1 and 2	Percent
Total-----	1, 283	429	33
Physicians-----	942	298	32
Dentists-----	189	73	39
Veterinarians-----	152	58	38

it is obvious that a health department with a vacant position is usually a health department without medical administrative leadership.

In State health departments, vacant positions do not necessarily imply lack of leadership in medical administration but are more likely to mean less effective operation of established services, delay in initiating new services, and an overloading of the physicians in the department. In many State health departments there is considerable "doubling up" of the direction of programs and services, so that a single physician will be responsible for the direction of one program and be designated as acting director of one or several others. This procedure is resorted to because essential services must have continued direction, and vacant positions simply cannot be filled. The percentage distribution of budgeted positions for physicians according to the size of the community, the type of department, and geographic area is shown in figure 4. The light areas represent the percentage of vacant positions reported. The geographic areas are:

Region	States
Northeastern-----	Connecticut, Delaware, District of Columbia, Maine, Maryland, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, Vermont.
Southern-----	Alabama, Arkansas, Florida, Georgia, Kentucky, Louisiana, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, Virginia, West Virginia.
Central-----	Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota, Wisconsin.
Western-----	Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, Wyoming.

Two-thirds of the physicians reported were health officers or chiefs of service. Thirty-two percent of this group were in either the military reserves or registered in priorities 1 and 2 under the amended Selective Service Act. Thus, in the event of general call-up to the armed forces, health department operation and program direction and supervision would be jeopardized because of lack of leadership. Shortage of physicians in public health is not a new

Table 5. Professional and technical personnel in six selected categories reported by State and local health departments as having status in the military reserves

Category	Total	Military reserves	Per cent
Total-----	21, 571	2, 186	10
Physicians-----	2, 074	371	18
Nurses-----	12, 044	691	6
Engineers-----	1, 071	411	38
Sanitarians-----	5, 758	590	10
Dentists-----	305	68	22
Veterinarians-----	319	55	17

development, and it is unlikely that replacements would be generally available, even from staff workers in health departments. Most other physicians reported were at the staff level, with only 5 percent listed as consultants and supervisors.

Unquestionably, this study indicates that the shortage of physicians for service in health departments is critical. One-fifth of the budgeted positions for physicians were vacant at the time of the survey, and a large proportion of those presently employed are subject to recall or induction into the armed services. The problems of health department operation must therefore be considered in the knowledge that physicians are and will continue to be unavailable in anything like the numbers needed even to maintain present services. There must be a continuing critical analysis of the activities of medical personnel, looking toward the most effective utilization of those now serving in official health agencies. Consideration should be given to ways of supplementing their services by a greater use of part-time clinicians and of nonmedical assistance in those activities which can be delegated to such personnel.

Nurses

In an article on "Nurse Power in Mobilization," Ruth P. Kuehn (1) stated: "A critical deficit in nurse power is already upon us, and this deficit is steadily increasing." The deficit in health department nurses was indicated in the 1951 survey, which showed that 1,062 budgeted positions for graduate nurses were vacant. As with physicians, these vacancies

Figure 4. Percentage distribution of budgeted positions for physicians reported by State and local health departments according to type of department served, and for local health agencies according to community size and geographic region.

in budgeted positions represent pressing needs for nurses in established positions for which funds were available and which were unfilled because of the shortage of "nurse power."

It is recognized that in many communities visiting nurses and school nurses work closely with health departments, and in some instances carry a considerable share of the nursing load. However, this study deals only with health department nurses.

Nurses in health departments serve all programs and provide the hard core of services in the field of personal health, the essential routine tasks of home and school visits, of health edu-

cation and its application to personal living, among many other duties. In this important basic service, 1 budgeted position in 10 was vacant. Needs for additional nurses reveal the greatest deficiency in total numbers in health department personnel. The number of vacant budgeted positions represents about one-tenth of the total number of nurses who would be needed to bring existing health units up to minimum standards—approximately 10,000 rather than 1,062 as reported. For nurses, as for physicians, there must be a continuing critical analysis of activities to assure the most effective utilization of those now employed in offi-

Figure 5. Percentage distribution of budgeted positions for nurses reported by State and local health departments according to type of department served, and for local health agencies according to community size and geographic region.

cial health agencies and to explore and evaluate the potentialities of supplementary workers without the technical skills and training of the qualified nurse.

Shortages of nurses were reported in all types of departments and in communities of every size in every State. The percentages of budgeted positions for nurses according to size of the community, type of department, and geographic region are shown in figure 5. The light areas represent the percentage of vacancies in each category.

Health departments provided information concerning 12,044 nurses. The median age, in

an occupation for which preparation is completed at a relatively early age, was 41 years—somewhat older than might have been expected. Since only 6 percent of the total number of nurses reported status in the military reserves, it would seem that depletion of the nurse supply in health departments is not particularly due to their being called to active military service. Many nurses, however, are joining the armed forces. Most of the vacancies reported because the incumbents had entered active duty were in nursing positions.

Only 369 nurses were reported as chiefs of service or health officers. The greatest number

of nurses were staff workers, with about 8 percent reported as supervisors and consultants. The shortage of nurses, therefore, bears directly on the provision of day-to-day actual services to individuals, rather than on program direction or leadership, as in some of the other occupations. The nursing profession, which women enter fairly young and leave because of marriage, family responsibilities, and the like, does not have an adequate reserve supply from which to provide replacements. To quote again from Mrs. Kuehn's article, "The present supply of nurses must meet all needs until more graduate nurses can be produced." At present, the production of nurses is insufficient to meet the demands.

Sanitarians

The third member of the team in providing minimum essential public health services is the sanitarian. Like the nurses, sanitarians carry on the routine tasks essential in safeguarding the public health. Such important duties as the inspection of facilities for storing and serving food, maintenance of safe water supplies, and provision of physical environment favorable to personal health are assigned to the sanitarian.

Activities concerned with environmental sanitation are essential to the health and welfare of all communities. The concentrated populations in urban communities, and more recently in and near military and industrial centers concerned with defense activities, make sanitation services in these areas of vital importance. Although the rate of vacant positions for sanitarians was relatively low, the urgency of maintaining the full range of their services gives these vacancies added importance. As with physicians and nurses, the budgeted positions for sanitarians by no means reflect total need. If all presently organized health departments were to meet minimum staff requirements, it is estimated that more than 1,600 additional sanitarians would be needed.

County health departments were most numerous among the agencies reporting budgeted positions for sanitarians. However, the greatest number of positions were in city health departments, 156 of which reported 2,312 budgeted positions, with 98 vacant. The distribu-

tion of budgeted positions by community size, by type of department, and by geographic area are shown in figure 6. Light areas indicate the percentage of vacant positions in each category.

State and local health departments listed 5,758 sanitarians employed at the time the study was made, with only 62 women sanitarians reported. The employment of women in greater numbers in this field might be suggested. It seems reasonable to believe that they would be successful, especially in the inspection and supervision of the servicing of food.

Only 10 percent of the sanitarians reported status in the military reserves. Although they are a relatively young group and they may be taken into the military services, their replacement would be less difficult because many sanitarian jobs can be filled by personnel with less professional preparation than can other types of public health positions. Most of the sanitarians were listed as staff workers, and many of them were listed as the only worker in their field in the reporting agency.

Engineers

In the larger local health organizations and in State health departments, sanitary engineers are employed not only for the handling of and consulting on the more complex aspects of environmental sanitation, but also for the direction of environmental health programs. Their specialized training and skills are required for the supervision of sources of water supply and for the planning, construction, and operation of water treatment systems and sewage treatment and disposal systems; for dealing with problems of water and air pollution, and of industrial health hazards. Because of their specialized training and experience, the services of sanitary engineers are in immediate demand whenever disaster strikes. In the event of a military attack on the United States, and in areas devastated by floods, fires, or tornadoes, they are needed to provide front-line defense against the health hazards that follow serious disruption of environmental sanitation facilities and services.

The demand for sanitary engineers is not limited to official health agencies. Their services are sought by organizations which plan and develop industrial installations involving safe

Figure 6. Percentage distribution of budgeted positions for sanitarians reported by State and local health departments according to type of department served, and for local health agencies according to community size and geographic region.

and healthful environment, by planning commissions and boards concerned with watersheds, by interstate public carriers, by water pollution control agencies, consulting firms, public works agencies, industry, and academic institutions. The needs of the armed services may well place an additional drain on the limited numbers available in the field of sanitary engineering.

Engineers were the youngest among the six groups for whom age information was supplied. In view of the fact that 38 percent were reported as having status in the military reserves, and are largely of an age to be called to service in case of need, health agencies face a poten-

tially acute problem of depletion of their already limited resources of engineering staff. The greatest number of engineers reported military reserve status in the Army; only a small number were reported in Public Health Service Reserve components. Engineers have not been registered under Public Law 779 up to the present time.

Among all occupational groups in health departments included in the survey, engineers ranked sixth in the number of budgeted positions reported, and seventh in percent of budgeted positions vacant. However, among the six selected categories of public health personnel—

Figure 7. Percentage distribution of budgeted positions for engineers reported by State and local health departments according to type of department served, and for local health agencies according to community size and geographic region.

physicians, nurses, engineers, sanitarians, dentists, and veterinarians—engineers had the third highest percentage of vacancies in budgeted positions. In view of the specialized nature of their work, it was not surprising to find most of them employed in State health departments. Budgeted positions distributed by size of community, type of department, and geographic area are shown in figure 7. The light areas indicate the percentage of vacancies in each category.

Dentists and Veterinarians

Dentists and veterinarians are employed in

limited numbers in State and local health departments, although there has been a growing recognition of their place in public health.

Public health agencies have been developing programs of dental public health for a number of years. However, in the 1951 survey, budgeted positions were reported by only 136 health agencies, 98 of which were local and 38, State health departments. As was noted earlier, the vacancy rate in budgeted positions for dentists was among the highest reported. More than half of all budgeted positions were in the largest communities. Vacancy rates were relatively high in communities of all sizes, and in all types

Figure 8. Percentage distribution of budgeted positions for dentists reported by State and local health departments according to type of department served, and for local health agencies according to community size and geographic region.

of departments, as indicated by the light areas in figure 8.

Until comparatively recent years, the duties of veterinarians in public health agencies were closely related to those of inspectors in the field of environmental sanitation. However, with emphasis being placed on the control in animals of diseases transmissible to man, a separate professional category has gained recognition in the public health field. It is probable that in the present survey many of the veterinarians whose duties were still largely concerned with the inspection of meat, poultry, meat products, and related activities were reported as sanitarians.

This would account in part for the fact that only 139 agencies (126 local and 13 State health departments) reported budgeted positions for veterinarians. The veterinarians were located mostly in the largest communities and in city health departments, with few veterinarians reported in State health departments. The distribution of budgeted positions, with the light areas indicating vacancies, is shown in figure 9.

Because of the small numbers of dentists and veterinarians reported by State and local health departments, the age distribution, status in the military reserves, and priorities established under Public Law 779 are only indicative of the

problems to be faced in filling vacant positions and in enlarging or extending present services in these fields. Almost half of the dentists and one-third of the veterinarians were in either the military reserves or registered in one of the four priorities under the amended Selective Service Act.

With the present shortages of both dentists and veterinarians, even the complete staffing of programs now in operation presents serious problems. The possibility of extension or expansion of work in either dental public health or the field of veterinary medicine seems extremely unlikely, except perhaps through a more general use of supplementary personnel. In public health dentistry, dental hygienists are being used in a relatively small number of agencies. They too, however, had a fairly high rate of vacancies at the time of the survey.

The work of the trained public health veterinarians may be extended to a certain extent by sanitarians. However, wider incorporation of such programs within basic public health services will be seriously restricted until the supply of trained personnel is greatly increased—a day which at this time seems far in the future.

Ratios as a Measure of Needs

Although the use of ratios in determining needs for personnel has many limitations, they do provide some measure of need when care is taken in their interpretation. Recommended ratios of public health personnel to population, as determined by authorities in the field, specify 1 physician as health officer in each organized health department plus 1 physician for each additional 50,000 population living within the health department's jurisdiction. For nurses, the recommended ratio is 1 to 5,000 persons if bedside nursing care is not included, 1 to 2,000 when bedside care is provided; for sanitarians, 1 for 15,000 population.

These minimum staffing requirements, developed over a period of years by representatives of official and nonofficial health agencies working together, represent a consensus of professional judgment. The great disadvantage in using ratios to determine needs for public health personnel is that problems vary greatly in dif-

ferent communities, in different parts of the country, and with differing emphasis given to particular programs and areas of interest. However, there must be some common basis from which to measure personnel requirements, and ratios carefully used provide such a base. Under any circumstances, there could be no firm statement that health departments of a certain kind in a certain community would need a given number of persons to carry out a "public health" program. The best estimates are merely that—a rough measurement of needs—and ratios provide the means to make such general measurements.

Ratios of Reported Personnel to Population

In all health departments included in the 1951 survey, regardless of the size of community served, the personnel available in relation to the number of persons within the jurisdiction was far from the recommended ratios. The ratio of nurses and sanitarians to population was in general fairly constant. It showed 1 nurse for 10,000 to 12,000 persons. Sanitarians averaged 1 to about 25,000, except in health departments in communities from 250,000 to 500,000 population, where the number of persons per sanitarian was about doubled. The ratio of persons to health department physicians increased as the size of the community served by the health department increased, ranging from 1 physician for 45,000 persons in the smallest communities to 1 for almost 120,000 in communities of 250,000 to 500,000. In the largest communities (those of 500,000 and over), the average was 1 physician for about 75,000 people. In these larger communities, however, the problem may be less serious since it is somewhat easier to extend the services of the public health physician by a greater utilization of part-time clinicians.

Summary

The health manpower survey has not only confirmed the generally known facts concerning shortages of trained public health workers, but has also identified specific critical situations arising from these shortages. In health departments in 1951, 10 percent of all budgeted

Figure 9. Percentage distribution of budgeted positions for veterinarians reported by State and local health departments according to type of department served, and for local health agencies according to community size and geographic region.

positions for professional and technical personnel were vacant. Vacancies were especially numerous in positions for physicians, nurses, and engineers—professions essential to public health program operation.

In budgeted positions for physicians, 443 were vacant. There were 1,062 positions for nurses and 303 for sanitarians reported vacant in the 1951 survey. Vacancies in budgeted positions represent only a fraction of total need for public health personnel. To bring existing local health departments up to minimum recommended standards, it is estimated that there would be need for nearly 1,000 physicians,

more than 10,000 nurses, and about 1,600 sanitation personnel, including both sanitarians and sanitary engineers. To extend basic minimum services in organized health units to the entire country would require in the neighborhood of 1,600 physicians, 13,700 nurses, and 4,000 sanitation personnel.

Most significant to the operation of presently organized health departments, and to the expansion of public health agencies to areas not now covered, is the shortage of physicians. Shortages of engineers are almost equally serious, in view of the nature of their work and the demands for their special kinds of services

in a period of national emergency. Although the shortage of nurses is very large, it is believed that the reservoir of trained nursing personnel—such as nurses who have withdrawn from active participation in health programs for personal reasons—could be drawn on to provide nursing services in the event of a military or natural disaster. They might also be called on to staff new agencies, to provide new services, and to participate in nursing activities at least on a part-time basis if the need arises.

The considerable numbers of public health personnel reported as having status in some component of the military reserves or as liable to call under the amended Selective Service Act, pose additional problems. These public health workers may well be lost to official health agencies because of the needs of the armed forces. There is scant hope that a greatly increased supply of public health workers will be available while the mobilization for defense, with its extensive manpower requirements, continues.

During this period, a demand of formidable

proportions for trained public health personnel will build up, which, under the most favorable conditions, will take years to meet. In view of the findings concerning present health organizations and methods of utilizing available personnel, it is essential to make a purposeful examination of present operations and by prompt and vigorous action to correct wasteful and inefficient practices wherever they exist.

ACKNOWLEDGMENT

The author acknowledges the assistance of the Division of State Grants of the Public Health Service in planning and conducting the survey of health manpower in State and local health departments. He is indebted to Dr. Marion Ferguson for planning the collection and analysis of the data and for the preliminary tabulations and reports, and to Bess Cheney for assistance in preparing the final tabulations, analyses, and the text of the report.

Training Course in Environmental Health

Fourteen technical training courses will be offered by the Public Health Service Environmental Health Center, Cincinnati, Ohio, during fiscal 1952. The first, a course in basic radiological health training, is scheduled for October 6-17.

In addition to seven courses in radiological health, courses will be conducted in the fields of water pollution abatement, sewage, industrial waste and water treatment, milk and food sanitation, and atmospheric pollution control. The courses are designed for professional personnel from State and local health departments, water pollution control agencies, the Public Health Service, and other governmental units. Industrial representatives who are cooperating with these agencies in environmental sanitation and radiological health programs are also eligible to attend.

A bulletin giving the complete schedule, descriptions of the courses, and application information may be obtained upon request from the Officer in Charge, Environmental Health Center, Public Health Service, Cincinnati, Ohio, or from Federal Security Agency Regional Offices.

STATISTICS

Public Health Reports publishes in this and later issues a group of papers presented before the Second Conference on Public Health Statistics held June 16-20, 1952, at the School of Public Health of the University of Michigan.

This second conference—the first was held in 1948—was designed for health officers, program directors, and public health statisticians. These and other professional groups and disciplines were represented in discussions which ranged over a wide array of topics . . . the use of statistics in State and local programs, in general and specialized programs, in administration, in evaluation. Special attention was given to current developments and potentialities in survey and sampling methods.

Vistas in Public Health Statistics

By CLARENCE J. VELZ, M.S.P.H.

By whatever means one projects into the future, there appear on the horizon broadening functions and challenging fields of labor for the public health statistician. With this increase in scope one sees the public health statistician occupying positions of greater and greater responsibility on the public health team. One also sees closer day-to-day relation between the administrator and the statistician in planning, executing, and evaluating public health programs.

The public health statistician, however, should not be expected to bring suddenly into

bold relief straight and unerring paths to success in all public health effort. The statistical method is an aid, but it is not a substitute for thinking and creative imagination. However, no administrator is so rash as to venture forward without the aid of this powerful tool. Thus one sees the public health team venturing forward, led by a courageous and imaginative administrator with the public health statistician at his side, sounding, probing, testing, sifting, evaluating.

That this opportunity is not a mirage but a reality is fortified by today's changing concept of public health, the pressure of expanding functions and new problems, and the increased power of new statistical tools. The public health task is conceived today to be the provision of not only an environment in which man can survive, but also one in which he will thrive. In the early years the task was conceived primarily as the conquest of the ravages of communicable disease. While the potentialities of

Mr. Velz is professor of public health statistics and chairman of the department of public health statistics, School of Public Health, University of Michigan, Ann Arbor. This paper was presented June 16, at the Second Conference on Public Health Statistics at the University of Michigan.

epidemic disease still exist, today in the public mind the threat to survival is remote, and emphasis is shifting from "survive" to "thrive" with demand for positive health.

This changing concept greatly broadens the field of action. It also complicates and makes more difficult definition of problems and measurement of results. With the shifting of emphasis from survive to thrive, the basis for action is more vague and difficult to define and the measure of effectiveness more intricately interwoven with other public services.

There is no one short sure road to positive public health. Some roads may prove to be blind alleys; some may prove to be exceedingly expensive excursions; others may not appeal to the American way of life. Nor is the public health profession the only one in the field competing for public support on the road to that goal of "a better life." This much is certain: the public health team must justify the selection of the roads it takes and demonstrate that it is consistently moving toward the goal and not just traveling blind.

New Measurements

To chart these paths and mark progress is a challenge to the whole public health profession and particularly to the public health statistician in development of new measuring devices. At one time, death rate was an all-inclusive yardstick by which a problem could be defined and progress marked. From this simple, direct device the future leads to an ever-increasing chain of complexity: recording of births and deaths; partial reporting of communicable disease; shift from acute epidemic to chronic disease; shift from mortality summaries to morbidity surveys; periodic and then continuous sickness surveys; and finally, measurements in terms of positive physical and mental well-being and an environment conducive to thriving.

Although sights may be set on thriving and goals of positive health, it is not implied that competitive and self-inflicted hazards of life are all removed. Life probably always will remain a battle to survive. Hence, with the changing concepts of public health, new functions do not replace old responsibilities. There

remains, always, the important work of improving accuracy and completeness of recording, of extending, not diminishing, communicable disease reporting, and of expanding generally the usefulness of mortality and morbidity data.

In the early days the administrator had very little need for services of the public health statistician beyond record keeping. Today the situation is quite different. In light of changing concepts of public health, it is inevitable that the public health administrator and the whole public health team are destined to lean more and more heavily on the public health statistician for aid in charting paths, appraising programs, and measuring progress.

In addition to the long-range influences associated with changing concepts of public health, new problems and expanding functions are already appearing. They are demanding immediate extension of the services of the public health statistician in environmental health, industrial health, medical care programs, community planning, and in over-all departmental management.

Environmental Health

One sees in the future a vast expansion of work for the public health statistician in the field of environmental health and a much closer working relation between the public health statistician and the public health engineer. We have been inclined either to view man as an isolated case independent of his environment or to deal with the environment as independent of the individual. Actually, man is inseparable from his environment. The trend is toward integration of the total environmental situation in which modern man lives and through this complex and varied context to identify and provide the beneficial and eliminate or control the detrimental. In this task the statistician can be of great assistance to the engineer.

As we proceed from the concept of survive to that of thrive, much that is undertaken in the name of environmental health will not be measurable in terms of death rate, or even sickness rate. Sensitive measures of environment itself and its relation to well-being must ultimately evolve.

Consider the water contact. The battle against stream pollution has been held back for years because of the old negative point of view written into public health law requiring demonstration of injury to health before corrective action could be enforced. Today State after State is in process of changing laws from a negative to a broad positive concept of multiple uses of streams, a concept which includes such intangibles as recreational value. No longer is it necessary to show that someone dies or becomes ill as a justification for pollution prevention and control of the water contact. Here, again, statistical methods must be applied to stream analysis and the evaluation of the mass of operational control data required of municipal and industrial water supplies, waste-treatment effluents, bathing beaches, and fishing and recreational areas.

Air Contact

Similarly, in the air contact, the concept is broadening to include not only the indoor industrial hazard but also outdoor atmosphere, including climatological aspects, fungi and pollen pollution, as well as industrial and smoke pollution. We can well profit from the experience gained in dealing with the water contact and avoid the negative approach of requiring demonstration of injury to health. Positive measures are needed, and again statistical methods must be used in defining and evaluating approaches to control in terms of positive health.

Food Contact

There is certain to be a decided extension of the use of statistical methods in dealing with the food contact. Evaluation procedures now employed lean heavily upon provision of physical means of handling and processing, without adequate supporting evidence of the value of these means in terms of real quality. One of the most pressing needs in food control is the development of more efficient objective measures of quality in terms of end results of food products consumed. There is also certain to be increasing demand for assistance of the statistician in evaluation of nutritional problems.

Industrial Health

Another fertile area for labors of the public health statistician is industrial health. A number of public agencies are now concerned with this problem, while private industry is attempting to deal with the problem on a within-plant basis. The trend is toward integration of effort, both governmental and private, aimed at the total problem. The division between health problems which occur within industry and those which occur in the community is artificial. For example, industry has already discovered that absenteeism from nonoccupational injuries and illness by far exceeds that associated with occupational. The statistician with a public health viewpoint can assist, first, in setting up record systems in industry and in government agencies which will be interlocking and, second, in analyzing and evaluating health problems which have a reflection in production manpower. This should mean not only better over-all community health, but dollars and cents to industry.

Medical Care

A new field, at least in the United States with great potential demand for services of the public health statistician is that of medical care programs. Whether these develop to be public or private programs, the need for assistance from the statistician will be equally acute. Record systems, the definition and scope of programs, the types and number of services, the control of panels and equitable payments by those who receive service and the physicians rendering service, and fiscal and administrative management offer opportunities to the statistician.

Community Planning

A challenge is extended to the public health statistician to participate to a greater extent in community planning, particularly in providing practical long-range population forecasts as a basis for rational design. Every community endeavor is ultimately related to the problem of population change. All of the medical services and environmental controls—hospitals, clinics, water and milk supply, sewerage and

sewage disposal, refuse collection, and housing—are projected on the basis of population.

Although the individual is the basic unit, in practice the planning and administration of these services and facilities is developed on a community basis. Community development requires years in promotion, planning, and construction; consequently, its adequacy depends upon our ability to anticipate future needs. Every index points to a leveling off of population growth from the steep rates of the past toward population saturation. In this transition, estimating future needs becomes increasingly difficult.

Projection of future growth on the basis of the steep midstage rates unquestionably would result in spending vast sums for facilities for which, most probably, no population will exist. Furthermore, such misplaced expenditures would be reflected in shortages of funds for new types of facilities and services needed in the transition to population saturation. Accordingly, it becomes increasingly important to measure and evaluate characteristics of community growth and population change. The emerging patterns of community growth go beyond birth, death, and migration rates to the underlying force of economic opportunity. In a free, mobile society, such as the United States, migration is extremely sensitive to the socioeconomic opportunity offered by a community. Quite aside from biological factors of fertility, the will to have children is also strongly influenced by economic opportunity.

In defining community growth, more than mere consideration of the number of individuals is involved. Some basic questions need to be studied: How old are our cities? What is their limit, their life span? What is their present stage of development and what are the logistic characteristics of their growth curves? Is each community a law unto itself or are there marked common characteristics which are quantitatively referable to underlying forces?

Preoccupation with argument about world population in the mass has often kept the experts from considering the practical down-to-earth needs of the community. It takes courage to venture a population forecast for specific practical purposes for a specific community.

Too frequently, knowledge of all the refinements of population growth drives the expert into the shelter of his ivory tower and robs him of the courage needed to make a clean-cut practical forecast. On the other hand, ignorance too frequently leads to irresponsible boldness and vast expenditures of public funds for under- or over-designed facilities.

These are but a few of the expanding problems destined to increase the demand for services of the public health statistician.

New Statistical Tools

The power and economy of new statistical tools now developing is a potent force in itself, propelling the public health statistician into positions of greater opportunity for service. I venture to predict the future will show that the applications of modern sampling survey methods mark the beginning of a vast new era in public health. As we deal with the more complex social and environmental problems, this modern instrument of the statistician will come into wider and wider use in defining and evaluating progress toward positive public health. For the first time within the grasp of the administrator, there is available an instrument of efficiency in time, cost, and effort which can frequently be employed in measuring community-wide needs, problems, and progress.

Also, through the advances in mechanization for handling mass data, such as the newer electronic machines, it will be possible to undertake massive and complex analyses heretofore prohibitive because of sheer bulk.

This, indeed, is a promising and challenging vista. It is hoped that the administrator, by a better understanding of the power and economy of the statistical tools, will continue to expand their application and to utilize more fully the potentialities of the statistician. The public health statistician must welcome these added responsibilities. He must speak a language understandable to the administrator and the public. He must leave, for a moment, argument concerning refinement of theory and come to grips with practical application. If the public health statistician is to measure up to the challenges ahead, he must take the initiative in offering his services to the entire public health team.

Application of Statistical Analysis In a Health Program

By RUTH R. PUFFER, Dr.P.H.

The statistical program is an integral part of health programs just as are the medical, nursing, and sanitation programs. In fact, the statistical aspects are often so much a part of the administration of a program that it is difficult to separate the statistical from the administrative.

Because of the administrative use of statistics, the statistician works with the health officer, the epidemiologist, the clinician, the nurse, and others in planning and developing programs and in applying statistical analyses for their guidance. This teamwork begins when plans are being made for the initiation of a new program to insure collection of proper data for administrative purposes and for continual evaluation.

Statistical analysis is used here in a broad sense to include records, and collection, processing, and tabulation of data, as well as analysis and interpretation—all essential parts of statistical work. The success of a program may depend on the vision shown when the records are designed. The records must have sufficient data for administration, for evaluation, and sometimes for research. Space must be provided for the data required for analysis. Satisfactory procedures for collection and com-

pletion of the records should be developed in the planning stage. The method of processing and tabulating the data is important. If mechanical means are needed, plans for codes for punching and tabulating are part of the initial planning. Selection of the best method of analysis and of correct interpretation of the results are important phases of statistical work.

In planning the statistical phases of a program, study, or experiment, the specific objectives should be stated and the collection of data directed to fulfilling those aims. The objectives and methods will vary in each program.

Presents a Challenge

The application of statistical analysis, used in the broad sense, to planning, operating, and evaluating a health program differs in every field in which services are provided. No single pattern applies to local health department activities, to work in maternal and child hygiene, to cancer control, and to other programs. Statistical analyses vary from descriptive statistics to applying life table methods to data collected for use in studies of cancer and tuberculosis patients.

The wide range in the kinds of statistical analyses and in their application makes the statistician's work one of the most varied and stimulating in the field of public health. It requires imagination and vision to apply the right kind of analysis and to provide services that will really be useful. The statistician must be ready to make suggestions, to adapt new

Dr. Puffer, director of statistical service in the Tennessee Department of Public Health, presented this paper at the Second Conference on Public Health Statistics, School of Public Health of the University of Michigan, Ann Arbor, June 16.

techniques, and to recommend uses of the results in the improvement of the programs.

In the past, progress in health departments has often been measured by reductions in death rates from communicable diseases and in infant and maternal mortality. However, at present we have only an occasional death from typhoid fever or diphtheria, and deaths from puerperal causes are few. Certainly, we cannot measure the effect of a health department on a population by the reduction in deaths from communicable diseases. New ways of measuring the effect of specific programs on the health of the population are needed. We need morbidity studies to learn the causes of illness and disability in order to develop preventive programs.

All this means a constantly changing and interesting field for the statistician. In Tennessee, for example, our statistical work changes continually, and within a few months we may be involved in new applications that require new approaches. Examples from five fields of current interest will illustrate.

Birth Registration Test

The recent birth registration test made as part of the 1950 census is a good example of evaluation of statistical work and of the accuracy of birth statistics. However, the contribution of this vital statistics work will depend on use of the results in improvement of birth registration—particularly in States and localities.

For the test, the census enumerators obtained information on each infant born in January, February, and March 1950. These records were matched with birth certificates filed through routine registration procedures in all the State health departments except Massachusetts. Preliminary results released by the Public Health Service showed that 97.8 percent of the births in the United States were registered (1). However, there was considerable variation by States. In general, registration was not as complete in southern as in northern States.

All of us from States in which registration is not complete must further define the problem within our States. The percentages of births registered by counties in Tennessee are shown in figure 1. This information has been released in the health department's monthly bulletin,

"The Spotlight," and thus each county registrar knows the problem in his county.

The breakdown of registration according to place and attendant in table 1 supplies further information on why births are not registered. While 99.5 percent of the infants delivered in hospitals were registered, only 91.9 percent of those attended by physicians but not delivered in hospitals and 84.8 percent delivered by midwives were registered.

Table 1. Number and percentage of births registered in Tennessee, by attendant, birth registration test, 1950¹

Attendant	Total births	Births matched	
		Number	Percent
Total.....	18, 476	17, 863	96. 7
Physician, in hospital.....	13, 206	13, 146	99. 5
Physician, not in hospital.....	3, 471	3, 191	91. 9
Midwife, other, not stated.....	1, 799	1, 526	84. 8

¹ Preliminary data from Public Health Service.

Analysis of results from the birth registration test has indicated where registration is incomplete and who fails to register. The next step is to plan and operate a better birth registration program. Many approaches must be used. First, the physicians delivering babies at home and the midwives who failed to register must be shown the value of birth registration so that all births they attend in the future will be reported. All registrars must be aware of the problem and of the ways of checking to insure that all known births are registered. The field agents of the division of vital statistics must aid in the counties where registration is incomplete. If the old tried ways fail, new methods of learning about babies delivered at home must be discovered.

Results indicate that the public does not know the value of birth registration. Therefore, a health education program is needed. A film entitled "A Piece of Paper," referring to the birth certificate, has been developed in Tennessee. This film will be shown to high school

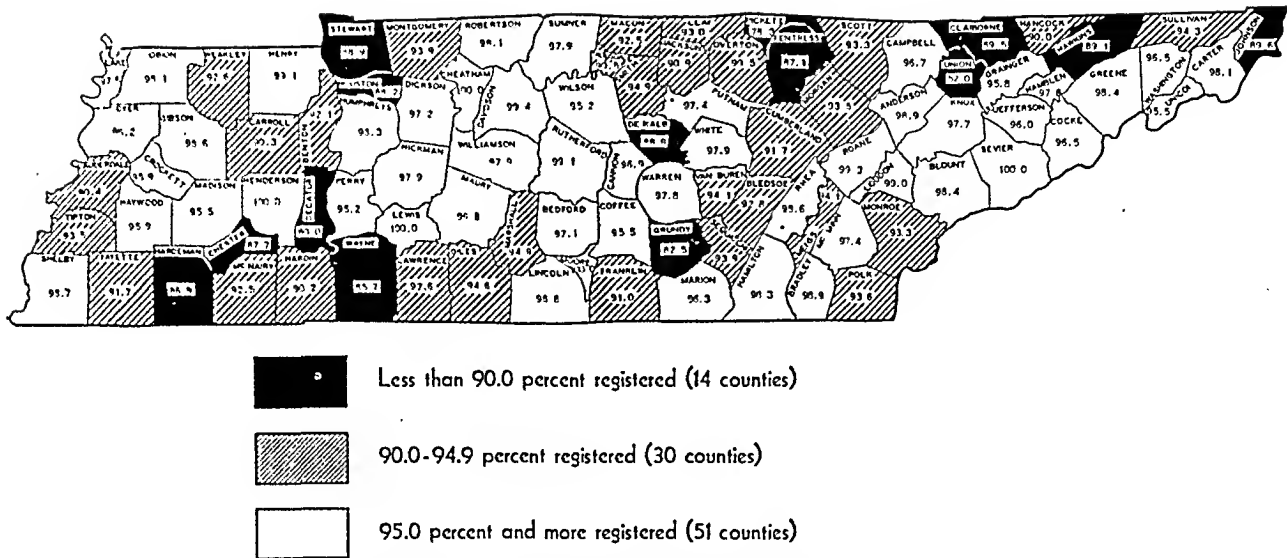

Figure 1. Percentages of births registered by counties in Tennessee, according to preliminary figures supplied by the Public Health Service from the 1950 birth registration test.

students, to parent-teacher groups, at State and county fairs, and to other groups in hope that each prospective parent will know the value of the birth certificate and make sure that each infant is properly registered soon after birth. A pamphlet, "Birth Registration in Tennessee," is also in use in the education program.

Thus, the results of this birth registration test are being applied to planning and operating a program to improve birth registration.

Crippled Children's Service

In Tennessee, statistical assistance is given routinely to the crippled children's service for the administration of that program. A punch card is prepared for each crippled child placed on the register, giving name, date of birth, county, diagnosis, and similar data. A section shows the services and expenditures in a given year. These punch cards are used for preparing the annual reports and for making special tabulations whenever needed by the crippled children's service.

The annual report required by the Children's Bureau of the Federal Security Agency is completed by tabulations from cards of children treated by physicians during the year. In addition, we make tabulations for the director of the crippled children's service to use in evaluating the program. An example is table 2, which

shows that 4,782 children (35 percent on the register) received physicians' services. The expenditures per child vary according to type of crippling condition. The expense per child for cleft palate and harelip was \$93, for club-foot \$51, for rickets \$21, and for burns \$325. These figures are quoted when discussing expenditures with families and with county judges.

In addition to the program evaluation, analyses are made of specific problems and used in many different ways. One example is in the field of accident prevention. When the director of the crippled children's service discussed accident prevention at the Governor's Safety Conference, he stressed the prevention of crippling from accidents. More than 1,000 of the children on the register in 1951 (1,041, or 7.6 percent) had been crippled by accidents. Three hundred and seventy-four children had received severe burns. The expenditures per child were greater for treatment of burns (\$325) than for any other type of crippling.

The number of crippled children on the register per 100,000 population has been studied by counties according to causes of crippling. These case rates are shown by counties for cleft palate and harelip (fig. 2). The higher rates for this condition and for rickets in east Tennessee counties are of special interest to the director of the program, and he hopes to find

the causes of the higher rates in order to develop a preventive program in conjunction with the treatment program.

Speech and Hearing Program

At the request of the director of the speech and hearing program recently established in Tennessee, statistical assistance was given in the design of records, and plans were developed for coding and punching data for children with serious defects. Since the director wished to evaluate case finding by several different methods, tabulations and analyses have been made according to method of case finding (2). Figure 3 shows the results of examination of all elementary school children through mass surveys, and of cases obtained through referral by teachers using symptom sheets and by teachers without preparation.

The mass survey revealed that 8.9 percent of the children had speech defects and 13.8 percent, hearing defects. The percentages were much smaller by the other two methods of case finding. By knowing how successful these various methods of case finding are, the director can decide how best to operate a satisfactory program. Analyses of the work by counties have also been useful in the operational phases. Many decisions have had to be made regarding defects. The need for consistency in

order to develop satisfactory statistical data for analyses has meant review of records and procedures. In a new field such as this, the statistical phases are closely interwoven with the administrative, and continual analyses and

evaluation of results have a constructive influence on the program.

Statistics for Industrial Hygiene

The director of the Tennessee industrial hygiene program wished to know the health problems in industrial groups. Three types of data have been developed and used in that program: (a) mortality statistics by occupation and industry; (b) morbidity statistics through the study of absenteeism of workers; and (c) survey data.

Mortality by Occupation and Industry

Beginning with death certificates for 1944, the occupation and industry given for persons 15 years and over have been coded, using the classifications of the United States Bureau of the Census. The early work we did in this field pointed the way to the improvement and extension of such mortality studies. Many of the difficulties encountered were pointed out in a previous paper (3). Defective though the data were, differences were noted in tuberculosis death rates according to socioeconomic class. The rate for white men in professional work was 26.3 per 100,000 and for laborers 91.7. The National Office of Vital Statistics of the Public Health Service has contributed to the improvement of data on death certificates by release of the booklet, "Guide for Reporting Occupation and Industry on Death Certificates" (4).

Morbidity Statistics

As in all fields of health, morbidity statistics are preferable to mortality statistics for knowledge of health problems. In order to study the health problems of industrial workers, a study of illnesses of 1 day or longer causing absence from work has been carried on in Tennessee. Participating plants report absences to us monthly, giving data on age, sex, color, and cause of illness. Detailed annual reports, prepared for the plants, show frequency, disability, and severity rates according to age, sex, color, and causes of illness. By comparing the rates of a plant with rates of other participating plants and with those of a public utility, the health problems of the plant can be determined. Directors of industrial hygiene and of the sta-

tistical service can then discuss the problems with plant managers, and steps can be taken to improve the health program of the plant.

Marked progress in the reduction of absences due to illness has occurred in participating plants. One plant has given permission for use of its data in discussing industrial absenteeism. The absence rates from illness and injury and from other causes in this plant during 8 years of participation are shown in figure 4. During the first few years of participation, the absence rates were high—especially for causes of absence other than illness and injury. More accurate data have since been obtained. The high absence rates are due to epidemics of influenza. The statistical analyses have been revealing and have been used continually in evaluating and operating the medical program of the plant.

Cancer Statistics

In order to obtain cancer statistics which would aid our program, a study of patients admitted to the cancer clinics in Tennessee is in progress. A summary sheet is prepared in the participating tumor clinics for each patient found to have a malignant neoplasm. The summary sheets are sent to the Tennessee Department of Public Health, where they are coded and punched and tabulations made for an annual report of the clinic. These annual reports give the clinic directors an evaluation of their

Figure 4. Absence rates per 100 employees from illness and injury, and from other causes, in a Tennessee plant, by months, May 1943 through April 1951.

programs through a careful analysis of the findings. They contain data regarding the number and distribution of cases by site, age, race, and sex, by extent of the lesion (localized, with regional involvement, or with remote metastasis), by period from onset of symptoms to diagnosis, and by type of treatment.

The data from all the clinics are combined annually into one report (5). Data taken from the 1950 annual report are given to show how the work is evaluated. The percentage distribution of cancer by site found in patients admitted to the Tennessee clinics in 1950 has been compared with the similar distribution of newly diagnosed cases found in Atlanta, Ga., through the survey (6) of the National Cancer Institute, Public Health Service (fig. 5). The Atlanta study recorded all cases of cancer found by phy-

sicians, hospitals, or by death certificates, which probably gives a good distribution of new cases in a southern community. Of the patients admitted to Tennessee clinics, 30.1 percent had cancer of the female genital organs, and 13.3 percent had cancer of the female breast (accessible sites). In Atlanta, the comparable percentages were lower, 16.3 and 10.3, while cancer cases of the digestive organs constituted 17.8 percent of the group. Thus in Tennessee clinics, cancer of the accessible sites is being discovered. Improvement has been noted, however, in detecting cancer of inaccessible sites, and more cancers of the digestive system and of the respiratory system are being diagnosed. The data show the need for health education and for finding cases in the localized stage. This material is being used by the cancer spe-

cialists, and one of the clinic directors uses the material in teaching medical students.

Each one of these cancer patients is being placed under observation, and his status is obtained at annual intervals from the date of diagnosis. An important part of this study program is to follow each patient and to analyze the results by calculating death and survival rates. Slips are sent to the clinics for the status of patients at annual intervals. If the clinic is unable to locate the patient, the slip is sent to the health department and a field visit is made. Careful follow-up of each patient is essential for analyses.

The method of analysis is the same as that used in the study of the life experience of tuberculosis patients (7). The probability of dying or of surviving is obtained for each year by an adaptation of life-table methods. By this method each patient is considered to be at risk of death for the year, except those for whom the status was unknown. Each of the persons of unknown status is counted as being exposed to one-half year of experience. The cumulative probability of dying during the period of observation is obtained.

Using this method, the probabilities of dying have been calculated for the different clinics by site, race, sex, and other distributions (8).

Figure 6 shows the percentage of the patients diagnosed in 1947 as having malignant neoplasms of the skin, of the female genital organs and breast, and of other sites, who were dead at the end of the first 3 years of observation. During the first 3 years, 19.4 percent of the patients admitted in 1947 with malignant neoplasms of the skin died. The percentages were much larger for the other sites—60.6 percent of those with malignant neoplasms of the female genital organs and 54.8 percent of those with malignant neoplasms of the breast died during the first 3 years of observation. The percentage dying during the first 3 years of cancer of all other sites combined was 69.1.

As we obtain more data, analyses will be made according to site, extent of the lesion on diagnosis, type of treatment, and other variables. However, in order to have satisfactory data for analysis, it is advisable to build slowly and soundly. Procedures had to be established and follow-up has to be well done.

In the field of cancer statistics, the application of statistical analyses to the development and guidance of the program is especially important. The annual reports have been useful in showing the limitations of the Tennessee program and the need of service to patients with malignant neoplasms of inaccessible sites.

Figure 5. Percentage of cases of malignant neoplasms according to site for six tumor clinics in Tennessee, 1950, and for the Atlanta, Ga., area 1947.

Figure 6. Mortality during 3 years of observation of patients with malignant neoplasms admitted in 1947 to five tumor clinics in Tennessee, by site.

Health education is also needed to get patients to clinics when lesions are localized. The analysis of the life experience provides a method of studying the treatment and behavior of malignant neoplasms of the different types and sites. Combining the experience of different cancer clinics with careful follow-up of patients through clinics and health departments will provide the medical profession, as well as health officials, with accurate data regarding survival of patients.

Summary

Several examples have been given of the application of statistical analyses to planning,

operating, and evaluating different types of health services. Applications in five fields—birth registration, crippled children's service, speech and hearing program, industrial hygiene, and cancer statistics—show various ways statistical analyses serve in health programs. The statistical program is an integral part of all health programs for we need data for definition of problems and guidance of programs. Since the programs vary, each health department must decide how statistical analyses can be applied to specific problems. Because of the variety in the applications and the continually changing problems, statistical work provides an unusually challenging field of work.

Current Methods of Collecting Statistics Of Health and Health Problems

By O. K. SAGEN, Ph.D.

The methods of collecting statistics relating to health and health problems are as multifarious as the subject of health itself. The extent and variety of health statistics are limited only by the resources available and the imaginations of those in this work. Although it is impossible to describe all statistical collection methods relating to health, an insight can be gained into what is going on and what may be done by classifying and outlining the principal sources of health statistics.

First, agreement is needed on what is meant by health and health statistics. The word "health" according to the dictionary means "state of being hale or sound in body, mind, or soul; especially freedom from physical disease or pain." The aim of public health efforts is to bring this salubrious state to the general population. The efficacy of the public health effort is evaluated by progress toward that goal. The role of public health statistics is to describe the current state of health, measure its improvement or deterioration, point out salient problems, and provide analytical material for evaluating and guiding the public health effort. Although this definition may seem excessively broad, it is necessary to adopt such a concept to encompass the field of the present-day public health effort and its associated statistical collection methods.

Dr. Sagen is chief statistician at the Illinois Department of Public Health, Springfield, Ill. This paper was presented before the Second Conference on Public Health Statistics of the School of Public Health of the University of Michigan at Ann Arbor, June 16.

Since the health of the individual is affected by his social and economic environment, public health statistics must include a considerable amount of information on the social and economic conditions of the people, as well as the biological aspects of their sickness and health. For this reason, the public health statistician needs to keep in close touch with, and have available, statistics on population, housing, employment, welfare, and related social conditions. These data are not collected and compiled by the public health statistician except as portions of social statistics draw upon data collected in health work, such as the vital statistics of birth, marriage, and death. The public health statistician has the responsibility of utilizing the statistics in these related fields by interpreting and applying them to health problems.

Methods of Collecting Data

There are three distinct ways in which data for health statistics originate: (a) statistics compiled from returns and reports required by law, principally those of birth, marriage, death, and reportable diseases; (b) statistics derived from program activities and operation of health facilities; and (c) survey statistics from which data are gathered purely for the sake of the resulting statistical information. Also, some collections of data may represent a loose combination of types, for example, mobile X-ray screening in a tuberculosis program wherein a survey for statistical data is combined with a case-finding device in the operation of an antituberculosis program.

Collection of statistics required by law has the advantage of legal authority to compel reporting, but it also has certain disadvantages for improving the administrative mechanism and changing the content of reporting. For example, the fact that the registration of births and deaths in many local areas is not in the hands of the health department is an administrative disadvantage. Even one State health department does not have birth and death registration responsibility. The disadvantage of legal specifications for statistical reporting is illustrated by the difficulty encountered with fetal death statistics. In order to extend the reporting to include all products of conception, it becomes necessary to amend the laws in almost every State.

In many instances, statistics originate in official licensure and regulation of various enterprises and occupations. The licensure of medical practitioners, nurses, and other health service occupations affords some statistical information on manpower resources in the field of health. However, more useful information arises from the licensure and regulatory activities over hospitals, nursing homes, diagnostic laboratories, and other institutions from which indications of illness can be obtained through required reporting. In the field of environmental health the licensure and regulatory function is the key to most of the information on the problems of environment. Notable examples are regulation of industrial health hazards; waste disposal; water, milk and food supplies; and housing sanitation. These services are often combined with a health service program, with the service aspect strengthened by the entree afforded by police power, while the law enforcement is facilitated by the persuasive aspects of useful service gratefully received.

Program Data

The proliferation of health services, facilities, and programs in recent years has given emphasis to the development of health statistics and to routine reporting of the statistical data. The administration of the services requires systematic record keeping which in turn generates statistical data. Compilation and analysis of

these statistics become essential in administering, evaluating, and operating the projects, and here the official and nonofficial agencies share common problems. An example is the tuberculosis X-ray screening program in which the voluntary tuberculosis association conducts surveys side by side with the official health department. In this situation the statistics of the activity assume added importance because they provide the basis for coordinating twin efforts which cannot be allowed to clash or to duplicate and overlap each other. In other cases, the voluntary agency will operate the screening venture and the official agency will do the follow-up. Here again, the statistics provide an indispensable link in keeping the project in alignment and in balance.

The operation of health services—to people, to lower animals, or to environmental elements—brings out two competing demands for statistics. On one side is the need for statistics in the administrative work of planning and operating the projects, while on the other the so-called clinical or research statistics are needed to evaluate methodology and reveal new knowledge on the subject of the service. Since competent statistical work is expensive, the resources often are not sufficient to provide both kinds of statistics for the project, and a large amount of data arising out of health service operations is collected but not used, or is improperly handled. Another factor is the shortage of biometricians for work in the health sciences. Despite these limitations important statistical work is being done in the various health services, and utilization of the statistics is on the increase.

The phrase "health services" is used here to embrace the whole area of preventing, mitigating, and remedying disease, disability, and injury. Even this is not sufficient when we think of sources of health statistics obtainable from various insurance plans designed to mitigate economic loss to individuals due to sickness, disability, or death. Life insurance statistics for a long time furnished about the only source of consistent information covering illness and disability for a large part of the population. The experience of the hospitalization insurance and medical care plans has now been added to this source. In these activities, the gathering

of health statistics comes as an essential by-product of the operating records for the enterprise.

As stated earlier, the salient characteristic of the statistics from health services is that the statistical data are derived by a systematic handling and processing of the records used in operating the service. Good records are essential to efficient operation, as well as to reliable statistics. This becomes apparent the larger the service grows and the longer it operates. Health departments have encountered this fact in their experience with case registries for tuberculosis and cancer. However, we must keep in mind that there is a tendency toward over-elaborate statistics from clinical data. A mass of unmanageable data results from trying to assemble every scrap of information. Clinical data are best utilized for specific research studies, with limited objectives carefully planned in advance of collecting the information.

The majority of health statistics arise from cross-sectional data on conditions as they exist at a particular time. Cross-section statistics fail to reveal what goes on in the never-ceasing process of change in people and in their conditions. Studies based on longitudinal data fill that gap by following the course of events in the same group of individuals through repeated observations over a period of time. Fruitful sources of longitudinal data are the health services given for chronic diseases such as cancer, for chronic or recurrent infections such as tuberculosis, venereal disease, and rheumatic fever, and for impairments such as those due to poliomyelitis, premature birth, and dental caries. Also, of equal if not of greater importance are longitudinal studies on persons who are apparently well at the outset. Compared to cross-sectional studies, longitudinal studies are costly if they are made only to complete follow-up. Indiscriminate enthusiasm for longitudinal studies has stimulated too many duplications of effort. For example, it should not be necessary to conduct identical follow-up studies in all cancer programs over the country, yet at one time this procedure was seriously advocated for cancer registries.

Emphasis is now given to obtaining statistical summaries of services provided by health departments, particularly in local health de-

partments which want to know what each of their programs is doing. Many local health departments are keeping count of nurses' visits, of the number of children served by well-child conferences and in school health programs, the number of immunizations given, sanitary inspections and services rendered, and other activities of the local health department. Administrative data of this kind have appeal but are not as useful as they should be since the attempt has been to cover too much territory. The problem of how to use such data effectively in evaluating local health programs is under-going investigation.

The mass of statistics that can arise from conducting health services and programs makes it important that health agencies exercise discrimination in planning statistical work. The primary necessity is to plan how much statistical work will be needed to operate the program effectively and to furnish a simple evaluation of its effectiveness. A decision is needed on what and how much research is to accompany the program and on what the potentialities are for learning something that is both significant and new. This is the joint responsibility of the program director and the health statistician.

Survey Statistics

The survey method of obtaining statistics is the oldest of the three approaches discussed here. In the United States the earliest comprehensive survey was the Federal census of population in 1790. The object of the survey method is to obtain cross-sectional information on the distribution of certain carefully defined characteristics in a population, which may be animate or inanimate, human, or any other species of fauna or flora. For a long time the survey method was restricted to a complete enumeration of the population under study. As a result of the development of statistical theory, we now have techniques for obtaining valid information characterizing an entire population by enumerating only a part of it. These statistical sampling methods are advantageous because of the relatively low cost at which reliable facts can be learned about a large population. The technique also furnishes information on the degree of precision which

can be safely attached to the statistical results. Extending the use of sampling surveys will open a veritable gold mine of knowledge on health conditions. So far, the most notable health study of this kind is the National Health Survey of 1935-36.

The various mass-screening techniques for tuberculosis, heart disease, diabetes, and syphilis; for dental, hearing, and eyesight defects; and for other diseases conducted individually or in combinations as "multiphasic" screening, provide challenging methods for making observations of large groups of the population. The principal object of screening has been case finding and health education so that early diagnosis can lead to early remedial treatment for as many as possible. Statistically, the value of findings in such surveys has not been as useful as desired because the screening applications have been only incidentally designed to yield statistics. If screening projects were conducted so that statistical sampling techniques could be applied, the data would yield information on distribution of the defects surveyed in the general population. Nevertheless, valuable data have been assembled through these screening processes.

It would be futile in anything short of a textbook even to list all applications of survey methods in health statistics. The Public Health Service has perhaps done more of this work than all other health agencies combined. Perusal of a file of *Public Health Reports* for recent years will provide a fairly comprehensive bibliography of the various situations to which survey techniques are being applied.

Quantity and Quality

The sources of statistics sketched are sufficiently comprehensive to indicate that there is no dearth of data on health as far as quantity is concerned. Current methods of collecting health statistics tend to emphasize quantity above quality. Part of this emphasis is due to the conditions which health statistics are called upon to describe and the large populations among which such conditions exist. An unfortunate circumstance is that statistics too often connote mere aggregates of numbers in

tables in which one can search for and find an interesting numerical "fact." Throughout the country health statistics as a whole still suffer from much poor handling of data. Insufficient precautions in assembling data, improper processing, and unskilled analysis produce unusable and misleading "statistics." Year by year we are seeing improvement as the users of health statistics become better informed and as the statistical personnel in health work become more proficient.

State-Federal cooperation is doing much to improve the quality of State and national vital statistics. Current vital data are of a higher and more uniform quality throughout the entire country than ever before in history. The striking increase in the completeness of birth registration for the last decade bears witness to some of this improvement (1).

Health statisticians generally are getting sharper tools and learning how to use them. Great strides have been made in obtaining more uniform and precise methods of classifying original data, which is the first and most critical step in compiling statistics. The general adoption of good classification standards means that our health statistics all speak the same language. The greater use of mechanical equipment and the development of new machines expressly for processing statistical data have shortened the processing time, brought about greater numerical accuracy, and permitted statistical analyses which hitherto have involved too much labor.

The mechanical aids and improved compilation methods do not reduce the need for solid thinking in producing statistics. The object of the entire statistical process is to produce useful conclusions on health problems, conclusions that are valid and simply expressed. This represents an intellectual exercise that cannot be avoided. Current statistical practice applied to health data needs to give greater recognition to this principle if it is to utilize fully and properly the material already available in such abundance.

Statistics in the Administration Of a State Health Department

By JOHN D. PORTERFIELD, M.D.

A recent issue of the *Harvard Business Review* contains an article on the relations between management and professional employees (1). The principal difficulty in these relations seems to stem, according to the author, from three facts: that management and professional employees rarely have the same objectives in view in pursuing their endeavors, that management and professional employees either do not speak the same language or speak different vernaculars of the same language, and that, because of the first two facts, there is considerable blocking in communications between the two.

My observations suggest that much the same factors form the basis of the problem in the use of statistics in public health. It is necessary to strike at the root of these difficulties and to devise methods by which the objectives of statisticians and public health administrators can be reconciled, their languages unified, and their communications made facile and two-directional.

It seems to me that State health departments provide, perhaps more than any other work center, an area in which understanding is too frequently absent and most vitally needed. In speaking for the health officer, may I recite his objectives, indicate his problems, and suggest how statisticians may help him with his solutions.

Dr. Porterfield, director of health of the Ohio Department of Health, presented this paper at the Second Conference on Public Health Statistics, School of Public Health of the University of Michigan, Ann Arbor, June 20.

Why a State Health Department?

Although 48 versions could perhaps be obtained on the reasons for the existence of a State health department, I offer my concept.

Standards

The first objective should be to determine standards of performance and achievement. In most instances, by State law, the State health department has the responsibility for establishing a minimum code or body of regulations which must be met by the local health units within the State however far beyond them their own inclinations and abilities may lead. Even where a minimum code is not a statutory requirement, the State health department is in the best position to develop and establish goals for the local health units of that State.

These standards may be as exact and measurable as the values of sensitivity and specificity requirements of an approved serologic laboratory or the number of days of isolation to be imposed upon a specific communicable disease. They may be as intangible—in our present knowledge—as the optimum time of a home nursing visit or the best ratio of public health personnel to population served. And they may be anything between. The State health department should have the time and the highly trained personnel to devote to investigation, to testing, and to determination of a set of values which can be used as a guide by local health units in meeting their community problems.

This activity of a State health department is not restricted to the formation of a State sanitary code containing the minimum require-

ments or standards of laboratory performance and communicable disease control. It includes the positive approach to a set of desirable values covering the whole range of local health unit operation—financing, staff, program content, methodology, and achievement. These desirable values may not always be set out as requirements, but they serve a useful purpose as bench marks.

Local Assistance

The second objective of a State health department, in my concept, is to assist local health units in meeting these standards. The methods of such assistance are legion and include such things as guidance, consultation, the exchange of information, the provision of highly specialized or expensive personnel and facilities for periodic or continued cooperative use of local health units, financial assistance in the way of supplementation of local budgets with either State or Federal grants-in-aid, and finally, and least exploited to date, the objective analysis of the current performance and achievement of local health units in comparison with State averages and with the standards developed by the State department.

Direct Service

The third objective I put last intentionally. The department must perform those direct health services for the population of its State dictated by the statutory charges made by the State legislature. While there is wide variation from State to State in these assignments, it is becoming more capably demonstrated every year that direct services of a State health department should be confined to the type of work that can be done more effectively on a state-wide than on a community basis.

There probably are not too many of these services. One example of the type of program which is not too susceptible to delegation as a local health unit responsibility is water pollution control. This work must generally be done in terms of drainage areas since streams and rivers have given little thought in their meanderings to the local jurisdictional lines that may be crossed. Control of surface water pollution is not quite as closely distributed in population profiles as is, let us say, communicable disease

control. There may be other and perhaps even more appropriate instances of direct health services which can be better performed by State health departments than by local health units. But their number is limited.

Use of Statistics

If these, then, are the reasons for the existence of a State health department, how can statistics be used in meeting these objectives? It seems apparent that the first objective, the determination of standards, must depend heavily upon the use of statistical tools and the proper treatment of the proper data to arrive at satisfactory conclusions and recommendations. Scientific research in the sense of establishing new knowledge in the scientific field is probably not a primary function of a State health department, although there are some that indulge in this activity to a greater or lesser extent. Applied research certainly is necessary, and the most neglected field of applied research is in administration methods. Granting that a program director knows intimately the scientific details of the field wherein he works, there is still considerable room for investigation into methods by which scientific knowledge can be used to help the population aggregates which have the problems.

Obviously, it is necessary at the very beginning to measure the extent and distribution of the public health problems. Just as obviously, the trial and error method of developing satisfactory solutions to these problems is expensive and time consuming. Knutson in *Public Health Reports* has presented articles on the pre-evaluation of proposed health education programs (2, 3). This is a type of study which cries for extension to the other special areas of public health.

An indispensable feature of investigations leading to recommended standards is the development of reasonably precise methods of measurement which can be applied to the observations made. The venereal disease control officer may know that the epidemiological work of contact tracing and examination is as important as the treatment of diagnosed cases of infectious syphilis. But to develop a standard for performance of this phase of the program,

he must join his knowledge of the epidemiological ramifications of syphilis with the statistician's ability to plan for accumulation of valid and uniform data if he is to be able finally to recommend that at least one contact be found and examined for every case diagnosed. Note that this standard is not purely the outgrowth of his epidemiological knowledge but is tempered by the findings of the statistician as to what common experience and achievement are.

In any development of standards, it is necessary that a continuing process of comparison of the current standards with results achieved must be maintained so that the standards are not alone ideal, but are also practical and attainable. This process cannot be accomplished without the initial development of means of data collection and result measurements. And, finally, under this heading, it is a necessary but too often forgotten requirement that continuing data collections after the original establishment of standards be at the minimum essential for proper control and should never be above the minimum purely for data collection. Only a statistician and a program chief in complete cooperation can make those determinations.

Problem Measurement

That brings us, of course, to the second objective—the assistance of local health units in meeting the established standards. Here we must have careful and current problem measurement—not only natality and mortality, but also the causes of mortality and the measurement of morbidity. We must have effective means of comparing performance with the standards, remembering that not only performance, but also the standards themselves can change. And we must have some measurement of the effectiveness of methods used in our programs. Examples in practice are the percentage of yield in case-finding programs and the comparison of cases reported with deaths reported from specific cause.

A State health department has or should have a considerable body of consultants—who spend their time consulting. Now a consultant's visit is always valuable to a local health unit if he is able to bring the news, the trials and errors and solutions of other units with similar prob-

lems. The visit is valuable if the consultant has the proper and adequate amount of training, experience, and ability to communicate so that his fund of knowledge is useful to the local personnel. The visit is twice as valuable if the suggestions and recommendations are framed to the specific problems, needs, and resources of the unit visited. And this double value can be provided if the consultant has had the opportunity before the visit to review the proper data collected from the unit and the analyses and interpretations which have been made of the data.

One of the most effective means of drawing a local health officer's attention to the needs of his tuberculosis control program is to show him the ratio of cases found to cases first reported by death certificate. We have found it to be impressive when we can show a local health officer not only his area's infant death rate compared to the other areas of the State, but also the distribution of deaths by age during the first year of life. It helps him to determine whether further reduction of the rate requires emphasis on improved obstetric care, hospital nursery care, or home care. It makes a big difference whether his logical move shall be to stimulate physician education or to increase his postnatal visits and emphasize his home sanitation program.

Should the State lend its much demanded and expensive mobile X-ray unit and team for 2 weeks to a completely rural county whose tuberculosis case and death rate has been the lowest in the State for years? If instead the time is allotted to an urban area with higher rates, will the value of the loan be enhanced by arranging for the unit to concentrate on those census tracts containing the lowest economic groups with crowded substandard housing even though the percentage of population screened is less than it would be if the service were directed to the well-regimented children of a co-operative school system? These questions can be answered when the proper data have been collected and properly analyzed.

In most public health programs we have passed the shotgun stage where we can do an unmeasured but vast amount of good by firing blindly out of any window. We are now in the marksman rifle stage. Particularly with our

strained budgets in these high-cost days and with our almost permanent limitation of trained personnel, we must make every shot count. As we approach our solutions of public health problems, our target becomes ever a more closely defined one. And statistical analysis is, to continue the metaphor, our rifle sights.

Fiscal and Administrative Data

During the last several years Ohio has attempted to develop a basic formula to be used in the distribution of Federal grants-in-aid reallocated to qualified local health units. It was felt necessary that such distribution should be as objective as possible and should be guided only by pertinent factors such as population, financial need, public health problems. Such a formula has been devised and is being used, and, while the change to this system has caused difficulties, the ultimate system promises to be good. The important point is that the administrative people found themselves depending heavily upon the statistical people for this formula development. An even more important point is that the statistical people have discovered a rich field of inquiry in the governmental financial structure. This is not as far removed from the field of public health as it would seem, and it is certainly an area of keenest interest to the local health personnel.

While we may hope some day our investigations will suggest some sound answers to Ohio's budget questions, we have already foreseen another question begging solution—how to measure the effect, both psychological and program-wise, of Federal assistance. Foundations have for years pondered this question. I am not sure their tentative findings will be ours.

Statistics in Direct Services

Statistics aid the direct services of State health departments in the same way they do the local departments. In justifying a new program, the problem must be measured in size, in distribution, and in internal structure. The new program should be pre-evaluated, and the running controls of performance and achievement must be established with preparation of the most efficient data collection and analysis

mechanisms. Existing programs should periodically rejustify their existence and test the effectiveness of their methods. In Ohio, we have just finished reviewing the results of a small program on high nitrite concentrations in private water supplies. The percentage of private supplies showing significant concentration was too low to warrant the continuation of routine chemical laboratory tests. Related data showed little evidence of human effects and suggested that the judgment of the sanitarian in the field as to the circumstances surrounding the private supply was a better guide than laboratory tests and entailed no extra costs. We have stopped, therefore, doing routine nitrite tests on water samples from private supplies.

While statistical services to local units may be considered in great part educational, a direct service of the statistical unit to its own department is as a more formal educational resource. The close union of the State health department and the department of preventive medicine of the State medical school, where circumstances permit such alliance, is mutually beneficial. A respectful appreciation of quantitative medicine implanted in the minds and hearts of medical students will produce a healthy skepticism in the youthful reader of professional literature. It will in time improve the quality of such literature, and, not least, it will encourage understanding of community medicine, of disease reporting, and of kindred matters in a future ally—perhaps even a future colleague in the specialty.

Vital Statistics

The final role of statistics to be mentioned here is the traditional statutory one of the State registrar. There must be collected and preserved appropriate records of births, stillbirths, deaths, adoptions, legitimations, marriages, and divorces. In this connection, there must be close supervision of the functions of local registrars. The State registrar has gone far in perfecting his duties and his methodology. What remains in many places is the activation of his mine of information for more than the regular annual report. Many, if not most, of the program chiefs of the department will find

much in the registrar's data of concern to them in program planning.

The Biometrics Unit

The statistical or biometrics unit must naturally be under the direction of an experienced biometrician. We have had accomplished statisticians from other fields who find too much difficulty in understanding the problems and needs of the program chiefs. The biometrician must be capable with statistical tools, must have a reasonable understanding of the content and modus operandi of public health programs, and must have a sufficiently fluid imagination to develop means of applying his techniques to the subject.

The unit must have sufficient numbers of statistical clerks to handle the daily load of routine work. Some say this should be a mobile work force capable of assignment to whatever job is in present demand. Others point out the advantages of specialized statisticians or clerks within the unit, assigned more permanently to the work of particular programs. There is something to be said for both sides, and that decision is yet to be reached. The unit should, if possible, have a graphic artist, one who can translate into understandable visual aids the technical charts and tables.

Somewhere in the department there will be a machine-tabulating force, and almost always there will also be a clerical record-keeping unit to handle what the machines do not. Both of these facilities, if not in the biometrics unit, should be so closely associated as to avoid any gaps, either physical or mental.

The location of the biometrics unit in the State health department is a topic I approach with some hesitation. I do not know the answer. Some day I hope to. Certain principles must guide us, but the decision in any State depends ultimately not only on adherence to these principles, but also on the personalities involved and their relative abilities.

The principles are these: that the only purpose of organizational structure is to facilitate function and that the intradepartmental relations must therefore be based on services given

and obtained between various units in the structure. In Ohio, we have occasionally followed this practice: When the major portion of services goes to one major division of the department, the service unit is placed in that division and from there provides its lesser services to other divisions; when services are distributed fairly evenly to a number of major divisions, the service unit is located in the administrative center of the department, whether it be called the division of administration, the bureau of central services, or what.

Certainly, program chiefs and the biometrics chief should have direct access to each other. The only intervening factor may sometimes be a referee, one who can settle questions of priority and service distribution, particularly where resources are limited. The biometrics chief deals with each program chief, with the office of local health services in the correlation of services to local health units, and with the office that devotes its attention to research and to standards development.

In serving local health units, while biometrics goes through the office of local health services, it should go all the way through and actually visit local health units. It will do both sides good in understanding their common objectives. Occasionally, personnel of the biometrics unit may be the specialized personnel mentioned before who may be placed on temporary assignment to a local health unit to help in the establishment of a new record system or for other special problems.

The biometrics unit should have a fair degree of autonomy to pursue all these aims. But through the medium of staff meetings or planning conferences, it should be kept in close relation to the body of which it is a part. It will have outside relations, on the one hand with local health units, and on the other with the National Office of Vital Statistics and the epidemic intelligence group of the Public Health Service. With these latter Federal agencies, the unit will develop and maintain its functions in collecting and forwarding its share of national data for analysis and will in return look to these resources for consultation and assistance in special studies and problems.

As health officers and statisticians work

closely together, the similarity of their objectives will become more and more apparent. As we continue to confer, we will learn each other's idiom and our communications will be perfected. Out of the potpourri of disparate training we will get in public health a new generation with broad understandings and widened abilities.

Vocational Rehabilitation

Successful employment last year for 2,600 rehabilitated young civilian men and women with heart disease set a new record, the Office of Vocational Rehabilitation of the Federal Security Agency recently announced. The previous record was 2,300.

The average age of the worker in the group of 2,600 was 17 years when the disability became evident and 26 years when vocational rehabilitation was started.

At the beginning of the rehabilitation, 2,316, or 89 percent, of these men and women were unemployed. Forty-six were working on farms or helping with family work. Wage earners in jobs dangerous to their health numbered 288. The average wage of the working group was \$1,577. After vocational rehabilitation, 2,427, or 94 percent, were earning a yearly average of \$2,133. The remaining 158 were doing farm or family work for which no record of earning was available.

A new record was also set in rehabilitating into productive employment 5,696 men and women with hearing disabilities. About 1,500 of these persons were deaf, and 4,200 were hard of hearing.

Of particular significance in the rehabilitation program for the deaf was the extreme youth of the group, indicating that the State rehabilitation agencies are reaching many young people of school age and getting them ready for work before they run into job-finding difficulties that usually beset people who cannot hear. The average age of this group, 90 percent of whom were out of work when help was started, was 25.

Three out of five of the hard of hearing were out of work, and practically all the others were in danger of losing their jobs or were in unsuitable work. Their average age was 39.

As a group, the rehabilitants with hearing difficulties increased their earnings from about \$2.3 million a year to more than \$10 million the first year, an increase of 344 percent.

The Administrative Value of Statistics To a Local Health Officer

By BERWYN F. MATTISON, M.D., M.P.H.

In medical school teaching, at least, biostatistics is usually associated with the school's department of public health and preventive medicine. One might almost say that statistics is "blamed on" the public health physician. And yet, with a few outstanding exceptions, little really useful information has been available to show health officers the quantitative relationships between morbidity, mortality, population characteristics, and public health services.

Kinds of material available include: crude birth and death rates; specific mortality rates for a few communicable diseases; reported case rates for a few diseases; and from some State offices of vital statistics, annual figures on population characteristics (usually from the most recent Federal census)—age, race, sex, and occasionally marital status—on rather broad geographic area breaks.

Also, most public health administrators have provided themselves with total health service figures for: public health nursing visits; type of care supplied—tuberculosis, infant, ante-

partum, bedside care, or general health supervision; and similar figures for sanitation personnel activities in terms of total inspections by type of establishment.

Unfortunately, the cross relationship of health services to population served, or associations of differing population patterns with differing specific mortality or case rates were usually missing. Nor were the sanitation inspection figures usually related to the total need in terms of the number of institutions of the various types inspected and results attained in securing abatement of violations for any particular inspection unit.

Perhaps I am unduly skeptical, but I have found that local health officers initiate very few new health programs. Health programs are usually either inherited—witness those in tuberculosis, child health, venereal diseases, communicable diseases, sanitation, and public health nursing—or are thrust upon the health officer by some higher authority. Civil defense, cerebral palsy, and municipal water fluoridation are typical programs.

This does not mean that original contributions in administrative public health cannot or should not be made from the field. It does imply, however, that most of the original contributions made by local health departments are in terms of changing service programs through a continuing evaluation of their effectiveness. In a local area, this results in shifting emphasis from one part of a public health program to another, rather than in a summary abolition of old programs or initiation of new ones. Hence, the vital necessity for consciousness of quanti-

Dr. Mattison has been commissioner of health for the Erie County (N. Y.) Health Department since its organization in 1948. The county department provides health services for the cities within the county, including Buffalo, as well as the townships. This paper was presented at the Second Conference on Public Health Statistics, School of Public Health of the University of Michigan, Ann Arbor, June 20.

tative factors in both program control and evaluation.

Local Area Statistics

There are several ways in which vital statistics and health indexes can be used to improve program control. For instance, mortality figures can be brought down to a local area, even in a large city. In Buffalo, N. Y., the only figures originally available were the State mortality rates for the entire city. The health administrator needs more information than that. He can use rate groupings by census tract or by ward units to point up the problems of control, since they vary as much within the city as they vary from county to county, or from State to State.

Mortality data by local area and similar information about reported morbidity and current population patterns—age, sex, race, economic status, crowding, family size, marital status—serve as a firm basis for shifting sanitation and nursing personnel where they are most needed. The map of Buffalo shows the relationship of the child population, as determined by birth rates for census tracts, to the frequency and distribution of well-child clinics. Only by combinations of such information can our limited facilities and services be utilized to their maximum advantage.

Nor is it sufficient to have only the geographic distribution of morbidity and mortality facts. They must also be put in their proper relationship to chronology. These patterns vary too and certainly must be anticipated by the health officer in allocating vacations and other shifts of personnel service within each calendar year.

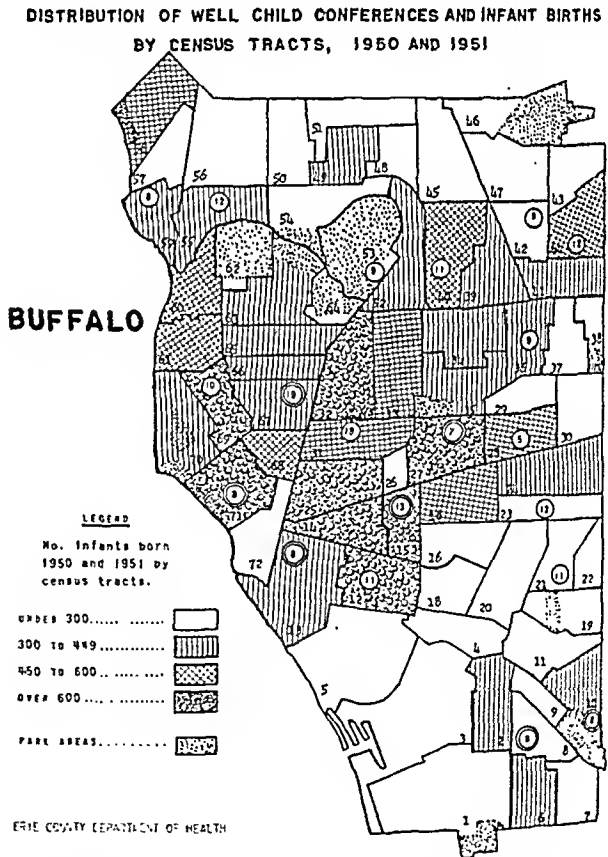

Program Planning

Sometimes a little advance planning, together with a consciousness of the requirements of certain basic data in the analysis of any health problem, converts the routine procedure into a most valuable fact-finding operation.

Smallpox Epidemic

A few years ago, a small but sharp outbreak of smallpox occurred in New York City. Both within the city and in its suburban areas, a

large number of vaccinations and revaccinations were performed in order to block the further spread of the disease. In one community nearby, the health department performed approximately 30,000 immunizations. This meant somewhat frenzied activity on the part of the small department for a few days. However, plans were made for the return of approximately 10,000 vaccinated persons for reading and interpretation of their vaccination reactions. Also, schedules were prepared for completion at the time of their return. The schedules provided information on age, sex (race was omitted as unimportant), date of last vaccination, if any, and other relevant facts. Thus, after the smoke had cleared away, the results of revaccinations on more than 8,000 individuals, when tabulated, provided informa-

A desirable use of local statistical data is illustrated in the above map prepared by the Erie County (N. Y.) Health Department. Similarly, a handbook of maps for Buffalo and Erie County (by census tracts, by wards, or by townships) shows mortality data by cause of death and other statistical data as well.

tion about the duration of immunity, at least insofar as it could be measured by the vaccination reaction, that was unknown before.

Poliomyelitis Season

Another use of existing records as well as special study records may be mentioned in connection with the policy of banning immunizations during the poliomyelitis season in New York State last year.

From a field study, it was found that children over 6 months who had received immunizing injections in a period preceding a poliomyelitis outbreak had definitely higher attack rates of the disease than children not so injected. On this basis, it was recommended that no immunizations be given to children of that age during the summer months.

Little attention was paid to the fact that the absolute number of cases of poliomyelitis occurring during the second half of the first year of life was extremely small.

In Erie County, N. Y., we were concerned about the possible effect of this policy on our diphtheria control program. So we inquired further: first, so far as poliomyelitis was concerned, how many children could have been affected by this change in immunizing procedure if the new policy had been in effect during the preceding two epidemics in this area; second, how much loss of actual immunizations against diphtheria was associated with the new policy.

By checking poliomyelitis reports for the two preceding epidemics, we found that only 11 out of 500 cases (or about 2 percent) had occurred during the first year of life. Thus, if as many as 50 percent of the cases in that age group contracted poliomyelitis because of the former policy of immunizing through the summer months, then not more than 1 in 100 cases could have been affected by eliminating the immunizations.

Diphtheria Immunizations

Following the poliomyelitis season in 1951, we kept close check on attendance at our immunization clinics and well-child conferences during the remainder of the fall and early winter. A review of these records for a district of more than 110,000 people indicated that not only was there no compensatory increase in at-

tendance at either type of clinic following the season, but that the total figures lagged noticeably behind those of the preceding year. Actually, instead of the 413 diphtheria immunizations given at the clinics in 1950 between July 1 and October 14, only 81 were given during the same period in 1951. According to our 1951 policy, all were children under 6 months. A total of 332 children past that age failed to receive protection during 1951 who might have been so protected if the 1950 immunization rate had prevailed in 1951. When we considered the failure of the compensatory increase during the fall months, there was found to be an over-all decline of 58 percent in total immunizations given in our clinics for that district during the interval from July 1 to November 30, 1951, as compared to the same period in 1950.

Because of these considerations, we have liberalized our current policy for completing immunizations of infants under 1 year of age. Season will be disregarded—at least in the absence of a definite epidemic of poliomyelitis.

Program Control and Evaluation

Apart from vital statistics and health indexes, another group of records which form the basis of quantitative program control and evaluation is the health service records in a local department of health.

Nursing Records

For many years, we have used the State public health nursing service records. These are based on daily and weekly service records and are hand-tabulated by each nurse every month. This was time-consuming. Two years ago, we changed over to a "mark-sense" card for reporting each nurse's daily activities. No hand tabulations of these cards are necessary; they are turned in at the end of each month for machine-sorting. The greater flexibility of this system is obvious. It eliminates the clerical time formerly required of each nurse. It also makes possible rapid and accurate monthly analyses of activities in each subdistrict, and periodically, for supervisory purposes, a detailed analysis of each nurse's case load. Best of all, it makes possible the occasional spot-checking of

different activities not ordinarily recorded in detail.

In each of these special analyses we obtained more data about our nursing services and about the individuals served. Some of the special sorts made during the past year include an individual case count and a count of individual families receiving nursing service; accident information in homes visited; details of arthritis case visits; and nursing and physical therapy services given to cerebral hemorrhage patients.

It should be noted that all public health nursing service records, as well as all sanitary inspectors' service records, are kept according to census tracts so that services can be related to population and environment.

Sanitation Records

Until the past year, sanitary inspection records were chiefly listings of visits without any particular relation to the total size of the problem. Our figures now, however, show the number of places by type (hotel, boarding house, etc.), as well as the number inspected each month. Provisions are made for measuring, to some extent, the effectiveness of each service. To do this, we changed from weekly service records, which were hand-tabulated at the end of each month, to a daily time sheet indicating type of establishment, type of activity, and the time involved, together with a mechanical punch card prepared in the biostatistics office to which material is transferred directly from the daily time records after coding by that office. Here again, a great deal of clerical time is saved, and a much closer relationship can be established between type of service given and the total problem in each area.

Value of Records

Another example of the value of complete and usable service figures can be mentioned. In one district, shortly after the establishment of our relatively new county-city health department, the "undue amount of time spent in conference" was locally criticized. It was true that members of the public health nursing service, formerly without adequate supervision, required intensive in-service training at first. This meant many conferences and some addi-

tional travel time in bringing the staff to the central office for training. However, analysis of the records showed that the increased conference time paralleled an increased utilization of field service time, which was indicated by the number of nurse visits per 100 hours of duty. This point was immediately accepted, and criticism ceased.

One of the unmet needs of administrative program control and evaluation is the further development of ways for relating the efficiency of services to changes in health indexes. In spite of all of our vital statistics and service record figures, little has actually been done to relate the two.

Program Indexes

One outstanding exception, in New York State, is the venereal disease control program. It has developed program indexes which are most useful. We have the number of cases of early syphilis reported each year and the proportion known to be under treatment. We have the number of new cases of early syphilis interviewed for contacts and the number of contacts named. We know the number of previously unreported cases of syphilis discovered among the contacts named. We also know the proportion of reported cases under treatment that have been observed for at least a 12-month period after treatment. Many of these indexes give fairly simple checks on the effectiveness of field procedures in use from day to day.

Unfortunately, indexes for other programs are not so well developed as in venereal disease control. In tuberculosis control, we know the number and classification of reported cases and the mortality rate by age, race, and area of residence. But there are many relevant factors and associations which are not usually available.

Tuberculin surveys to determine infection rates in different age groups are sporadic rather than routine in most communities. In Erie County, N. Y., we spot check elementary and high schools to determine the rapidity with which children in those age groups are becoming infected, but we have little information about the pattern of infection either in the preschool group or in the age groups beyond

high school. We assume that factors like crowding and other housing conditions are intimately associated with the spread of and mortality from tuberculosis. And yet, with the exception of mortality and case-report rates by census tract, little of this relationship can be clearly quantitated.

An attempt is under way in Buffalo to get basic nutrition data by surveying selected school-population groups for early stigmata of nutritional deficiencies. That information, when it is complete, may possibly be related to the factors of crowding, annual income, family size, and tuberculinization to give us a better idea of the mechanics of tuberculosis spread.

Of course, it is now possible, with the final information available from the 1950 Federal census, to show the relationship between some of those social factors and the occurrence of various chronic diseases. Much more needs to be done. For instance, in Erie County we are attempting to describe quantitatively the fate of minimal cases of tuberculosis picked up asymptotically by survey methods and to compare them with the fate of minimal cases picked up in our clinics after they have sought care because of symptoms. Basic physiological differences such as this in the host-parasite relationship cannot be lost sight of in making administrative decisions as to the effectiveness of special programs.

Health Patterns

The shifting age pattern of poliomyelitis epidemics is well established. The relationship of that change in age pattern to sanitation, housing, crowding, and similar social factors is less well understood. Similarly, we are only beginning to be conscious of the real significance of delaying infection from poliomyelitis and other communicable diseases until they affect groups having higher mortality and more crippling defects. It is easy to shut our eyes to the fact that our efforts in sanitation, let us say, may be actually neutralizing our efforts in communicable disease control, if we think in terms of resultant mortality and crippling. Yet these associations can be quantitated too.

During the past 15 years, there has been a marked drop in the maternal mortality rate in

New York State. Recent analyses show that two plunges in a downward trend occurred in 1936 and 1946. The first has been attributed quite properly to the introduction of sulfa drugs and to a sharp decrease in the component deaths from puerperal infection. The second interruption has been attributed by some to the more widespread use of antibiotics and blood or blood substitutes. But let us go beyond the patients to the population.

Since World War II there has been a sustained increase in the birth rate; a lower age at first marriage; a lower age at first childbirth; and a disproportionate increase in the average number of children born to better educated and higher economic groups. All of these factors would tend to decrease the maternal mortality rate as they would bring more and more births into experience groups which we know to be associated with more favorable rates. Without detracting from the importance of the antibiotics and the greater availability of blood transfusions, I submit that we must always consider the denominator as well as the numerator of our changing health indexes.

Program Promotion

Another administrative use of statistics by the local health officer beyond planning, control, and evaluation is program selling or promotion. To the local health administrator, it is useless to know what programs are desirable for his community or how effective they can be unless he can persuade the community of the need for such programs and get financial support.

Statistics can play an important role in this phase of our responsibility. First, refer to the chart which illustrates the services available to one district (Lackawanna) within Erie County before and after the institution of the county-city unit there. By simple bar diagrams, the comparison of services and costs was brought home so forcefully that this one chart alone played a definite role in quieting criticism and obtaining acceptance of the new organization in that particular area.

Meeting Criticism

Another example of program selling is the approach to answering criticism of our crippled children's program. The State medical rehabil-

itation program system for approval of qualified specialists giving services to crippled children was thought to be unduly restrictive. A few physicians in the community were doing most of the work for county and State programs, it was said. An analysis of our records demonstrated that the criticism was without foundation. The services provided by 46 physicians cost from \$237 to \$915 a case, according to type of service. Findings of the children's court showed that less than 10 percent of the parents were able to pay part or all of the costs of special surgery.

The value of surveys should also be men-

tioned. A recent survey of approximately 1,100 Erie County physicians by the Western New York Committee for Education on Alcoholism revealed that a great preponderance of the responding Erie County physicians believe the educational program of the committee, during the past 3 years of operation, brought more chronic alcoholics under medical care. The survey also indicated a real recognition on the part of the practicing physicians of the need for further education on alcoholism. Eighty-eight percent of the respondents said the need is important, and gave the committee a convincing argument for local community

HEALTH SERVICES INCREASE IN LACKAWANNA DURING THE PAST THREE YEARS..

Display of the above chart picturing comparative costs for selected health services in Lackawanna, N. Y., contributed successfully to the acceptance of a new city-county health department in Erie County, N. Y.

chest support. This kind of argument is obviously more telling when backed up by the quantitative opinion expressed in a survey than when it is merely the subjective opinion of a few individuals.

Appraising Exhibits

The health exhibits appraisal made by our office of health education at the county fair has been most useful to us. Devised as a method for improving exhibit materials at the fair, the appraisal consisted of a time study, a professional evaluation, and a visitor preference poll. The microblood diabetes detection booth was by far the most popular service program with individuals going through the fair's health building. Here again, as in the alcoholism survey, quantitative information covering hundreds of visitors polled was more impressive when brought to the attention of sponsoring agencies than any number of theoretical considerations. Again, the continued financial support of the diabetes detection program may be related to the survey.

Use of Statistical Services

Statistical services at the local level can be provided by a trained biostatistician or by an office of biostatistics utilizing all grades of statistical training, beginning with the untrained junior clerks, but under the supervision of a trained biostatistician; and by other personnel with graduate training in public health who should have had some foundation in statistical techniques. Recruitment of personnel for statistical work at the local level is necessarily difficult unless the local health department is situated near and working closely with a university offering some courses in statistics. In-service training, at least in mathematical statistics, is usually difficult and probably not feasible. However, many of the functions of collecting basic statistical data—the registration of births and deaths and reporting of morbidity—can be handled by statistical clerks, who benefit greatly by such in-service training.

State-Local Relationship

What statistical services should be supplied by the State department of health? Whether the local department is large or small, there are

standards of uniformity which can be supplied only from the State level. Reporting of disease and death and birth registration should be standardized by the State health department. Frequently, this is not simple. Querying of death records may occur at four levels—the local registration district, the local health department, the State health department, and the Federal agencies. Only by agreement on forms, coding, and procedures can this information be standardized.

Few local health departments have either the statistical machinery or the funds to purchase mechanical statistical services. Yet most of them have, either on an annual or accumulative basis, masses of vital statistics, of service records, and of other quantitative information from which much more could be learned through machine analysis if available through the State agency.

The statistical division of the State department of health should provide consultation services on special problems in the local health district. These problems might be in the setting up of record forms (where statistical advice should always be sought), on the planning of field studies or surveys, and wherever possible, on the localization of morbidity and mortality figures on census tract or other small unit bases.

Related to this, most local departments must depend upon the State office of vital statistics for intercensal population estimates, without which localization of service record figures and other vital statistics can mean little.

The State biostatistician can help in still another area by assuring some degree of uniformity to the state-wide vital statistics reports. This would seem to be self-evident, but too often from year to year the tabulations available are not directly comparable with preceding tabulations, either because of different table arrangements, different population breaks, or different age groups.

The Local Biostatistician

In most instances, the State health department is the only training ground available for local health department biostatisticians. This does not mean that experience with the State unit necessarily qualifies the beginning biostat-

istieian for local health work. There should definitely be a two-way interchange between local and State health units for the beginning biostatistician to see the problems as well as the advantages to be met at both levels. Some functions are best performed at the local level. Death certificate querying is a point in illustration. The local health administrator knows his physicians personally and knows the hospital record room personnel. Because he is familiar with local medical teaching practices, he is much better equipped to obtain the basic death data than someone miles away who is less familiar with the local situation.

Similarly, most work with local service records can be done only in terms of the local administrator's knowledge of what goes into the records. However, in training as well as in the other areas of cooperation between local and State departments, effectiveness of any joint activity will depend on the degree of understanding and acceptance of each department by the other.

Finally, there are at least four basic ways in which the well-trained biostatistician can help the local health administrator. First, he can improve the quality of basic vital statistics and service data available locally by guiding in-service training and hospital staff indoctrination on birth, death, morbidity, and service reporting. Second, he can extend the scope of morbidity occurrence data by guiding local morbidity surveys of nonreportable disease and health conditions. Third, he can encourage the most effective use of statistics and quantitative thinking in the local department of health by constant participation in staff conferences, through consultations with other staff members, and by promoting the use of optimum methods of collecting and handling available data. Fourth, he can strive toward the development of service-yield indexes by working with the field staff in providing ways of relating service figures to appropriate yields in improved social factors related to those local service activities.

The problem of communications is important if each member of the health team, including the biostatistician, is to contribute his utmost whenever possible. To make such contributions possible, the opportunity for communication must be provided.

It is the health administrator's responsibility to bring together, systematically and frequently, the program directors, the field supervising group, and such staff specialists as the biostatistician, the health educator, and the personnel director. This we do in Erie County through monthly division and bureau conferences—seven in all. There is no excuse on either side to plead ignorance of the mutual opportunities for working together. Demonstration of needs—and help in meeting needs from both directions and over a lengthening period of time—point up the value of staff conferences.

Conclusion

The local health officer finds it most important to relate vital statistics and health services, not merely to geographic areas, but according to the characteristics of the people living in those geographic areas.

Statistical services can serve as program aids—in planning, control, evaluation, and promotion.

Because statistics are intrinsically quantitative, it is easy to overlook the quality or validity of base data. A continuing effort should be made in the local health department to broaden the scope and improve the accuracy of these base data.

More work must be done to demonstrate measurable relationships between disease and social factors. These relationships are part of the anatomy and physiology of a community, which, with its prevalent pathogenic parasites, may determine the community's pattern of health and disease.

The Medical Entomologist in Public Health

By E. HAROLD HINMAN, M.D., Ph.D., M.P.H.

In the period from 1897 to 1920, before the birth of medical entomology as a scientific discipline, the greatest discoveries in the role of arthropods in the transmission of human diseases were made by physicians, pathologists, bacteriologists, and others who had no basic interest in entomology. In 1879 Manson, a physician, discovered the part played by mosquitoes in the development of the filarial worm and later developed the mosquito theory of malaria transmission. Ross, another physician, tested this theory in 1897-98, and had his results confirmed promptly by British and Italian workers. Theobald Smith, a pathologist, with Kilbourne, in 1893 demonstrated that the cattle tick was the intermediate host of Texas fever of cattle.

In 1900 the American Yellow Fever Commission, consisting of Reed, Carroll, Lazear, and Agramonte, demonstrated the role of mosquitoes in the spread of yellow fever. In the early twentieth century, the role of fleas as vectors of plague was determined by Simond in 1898; of mosquitoes in the transmission of dengue by Graham in 1902; of ticks as vectors of relapsing fever by Ross and Milne in 1904; and Rocky Mountain spotted fever by Ricketts in 1906; and of body lice in the transmission of epidemic typhus by Nicolle et al. in 1909. The role of sandflies in pappataci fever and oroya fever, of

mites in scrub typhus, and of deerflies in tularemia followed promptly. Most of these discoveries were made by physicians, pathologists, or bacteriologists, who "skimmed the cream" off the available knowledge of these arthropod-human disease relationships. Meanwhile, the entomologist was concerned primarily with the life history and control of various arthropods, but was rarely called upon, even as a consultant, in the prevention of these particular diseases.

Medical Entomology, 1920-41

The two decades preceding World War II may be looked upon as the time of serious development of medical entomology. The parent science, entomology, had achieved some maturity by 1920, and in the United States such universities as Cornell, Minnesota, and California, with strong departments of entomology, had already established special courses in medical entomology. This gradually provided the nucleus of a small group of trained workers. The Bureau of Entomology (U. S. Department of Agriculture), the Public Health Service, and a few experiment stations employed an occasional entomologist for the study of vectors of human or animal diseases. A few special research institutes, such as the Gorgas Memorial Institute, retained a medical entomologist as a full-time staff member. The Rockefeller Foundation also employed a few medical entomologists. The Tennessee Valley Authority followed suit a number of years later.

Health departments were much slower than Government organizations and private foundations to accept the entomologist as a useful member of their professional team. In the United States, Dr. L. L. Williams, Jr., of the Public Health Service, developed the idea of a special

Dr. Hinman is dean of the University of Puerto Rico, San Juan, P. R. He was formerly director of the School of Public Health, University of Oklahoma, Norman, Okla. This paper was read by title at the meeting of the health officers section of the Southern Branch of the American Public Health Association, Baltimore, Md., April 17, 1952.

malaria control division in each of the southern State health departments and entomologists were given a prominent place. A group of engineers, entomologists, and medical officers were trained in malaria control during the summer of 1937 at the Rockefeller Foundation Malaria Station in Tallahassee, Fla., the Bureau of Entomology and Plant Quarantine (U. S. Department of Agriculture), the Public Health Service, and the Tennessee Valley Authority for employment in southern State health departments.

During these two decades, a great mass of medically important taxonomic, ecological, biological, and control data on arthropods was assembled. Three textbooks, by Herms, by Matheson, and by Riley and Johaunsen, appeared in the United States. Numerous monographs and serial publications attest to the productivity of workers in medical entomology during this period. The Fourth International Congress of Entomology, held at Ithaca, N. Y., in 1928, had a section devoted to medical and veterinary entomology. By 1941 the science had truly come of age and the medical entomologist was recognized as a specialist by his fellow entomologists.

Despite these evidences of progress in establishing medical entomology as an important specialty, I seriously doubt that, with the exception of malaria control organizations, the average public health worker felt any spirit of kinship with the medical entomologist.

Another noteworthy exception to the recognition of entomological contributions was the utilization of entomologists in connection with mosquito abatement districts. Legislation in 1904 in New Jersey declared the mosquito to be a pest and directed boards of health to abate it. In California the law providing for the mosquito abatement districts was passed in 1915. In most instances these programs were directed against pest mosquitoes.

Medical Entomology, 1941 to Date

World War II drastically changed the status of the medical entomologist as a member of the health team. The Sanitary Corps of the Division of Preventive Medicine, Medical Corps of the Army, eagerly sought not only medical

entomologists but general entomologists and even individuals with relatively little entomological training. Much of the early major fighting was in areas where malaria was often a greater problem than the enemy. Entomologists in research organizations also responded and were able to improve insecticides as well as techniques for the control of body lice, anopheline mosquitoes, and various other arthropods of medical importance. These newer tools gave the field man an opportunity to demonstrate the worth of entomologists. The Public Health Service, in discharging its responsibility for sanitation around military installations, organized the malaria control in war areas program. Its great success, plus the national downward trend in malaria cases, led them to embark upon an extended program and, subsequently, to undertake the national 5-year eradication program. The success of these campaigns may be ascribed in a goodly measure to the capability and devotion of their entomologists. Other notable malaria control campaigns, such as the *Anopheles gambiae* programs in Brazil and Egypt, and the programs in Venezuela, Sardinia, and Cyprus, have been planned and successfully executed due to the major contributions of entomologists. The yellow fever riddle (urban vs. jungle fever) was solved in a great measure by entomological and epidemiological investigations.

In the past 10 years the entomologist has made just as amazing progress in the laboratory as in field control operations. The screening of many thousands of substances for insecticidal, larvicidal, or ovicidal properties has not only developed new toxicants and formulations but also new "assembly line" techniques for rearing arthropods in the laboratory and for developing important new biological data. Anyone who has not visited the Orlando laboratory of the Bureau of Entomology and Plant Quarantine, or the Technical Development Services of the Public Health Service Communicable Disease Center in Savannah, has missed an opportunity to become acquainted with the ingenuity and industry of medical entomologists.

The Future

Some four or five years ago there was considerable sentiment among certain public health

workers, whose reputation placed them in the category of so-called elder statesmen, that DDT, BHC, and possibly some undiscovered insecticides would spell the doom not only of malaria, but probably of most other arthropod-borne infections. I was informed that there was no future in malaria control or in medical entomology.

As more adequate testing and large-scale control programs got under way, the potency of DDT and other toxicants was attested to; however, a number of problems, some of them administrative and some apparently due to the fact that arthropods have not "read the book," have lead us to the conclusion that the panacea is still not yet available.

Resistance to DDT was first noted in houseflies, then in culicines, subsequently in anopheline mosquitos, and later in body lice and in several other species of public health importance. This development of resistance to insecticides impresses upon us the need for more detailed studies on the physiology and general biology of disease vectors by the entomologist.

I believe it is now generally recognized as only a temporary illusion that residual sprays alone would permanently eradicate malaria or any other arthropod-borne disease. Certain biological factors can usually be found to account for the inadequacy of residual sprays, such as unusual resting habits and development of resistance. However, I believe the newer toxicants have more firmly than ever established the need for the medical entomologist.

The extensive routine adoption of the use of synthetic toxicants in the control of household or premise pests of man has tremendously increased the possibility of introducing poisonous materials into the food or drink or air taken in by man or his animals. The frequent opportunities for human contact with these materials has emphasized the importance of entomologists trained in toxicology.

Another development that may be anticipated in the future, on the basis of recent trends, is an increased interest in the role of arthropods in transmission of such diseases as encephalitis, Q fever, tularemia, and plague, and in the part played by muscoidean flies and roaches in the transmission of salmonellosis and shigellosis. Because of these trends, I feel confident that

medical entomologists will be sought after and will continue to play an important role in public health along with other workers in that field.

Administrative Problems

In the evolution of public health work, emphasis originally was placed upon the control of epidemics. Gradually other communicable disease control activities began to receive more attention. In all of this work, physicians properly assumed leadership. It was also quite natural that doctors of medicine in public health should turn to able nurses in this program. As the role of the environment became better recognized, sanitary engineers and other sanitation workers established their positions in health departments. Public health laboratories had to be organized to execute a program of communicable disease control and environmental sanitation. Health education later became a "respectable" aspect of the public health program.

Medical entomologists are really the "Johnnie came lately" people in public health. The 1937 organization of malaria control teams placed them in State health departments for the first time. But had not the MCWA and its extended program and the CDC eradication program evolved, the entomologists probably would have completely disappeared even in the southern State health departments. Originally, a malaria division was established either in the bureau of sanitary engineering or as a part of the division of epidemiology. Because the practical application represented control of the environment, the medical entomologist usually ended up under the administrative direction of the State sanitary engineer. In the current transitional stage of the malaria eradication program, the entomologist is holding his own since the problem is largely one of surveillance. In one southern State health department, a subdivision of entomology has been organized within the division of sanitary engineering and is responsible for licensing and supervising pest control operators. In another State health department, a separate bureau of vector control has been established within the division of environmental sanitation. This bureau in 1946 was given the responsibility for the administra-

tion of a \$400,000 subvention for local mosquito abatement work. Whether this pattern of placing pest mosquito control under supervision of State or local health departments will be widely adopted is not known because certain experiment station programs have become deeply involved in mosquito abatement. Similarly, the supervision of pest control operators has varied in its administrative allocation. In any event, the interests of the State health departments must be recognized in both disease control and environmental sanitation.

Training for Health Work

In a few of the branches of our Federal service, we find a sharp demand for the highly trained and specialized medical entomologist. I believe this will rarely be the case in State or local health departments. In the latter, there is much more likely to arise the need for a well-trained biologist with some special emphasis in

medical entomology, in rodent ecology, in herpetology, in limnology (for stream pollution), in snail ecology, and in parasitology. The organization of the biology section within the Southern Branch of the American Public Health Association was a long-delayed recognition of the important contribution that biologists have made and are making in public health. Health departments below the Federal level have placed much greater emphasis upon operations than upon research. They have long worked upon the principle of teamwork and demanded versatility of the members of the team. If medical entomology is to make its maximum contribution in public health, its representatives will probably need to participate in vector control (rats included), in aquatic biology in connection with stream pollution problems, in pest mosquito control activities, and may possibly need to represent the health department in relations with commercial pest control operators.

Public Health Nursing Study

A study to determine the amount and kind of nursing services required to meet minimum public health nursing needs in local health departments was begun recently by the Division of Public Health Nursing, Bureau of State Services, Public Health Service. A 17-member committee, composed of national leaders in public health nursing, specialists in social research, and State and local health officials, is serving in an advisory capacity.

The study is attempting to answer such basic questions as (1) how much additional nursing service is needed in the rapidly expanding defense areas; (2) how can the available nursing supply be "stretched" to meet increasing needs; (3) how can practical nurses or other aids be used most advantageously in public health programs. It will supplement the over-all functional study being made by the American Nurses Association.

The shortage of nursing personnel, particularly public health nurses, has reached the acute stage. The presently accepted ratio of one public health nurse for every 5,000 population would require an additional 17,500 nurses. To supply 1 nurse for every 2,000 population, a ratio which has been suggested to meet increasing needs for nursing care of the chronically ill and aged patients, 40,000 to 50,000 nurses would be required.

The Tuberculosis Problem

By RUSSELL E. TEAGUE, M.D.

In almost all of its aspects, the rapidly changing picture of the tuberculosis problem in the United States presents one of the most profound sociobiological phenomena, if not the most interesting development, in the entire field of medicine and epidemiology. It is significant, if not paradoxical, that, as many aspects of the disease decline or diminish at an accelerated rate, the program for control continues to expand.

Decline in Infection Rate

Results of tuberculin tests of sample populations in Philadelphia in 1949 seem to indicate that today individuals are being infected with the tubercle bacillus at an average rate of less than 1 percent per year, or one new tuberculosis infection per 100 person-years of life.

Data from three studies at the Henry Phipps Institute in Philadelphia bear out this observation. In these studies, children in three large high schools were tested at 10-year intervals—in 1929, 1939, and 1949. In 1929 the average rate of conversion to the first test dose of tuberculin was 5.3 per 100 person-years; in 1939, this rate was 2.7; and in 1949, less than 1. At the average age of 16 years, in all three studies, the percentages of children who were positive to the first test dose of tuberculin were: 1929, 84 percent; 1939, 43 percent; and 1949, 16 percent.

Dr. Teague is secretary of health, Commonwealth of Pennsylvania. This paper was presented before the forty-eighth annual meeting of the National Tuberculosis Association in Boston, May 27, 1952.

If conversion to the first test dose of tuberculin indicates acquired tuberculous infection or exposure to the tubercle bacillus, the average individual living in Philadelphia under the 1929 rate would have had a new experience with the tubercle bacillus at least three times during his life, whereas if he had lived under the 1949 rate, the chance that he would not be infected at all would be about 50 percent.

It is being recognized and widely accepted that evidence of infection—a positive tuberculin test and especially a recent conversion—becomes more helpful and significant today than in the past. This is true from the viewpoint of the epidemiologist, the diagnostician, and the therapist.

Morbidity

A compilation and preliminary analysis of tuberculosis reports from the States, recently prepared by the Division of Chronic Disease and Tuberculosis of the Public Health Service, provides a source for morbidity data for 1951.

According to this report, 118,414 new cases were reported in the United States in 1951. Although this figure may not be final for the year, it represents a decline of less than 3 percent from the number reported for 1950, and 12.3 percent from the 1947 total. The average annual decline in reported cases since 1947 is 3.07 percent per year.

In view of the intensified case finding during this period, these data are encouraging. The reported case rates for the white and the non-white cases were 68.1 and 165.3 per 100,000 population, respectively. For white and for non-white males the respective rates were 86.6 and 194.8; for white and for nonwhite females, 49.9 and 136.1.

There were four new cases reported in 1951 for each tuberculosis death reported, an improvement in the ratio when compared to 2.8 cases per death in 1947, 3.1 in 1948, 3.4 in 1949, and 3.6 in 1950. The case-death ratio remains higher for whites than for nonwhites and higher for females than for males.

Mortality

In 1950 there were 33,577 deaths from tuberculosis, or 2.3 percent of the total deaths from all causes for that year. Compilations of the total number of deaths reported for 1951 have not been completed, but, based on a 10-percent sample study made by the National Office of Vital Statistics, Public Health Service, the decline in the number of deaths from tuberculosis from 1950 to 1951 was about 11 percent for the country.

The number of deaths from tuberculosis, as well as evidence of infection and morbidity, is dropping faster in the younger age groups and in females than in older males. In 1952, 75 percent of the population of many sanatoriums were males, most of them in the advanced age group.

Longevity of Pulmonary Tuberculosis Patients

My recent life table study of the longevity of all clinic patients diagnosed as having active tuberculosis at the Henry Phipps Institute in the 20-year period between 1926 and 1945 indicates that the average longevity of these patients is 5.9 years. While the whites lived 11.2 years, the average length of life of the nonwhites was 3.5 years.

The cases diagnosed in the minimal stage averaged 25.1 years of life after diagnosis, those in the moderately advanced stage, 9.9 years, while those diagnosed in the far-advanced stage averaged only 1.1 years.

There was no difference in the case fatality rates when the number of cases in the first 10-year period was compared with those in the latter 10-year period. With recent improvements in therapy, however, marked improvement in the case-fatality rates of the patients diagnosed in 1952 would be expected.

Despite the improved picture of the disease, activities directed toward meeting the problem continue to increase.

Case Finding

In 1951, reports indicate that about 13,000,000 chest X-rays were made by States and by the agencies reporting to them. This amounts to 8.2 percent of the total population of the country. In three States the number of X-rays taken amounted to more than 20 percent of their population last year.

Recent studies on familial susceptibility and resistance emphasize the importance of heredity in epidemiology and point out that in the future case finding may very well be directed toward continued medical supervision of the blood relatives of known cases, wherever they may reside.

Isolation and Treatment

Since the prevention of this disease is directly proportional to the number of patient-days of effective isolation, it is encouraging that more beds are becoming available each year for tuberculosis patients. More chest surgery and chemotherapy should eventually result in shorter periods of hospitalization and thereby permit more beds for more patients.

The problem of isolation of the "good chronic" patient has not yet been solved in most areas, and agencies and health administrators are concerned with this problem to an increasing degree.

The management of the recalcitrant infectious patient is being met in many areas by compulsory isolation procedures, and there is evidence of more widespread application of these techniques.

Public health administrators and sanatorium superintendents are plagued with a shortage of personnel, especially nurses, and the trend toward using nonprofessional aides is increasing.

Rehabilitation

Rehabilitation programs for tuberculous patients have not been developed universally.

With a few outstanding exceptions, this part of the problem is yet to be expanded generally.

Immunization

Three States have provided a BCG immunization program for medical students, nurses, and children of infected families. A number of other areas are using vaccination on a more limited basis. The wide-scale use of mass BCG vaccination will undoubtedly be limited to those parts of the world where infection is high and other facilities for control are limited.

The Future

In recent years advances have been made in the fundamental knowledge of tuberculosis in the fields of pathology, bacteriology, immunology, epidemiology, public health techniques, therapy, genetics, and social services, and the total expansion in the whole field of tuberculosis research is heartening. Barring a national catastrophe, it is not illogical to assume that in one more generation the "great white plague" will no longer be a major public health problem in the United States, but this does not mean that we can ever relax our vigilance.

On the other hand, the prevention program must be intensified. Then education of the layman will be more difficult and it will cost much more to find the unknown case, but there will be less expense for tuberculosis hospital beds, and more institutional space will be available for isolation of the "good chronics" that re-

main. More attention will be paid to the hereditary factors in infection. Greater efforts will be given to preventing the entry of tuberculous patients from parts of the world where high rates prevail, and concern may be expressed about the danger of our unexposed, tuberculin-negative population even visiting in areas of high infection. This concern may not be justified and only further studies will give the answer.

Children With Heart Disease Aided

The third in a network of such services in the country, facilities at the Children's Memorial Hospital, Chicago, Ill., will be used to aid children with serious heart conditions, such as "blue babies" whose condition can be helped by surgery, through a special grant by the Children's Bureau of the Federal Security Agency.

This facility will serve Michigan, Ohio, Kentucky, Minnesota, Wisconsin, Indiana, North Dakota, South Dakota, Nebraska, Iowa, Kansas, and Missouri. Illinois already provides service for children under their crippled children's program.

Two other such centers are already in operation in Connecticut and California. Other programs are planned in the East and Southwest.

Group Chest X-ray Examinations And the Tuberculosis Death Rate

By PHILIP ENTERLINE, B.B.A.

The rapid increase in the number of group chest X-ray examinations as a case-finding procedure is one of the interesting postwar developments in the field of tuberculosis control. During 1946, about 6 million X-rays were taken in the United States for the detection of chest disease, excluding chest X-ray examinations by the armed forces and the Veterans Administration (1). In 1950, comparable information submitted to the Division of Chronic Disease and Tuberculosis of the Public Health Service indicated that about 15 million X-rays were taken. The geographic distribution of mass chest X-ray activities, and the apparent relationship between the intensity of these activities and the striking decline in the tuberculosis death rate during this period are reported here.

Since July 1947, a semiannual tuberculosis report (PHS 1394 TB) has been requested by the Public Health Service from each State health department and the District of Columbia for the 6-month periods ending in December and June. These reports give the number of individuals examined on mass radiography projects in each State and the District of Columbia. Mass radiography projects are defined as "any group X-ray examinations, including contacts, regardless of the size of films, taken for the purpose of detecting pulmonary pathology, but not for the identification of pathology or deter-

mination of activity." The instructions further state that "medical examinations, including X-rays taken in the offices of private physicians or in clinics for the purpose of final diagnosis of tuberculosis or determination of activity, are not to be included."

Because of reporting difficulties within the States, the information actually reported probably understates the true totals in many instances. The magnitude of this error is impossible to calculate, and the data shown here should, for the most part, be considered as minimum estimates. Crude estimates were made for a few periods for which reports were not received or for which a report indicated that a sizeable area of the State was omitted. In some instances, the necessary estimates were obtained from local publications, while in others they were based on reports for preceding or succeeding periods.

Relative Intensity of X-ray Activities

Figure 1 shows the number of X-ray examinations estimated and reported for the years 1946 through 1950. The 1947 figure is an estimate based on reports received for the last 6 months of that year, while the figures for later years are essentially those actually reported. During the period 1946-49, the number of examinations increased by about 2.5 million each year; from 1949 to 1950 the increment was about a million.

The table summarizes data reported by each State during the 3½-year period ended in December 1950 and, in addition, shows aggregate information for nine geographic regions. The

Mr. Enterline is assistant chief of the program analysis section, Division of Chronic Disease and Tuberculosis, Public Health Service.

total number of X-rays taken in the United States was 44,000,000, with an average of about 12.5 million per year. Column 3 of the table shows the average annual percentages of the population X-rayed in each State and the District of Columbia, and in each of nine regions. For the United States as a whole, an average of 8.6 percent of the population was X-rayed annually, while for individual reporting areas the average ranged from a high of 26.5 percent for the District of Columbia to 1.5 percent for

Idaho. States with a fairly high average annual percentage of their population X-rayed during this period include: Minnesota, 16.8 percent; Florida, 16.5 percent; Colorado, 15.3 percent; and Washington, 25.7 percent.

The figures shown for the percentages of population X-rayed annually may be overstated somewhat because some persons receive more than one X-ray during a single year. However, since it is generally recommended that chest X-ray examinations be made annually, it is un-

¹ Groupings by the U. S. Bureau of the Census.

² From semiannual tuberculosis reports (PHS 1394 TB).

³ Civilian population estimated as of July 1, 1949, from current population reports, population estimates, series P-25, No. 47, U. S. Bureau of the Census.

⁴ Death rates, tuberculosis (all forms) from Vital Statistics of the United States, part I, 1947.

⁵ Bulletin of the National Tuberculosis Association, September 1951. (A 10-percent sample of the death certificates by the National Office of Vital Statistics yielded the same rate for the United States (22.2) for 1950.)

likely that the number of repeat X-rays is very great in any one year. Moreover, the extent to which the percentages are overstated is probably about the same from one State to another, so that direct comparisons would seem valid.

X-ray Activities and Death Rate Decline

From 1947 to 1950, the tuberculosis death rate (all forms) dropped from 33.5 to 22.2—a decline of 34 percent. This is the largest percentage drop recorded for the United States during any 3-year period since 1921. The only greater percentage drop ever recorded was for the years 1918-21 when the tuberculosis death rate (all forms) dropped from 149.9 to 98.6—a decline

of 35 percent. The 1918 rate was abnormally high, however, and the 1947-50 drop is probably the more significant one.

It would be difficult indeed to isolate any single factor responsible for this favorable experience. Historically, fluctuations in the decline in the tuberculosis death rate have shown little association with the development and application of any new public health techniques and therapeutic measures. Certainly, improvements in housing and general living conditions have been of major importance and may be largely responsible for the postwar decline in tuberculosis deaths. Improvements in case finding, resulting in earlier discovery of the disease, as well as advances in therapy, also have no

doubt contributed to the decline in the death rate as evidenced by the steady decrease since World War II in the percentage of persons discharged from tuberculosis sanatoriums because of death (2-4).

There appears to be some relationship between the intensity of case-finding activities in each of the nine geographic regions tabulated and the decline in the death rate in those regions. This relationship is shown graphically in figure 2. Where the average annual percentage of the population examined was greatest, the percentage decrease in the death rates tends to be greatest as well. (The simple correlation coefficient is 0.800. This is statistically significant at the 1-percent level.) Conversely, where the average percentage is smallest, the decrease tends to be smallest. Although this might appear to suggest that the decline in death rates is attributable to X-ray activities, this is not necessarily true. Both may, in fact, be a result

* Estimated

Figure 1. Chest X-ray examinations in the United States, 1946-50.

of treatment facilities, standard of living, or over-all health department activities.

When the relationship between the number of X-rays taken and the decline in death rate is studied by States rather than by regions,

some of this association disappears. This is largely because in such a comparison the less populous States receive the same weighting as

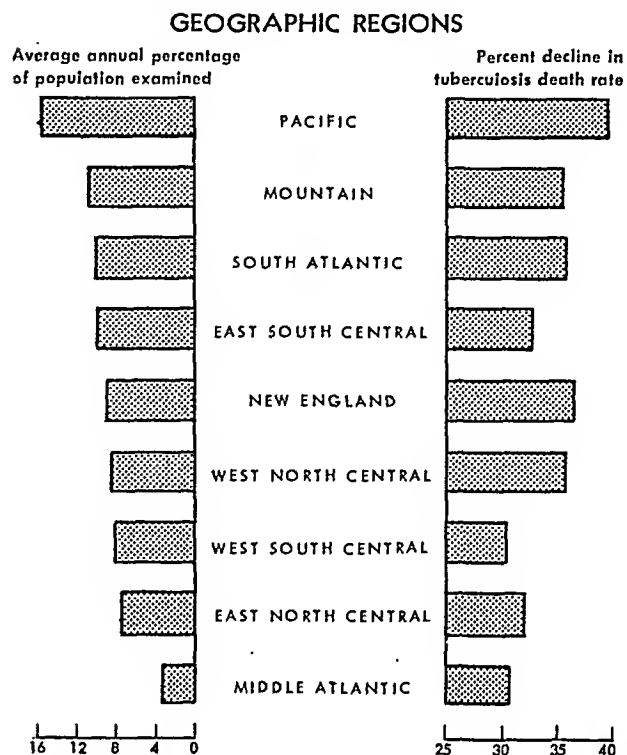

Figure 2. Average annual percentage of population examined and percentage decline in tuberculosis death rate, by geographic regions, 1947-50.

the larger States, and because an unusually great number of these smaller States either had a small percentage of the population examined and a large drop in mortality, or a large percentage of the population examined and a small drop in mortality. More homogenous areas than States are therefore needed for analysis—hence, the use of regions in this report.

Summary

1. The number of chest X-ray examinations in the United States increased from about 6 million in 1946 to 15 million in 1950.
2. On the average, about 8.5 percent of the population of the United States was examined by X-ray during each of the years 1947 through 1950.
3. When data are studied by geographic region, there appears to be a positive relationship

between the emphasis placed on chest X-ray activities and the decline in the tuberculosis mortality rate.

* * *

Reports thus far received for 1951 show a considerable decline in the number of chest X-ray examinations. Probably only about 13 million were made—a decrease of 2 million as compared with 1950. This decrease was greatly accelerated during the last 6 months of 1951, with the total number of examinations for that period nearly 1.5 million below the total for the corresponding 6-month period in 1950.

Prevalence of Tuberculosis in the United States

Current estimates place the number of active tuberculosis cases in the United States at 400,000. Of this number 150,000 are undiscovered.

These figures replace the half-million estimate, widely used during the past decade, which was based on tuberculosis mortality data. The new estimate is based upon the findings of chest X-ray programs throughout the country, plus an inventory of tuberculosis cases registered with local health departments. A joint committee of the National Tuberculosis Association and the Division of Chronic Disease and Tuberculosis of the Public Health Service prepared the new estimate.

Recent chest X-ray surveys of adult populations (15 years of age and over) have revealed approximately one active case for every 1,000 examinations. Since there are approximately 110 million adults in the United States, the committee believed that there were probably at least 110,000 undiscovered active cases of tuberculosis. The upward adjustment of this 110,000 estimate to 150,000 was based upon the belief that estimates from surveys tend to understate

the true prevalence of undiscovered tuberculosis and to compensate for the omission of the active cases in the population under 15 years of age.

Information available from health department case registers in all parts of the country—operated under widely varying conditions and representing about one-fourth of the population of the United States—indicates that for the country as a whole there are records for about 250,000 active tuberculosis cases. This figure, when added to the estimated 150,000 undiscovered active cases, yields the 400,000 figure.

In addition, the committee estimated that there are 800,000 important inactive cases of tuberculosis in the country, 550,000 of them currently undiscovered. This estimate was also based upon the findings of chest X-ray programs and an inventory of tuberculosis cases registered in the United States.

The current estimates released by the committee are summarized as follows:

	Total	Known	Undiscovered
Total -----	1,200,000	500,000	700,000
Active -----	400,000	250,000	150,000
Inactive -----	800,000	250,000	550,000

Public Health and Medicine

At the Crossroads

By HERMAN E. HILLEBOE, M.D., M.P.H.

In these days of disorder, change, and impending disaster, we who are dedicated to the health and welfare of the people face tasks of greater challenge than we have ever known before. We have arrived at a stage in our social development, whether desirable or not, at which the people turn to us increasingly for aid and guidance. This is a grave responsibility. Under its burden and facing its humane demands, we are compelled to review the adequacy of our guiding principles.

Public health is at the crossroads. We must now choose the direction that we shall take in the future, or it will be chosen for us.

The concept of health department services to the people has undergone dramatic change. Advancing medical knowledge and public health activities have sharply decreased morbidity and mortality from the communicable diseases. Improved working conditions, better nutrition, more attention to preventive medical services in the schools, and similar social forces have contributed to improved health and welfare. Environmental sanitation programs are well on their way. Means have been provided and successful methods have been developed for the expansion of environmental health activities.

It is plain that, in the future, the theory and practice of public health must be expanded to

include a vigorous attack upon the chronic diseases, with special attention to heart disease and cancer, which are the principal killers and disablers in our Nation.

We need new knowledge, new methods, and new measurements for evaluating our programs. As the demands of communicable disease control continue to decrease, we must utilize our acquired skills in combating the ravages of the chronic diseases, an increasingly crucial problem for the private practitioner and the public health physician.

Death Rates: New York

Where do we stand in New York State? The 1951 death rate from all causes in the State was 10.5 per 100,000 population. The death rate has never been lower. In 1940 the rate was 11.1. The degree of improvement is greater than these figures indicate. In the last decade the proportion of older persons, among whom mortality is inevitably high, has increased. Had the age distribution of the population in 1951 been the same as in 1940, the death rate would have been 9.2 instead of 10.5.

Infant mortality, 23.7 per 1,000 live births, was the lowest ever experienced and represents a drop of 36 percent since 1940. In the same interval, neonatal mortality decreased 28 percent, while that between 1 month and 1 year dropped 55 percent. Maternal mortality, 4.9 per 10,000 live and still births, also dropped to a new low record and was less than one-fifth of the rate in 1940.

New low levels were reached in 1951 by deaths from streptococcal sore throat (including

Dr. Hilleboe, commissioner of health for the State of New York, presented this paper at the first general session of the forty-eighth annual health conference of the State of New York, at Lake Placid, June 4, 1952.

scarlet fever), whooping cough, and diphtheria. Deaths from streptococcal sore throat numbered 21 as contrasted with 107 in 1940. Deaths from whooping cough numbered 11, while in 1940 there were 138. Only two deaths were attributed to diphtheria; the previous low mark of nine occurred in 1944.

Among the diseases to which all ages are subject, the death rate per 100,000 population for 1951 in New York State, including New York City, was 4.0 for syphilis and 23.5 for tuberculosis. The death rates for these two human scourges were lower than ever before in our history. Indeed, the tuberculosis death rate for 1951 showed a drop of 9 percent over that of the preceding year and was 50 percent less than the rate in 1940. In this 11-year period, the tuberculosis death rate in New York City dropped 46 percent—from 54.4 to 29.5. In the rest of the State, the reduction was 50 percent—from 33.7 to the 1951 rate of 16.7.

Contrast these low rates with the awesome death rates of 184.4 from cancer and 459.8 from heart disease. To state them another way: 43 of every 100 deaths in upstate New York were due to heart disease; 17 out of every 100 deaths were due to cancer; and 11 out of every 100 deaths were from intracranial lesions of vascular origin. It is estimated that 1 out of every 20 persons in the United States suffers from some disorder of the cardiovascular system; every other death after the age of 45 years is caused by heart disease.

Cardiovascular Diseases

Public health epidemiology has made distinct contributions in the field of the cardiovascular diseases. The causes of beriberi, scurvy, and pellagra were elucidated almost solely by epidemiological methods—these methods contributed much to the understanding and prevention of heart disease associated with nutritional deficiencies. Again, the aggregation of rheumatic fever in families and the probable importance of hemolytic streptococcal infections in precipitating heart attacks were discovered largely by epidemiological studies.

In spite of these memorable advances, we seriously lack epidemiological knowledge of many types of cardiovascular disease. Our in-

formation concerning the prevalence of cardiac ailments is limited to selected fractions of the population. The causes of atherosclerosis, hypertension, and rheumatic fever are still unknown. Epidemiologists would be greatly aided in their study of the etiology and demography of cardiovascular diseases if public health workers could devise and test mass methods of screening the adult population for these diseases. Their use in large population groups would give us valuable data on the extent of the problem, and would enable us to bring large numbers of early cases under the supervision of family physicians.

Secondary Preventive Services

Research is being intensified on a broad front to find preventive measures that will help people to avoid heart disease. While this type of fundamental research is being pursued, we can use other approaches to the control of heart disease by strengthening our secondary preventive services. These are directed at the earliest detection of asymptomatic heart disease and the detection of early disease, so that the progression of clinical symptoms may be halted and further damage to the cardiovascular system avoided or minimized.

It is in this field of secondary prevention that health departments can make significant contributions. It is not enough to offer postgraduate courses for physicians, to develop nutritional weight control programs for the obese, or to acquaint the public with the problems of heart disease by means of the techniques of health education. If we are to assault the chronic diseases with the same vigor and success with which we attacked the communicable diseases, we must employ epidemiological methods in the exploration of these new fields. With only a few minor exceptions, we don't know how much heart disease there is in our communities. We do not know what types of heart disease are prevalent; nor do we know what types can be benefited by early detection. For atherosclerosis and coronary disease, we have no accurate mass case-finding methods.

Where, then, do we start and what do we do? There are two approaches that can be used by any health department large enough to employ

full-time public health physicians and with courage enough to explore uncharted fields in public health.

Athero-coronary disease is the major contributor to death in the cardiovascular group. The various tests used to detect it early have not been evaluated either as to their relative efficiency or mass applicability. However, such studies can be undertaken by any large health department that can obtain random samples of the adult population at risk, and that has both the equipment needed for a battery of tests and the necessary professional and technical staff to perform and evaluate the tests.

This is a formidable task, but so was the early detection of syphilis and tuberculosis. It is better to spend the next few years in the determination of the reliability, validity, yield, cost, and acceptability of screening methods for coronary disease than to wait and muddle through with whatever might be available in the distant future.

Public demands for heart disease control programs are daily gaining momentum. It is inevitable that we will find new screening methods as we test the old, discard the inefficient, and develop those that single out most efficiently the potential and real, though obscure, cases.

Since early this year the New York State Health Department has had a small study group working on this approach to the problems of coronary disease and hypertension. We will launch our program on a group of several hundred key personnel in our State government in the age groups over 40, in which coronary disease and hypertension death rates are high.

We intend to seek out the most effective methods of detecting coronary insufficiency before occlusion or hypertension or cardiac hypertrophy occur. As soon as we achieve adequate information concerning mass screening methods and have accurate knowledge of the groups most at risk, we shall extend our activities to a full-scale community program, with the close cooperation of health departments, private practitioners, and medical schools.

Public Health Approach

Those of us over 40 years of age have a personal as well as a professional interest in

the public health approach to cardiovascular disease. Blumgart (1) found that among several hundred persons over 40 who died of non-cardiac causes and who had shown no evidence of heart disease, 40 percent exhibited on autopsy considerable hardening and narrowing of the coronary arteries. I urge initiation and pursuit of specific epidemiological studies.

The second approach to the problem of heart disease can best be made by county and city health departments because of their proximity to the sufferers from heart disease who will be needed for such studies. Specifically, I refer to the several hundred thousand chest X-ray films taken each year for the purpose of tuberculosis case finding. Rutstein, Williamson, and Moore (2), in their Boston study which was reported in November 1951, have clearly demonstrated that it is possible by means of 70-mm. photofluorographic film to identify in the general population a significant number of persons who have previously unknown heart disease. To be sure, skilled cardiologists must reread the films. When this is done, three times as many abnormal hearts are found as when less-skilled film readers review the films. In addition, persons with abnormal hearts must be referred to clinicians and followed up by their private physicians.

Here is an extraordinary opportunity for the health officer to initiate cooperative activity of major importance between the health department and the medical profession. Great benefits will accrue to thousands of cardiac patients in terms of productivity, personal happiness, and prolonged life.

Rutstein and his colleagues (2) point out that all newly discovered cases of rheumatic fever were benefited, because they learned to avoid further exposure to streptococcal infection and subacute bacterial endocarditis after operation or tooth extraction. In addition, many heart patients were more amenable to the techniques of vocational rehabilitation. Similarly, newly discovered cases of hypertensive or arteriosclerotic heart disease with auricular fibrillation, angina pectoris, and marked obesity certainly could be benefited by prompt referral to medical care. There was also a miscellaneous group of cases—congenital syphil-

itic, thyrotoxic heart disease, and pericardial tumors—that were greatly improved by medical or surgical therapy.

Private Physician Benefited

Such case finding through mass surveys of well people will enable the private physician to see patients in the asymptomatic stages of their disease, when therapy has its greatest effectiveness. Moreover, public health activities in this field will supplement the practicing physician's case finding in his office. This is just one example of the kind of epidemiological work local health departments can conduct successfully.

Priority for Chronic Diseases

The impersonal numbers on the mortality tables cannot convey the tragic stories of human suffering and family disruption that follow in the wake of crippling attacks of heart disease. The magnitude of the problem gives high priority, on the agenda of the health officer, to cardiovascular disease study and control.

Similar epidemiological studies should be undertaken in the field of cancer. Such an enterprise will also demand the active cooperation of the practicing physician and the public health worker.

In attempting to conquer heart disease, cancer, and the other chronic diseases, it is essential that we enlarge the scope of coverage and the number of services which the medical profession and public health agencies can provide. In New York State, we have been for years keenly aware of the necessity of providing medical care for the indigent, and we can boast of the best medical care program for welfare recipients of any State in the Nation.

To make medical care for the indigent even more certain and universal, the New York State departments of welfare and health recently took a significant step forward in cooperative governmental endeavor. The State health department established the new position of assistant commissioner of health (for welfare). One of our key public health administrators was assigned to the Department of Social Welfare to develop and evaluate the

medical care program for recipients of public assistance. It is a unique arrangement in government. The new assistant commissioner is responsible to the commissioner of health for professional guidance and has full access to all the information and facilities of the State health department; administratively, he is responsible to the commissioner of social welfare in whose department his office is located.

These medical care programs for more than 3 million persons are locally administered and use the facilities, services, and personnel of both the public and voluntary medical agencies and institutions. Through local hospitals and dispensaries, approximately 850,000 persons receive medical care annually at a cost of \$106,000,000. Through local public welfare agencies, 250,000 needy sick persons are cared for at home and in doctors' offices at a yearly expenditure of more than \$6,000,000 in public assistance funds. We have an unequalled opportunity to integrate preventive services of health departments into curative services of welfare departments.

Through this interdepartmental cooperation, private physicians, public health and welfare officials, nurses, social workers, rehabilitation specialists, and many others will be working together in an integrated, sustained effort to restore to health and to useful community roles thousands of the diseased and disabled whose impairments have reduced them to economic and social dependency.

It is by means of such cooperative enterprise that we may make a beginning toward the achievement of our high goals. By such realistic teamwork we can conserve efforts, personnel, and funds, and we can measure and surmount the barriers which daily we encounter in our work.

Philosophical Merger Necessary

Public health agencies cannot do these gigantic tasks alone. It will require the cooperative efforts of the whole of society. Particularly will it require a philosophical merger of the policies of medical societies and public health agencies. Clinical medicine is becoming increasingly aware of its role as a social instrument, and public health practice is perceiving

more keenly the problems of the individual in his relation to the family and the community in which he lives and works. But we need a closer working arrangement before we can be effective in controlling heart disease and cancer.

Lest it be feared that by working closely with official public health agencies the medical profession will suffer a loss of freedom, it should be said that complete freedom is not necessarily the natural state of human beings in a crowded society. It is something that can be obtained only within natural limits by continually clearing away obstructions. In seeking freedom in a medical field or profession, it is not enough to say that we want special privilege and the license to do what we like. We must first answer the question, "Freedom for what?"

What we seek is freedom to serve. To be sure, the practicing physician should have every freedom in the exercise of his judgment in the care of his patients. Much of the value of medicine rests on the willingness of sincere physicians to spend unlimited time and effort because they feel responsible for the patient's life and happiness. When this personal feeling is artificial or absent, the work of physicians descends to a low level of effectiveness.

We ought to strive for and insist upon two things that can be coexistent—professional freedom and professional responsibility. Properly viewed, the work of the whole medical profession, which includes public health, is not done in our private interests but in the interest of the community.

With this broad view of professional freedom and responsibility, the private physician and the public health physician can serve the individual and the community to best advantage by working together. They must not be driven by a desire for personal gain alone, but by a

willingness to serve the common good. The breadth of this concept emphasizes the scope of action in which all members of the medical profession should participate. Without such a wide horizon, we shall become ingrown and isolated from the dynamic trends of social evolution.

If we are to achieve this common objective of professional cooperation, it is vital that the medical profession, which holds a key position in the social order, close its ranks and that public health and private physicians contribute their full quota to the common effort. We must be prepared, while retaining the best of our traditions, to adjust our efforts to the changing conditions in society.

Medicine changes with time and place, and we must keep abreast of these changes. This will require mutual understanding and faith and trust. The result will be a fuller appreciation on the part of the public health worker of the problems of the general practitioner, plus enlightened awareness on the part of the clinical physician of the responsibilities and special attributes of the public health physician.

We stand at the crossroads. We must take new direction and answer the medical and social questions posed by the chronic diseases as we continue to carry the burdens of our regular work. With courage and with faith in the creative mind of man, we shall succeed.

Ideas

Ideas need not be unique to be universal. Ideas need not be new to be unique. They need not be dramatic. But they must be useful. Let the readership of Public Health Reports be your sounding board.

—THE EDITORS

Recruiting Aid

VIRGINIA. A practical aid to recruitment of public health nurses has been worked out between the Virginia State Department of Health and the State Highway Department. New employees who do not own cars and are unable to purchase them immediately may have State cars assigned to them for official duty for 6 months. The health department reimburses the highway department on a basis of 4 cents per mile. This provision has proved to be a real asset, since the majority of young graduate nurses are obviously unable or unwilling to take on the financing of a car before they have had a chance to settle down to a new job. Postponing the employment of a much needed nurse because a car is not available has been reduced to a minimum through the plan.

Moreover, if an employee's personal car is out of use because of repair work, a State car may be obtained to cover the period of expected need, a provision which has helped local health departments.

Waiting-Room Reading

DELAWARE. The Delaware Water Pollution Control Commission not only places information in the hands of the people—but also gets them to look at it. Informational literature is sent to doctors, dentists, barber shops, and beauty parlors as waiting-room reading material. Almost

everyone at some time or other finds it necessary to kill a little time in one of these establishments. The dog-eared nature of the available literature is tell-tale evidence of the fact that it is perused intensively.

Water Fluoridation Kits

NEW YORK. Many health officers have shown a keen interest in effective ways and means of informing their communities about water fluoridation. The New York State Health Department meets this need with a kit of useful material which includes a pamphlet on fluoridation, suggested news releases, a list of communities which have adopted fluoridation, and a list of equipment and supplies needed by a community in fluoridating its water supplies.

The packet, representing the combined efforts of the health department's bureau of dental health and office of public education, is being distributed to New York State health officers, women's groups, and other interested organizations.

Clinic for Dogs

NEW JERSEY. A clinic to treat and study cancer in dogs has been set up by the Bureau of Biological Research at Rutgers University. Dogs get both benign and malignant tumors, some of which resemble tumors in human beings. The Cancer Clinic for Dogs, where dogs are the patients, may turn up knowledge helpful in treating cancer in man.

All sick dogs are treated free, but the clinic accepts voluntary contributions from dog owners who are interested in expanding research on this particular victim of cancer. Financial assistance was contributed by the Public Health Service, and the Veterinary Medical Association of New Jersey endorsed the organizing of the unique research center.

As soon as the facilities are available, ill dogs will be accepted from other States, but for the time being the clinic accepts its canine patients

for treatment only on reference of veterinarians in New Jersey, who have been asked to cooperate in sending suspected or active cases of cancer to the research laboratory for study. One function of the Cancer Clinic for Dogs is its diagnostic assistance to veterinarians—the electroencephalograph it uses will measure electrical waves in the brain, an advanced method of diagnosing damage which few veterinarians could afford.

Dial Once

CLEVELAND, OHIO. One telephone call will locate a health film in Cleveland now—no longer will it be necessary to make four or five calls.

By placing a telephone call to any one of four well-publicized information points, an inquirer can find out whether or not any film on a health topic is available in Cleveland, and where. He can find out other items of interest too: the film's running time; the rental charge if the film is not available for free use; the age level best suited for viewing the film; or the name and address of the producer should he want to purchase the film. The bureau of health education of the Cleveland Division of Health put the new system into effect at the request of the Cleveland Health Council.

Instrument Holder

BROOKLYN, N. Y. Laboratories can easily make a rack to hold inoculating needles, glass rods, pencils, or small laboratory instruments.

The laboratory of the Public Health Service Hospital at Manhattan Beach constructed such a holder by stretching a wire spring across a white enamel metal back.

The holder looks like the familiar kitchen knife holder. It is neat, easy to clean, easy to see, easy to use—especially if conveniently located on a wall near the workbench.

Time is saved by not having to search through drawers for instruments.

Age Aspects of Environmental And Occupational Cancers

By W. C. HUEPER, M.D.

For many years, age factors have played an important and widely accepted role in theories of cancerigenesis (9). Curiously enough the concepts advanced in this matter are related to both ends of the age range. Some investigators adhere to Cohnheim's theory that cancers originate from misplaced embryonic cells. Others are followers of the senescence theory of carcinogenesis and believe that cancerigenesis is in some way closely connected with the physiological changes associated with advancing age. The outlook for achieving a reasonable control of cancer by preventive measures would be dark indeed if either theory proved correct or applicable to all or most types of cancers. It is most unlikely that effective measures can be found to prevent the production of the hypothetical ubiquitous embryonic cell misplacements during fetal life. Likewise, there is little prospect of modifying physiological aging processes in such a way that they would lose their alleged carcinogenic properties.

Fortunately, numerous observations made during the last two decades in the fields of environmental and experimental carcinogenesis tend to minimize greatly the significance of primary age influences in the development of

malignant tumors and to demonstrate the actual or potential part that exogenous agents assume in bringing about cancerous reactions through a direct or indirect action mechanism (7, 9). A revaluation and redefinition of the role of age in the problem of cancer and especially in its environmental aspects appears to be timely and needed.

Relationship of Age to Cancer

Although the majority of cancer deaths in the United States and Europe involve individuals between the ages of 30 and 60 years, there is a progressive and steep rise in cancer incidence, if the incidence rate of cancer is expressed in terms of cancers per 10,000 individuals of identical age (1, 22). It is remarkable, however, that the increase in cancer incidence with advancing age is more marked for carcinomas than for sarcomas. Some investigators (3) have attempted to reconcile this discrepancy in the age distribution of carcinomas and sarcomas by the hypothesis that connective tissues age faster than epithelial ones. Such a supposition lacks factual support. Observations on experimental and environmental cancerigenesis clearly demonstrate that the histological type of cancer depends upon the tissues to which the cancerigen is applied, or into which it is implanted, or in which it is retained and stored, or for which it possesses a special affinity.

When considering the relationship of age to cancer, there remains the well-established fact that cancers originating from many tissues occur at all ages from the prenatal to the senescence period. Indeed, cancer is the second or

Dr. Hueper is chief of the carcinogenic studies section, cancer control branch, National Cancer Institute, National Institutes of Health, Public Health Service. He presented this paper before the Second International Gerontological Congress at St. Louis, Mo., September 1951.

third most frequent cause of death even during the first three decades of life, if deaths from accidents are excluded. Thus among the fatal diseases, cancer ranks high at any age period.

Age Distribution

Additional inconsistencies in the concept of direct age relationships to cancer become apparent when the modal age at death from cancer of different organs is studied (22). According to Holtz, incidence maximums for cancers of the testes, kidney, and suprarenal are found at an age range of 0 to 4 years, for tumors of the bones at 15 to 25 years, for cancers of the testes at 30 to 35 years, for cancers of the brain at 40 to 45 years, for cancers of the female sex organs at 50 to 55 years, for cancer of the skin and abdominal organs at 60 to 65 years, and for cancers of the prostate at more than 70 years. Apart from the fact that certain special types of cancers occur almost exclusively during infancy and childhood (Wilms' tumor of kidney, retinoblastoma, botryoid sarcoma of vagina), cancers of some organs have several age peaks of frequency (cancers of the testes, brain, and blood-forming organs).

While melanomas occur at all ages without any special prominence in any particular decade, except that they are rare in young children, they display a different and unique relationship to age inasmuch as there is a precipitous rise in the capacity of melanomas to metastasize after puberty despite their histological similarity to the usual nonmetastasizing juvenile melanoma (19).

Regional, Sex, and Race Distribution

There are marked variations in the total cancer incidence as well as in the relative incidence of some organ cancers (skin, lung, mouth, stomach, liver) in the populations of different parts of the world and in different regions of the United States. While some such differences can readily be explained by the considerable variations in the average life span in different countries or by certain racial characteristics, or both, they do not reflect primary biological differences related to age. For instance, there are good reasons to believe that the differences in

susceptibility to, and incidence of, cancer of the skin between fair-complexioned and dark-complexioned people are caused by differences in the functional and anatomical qualities of the skin, and that they are not attributable to fundamental variations in some age attributes of the skin of population groups with varying degrees of pigmentation.

Likewise, it is not conceivable that the marked differences in sex distribution of several organ cancers (skin, larynx, lung, bladder, esophagus, lip, tongue, mouth, tonsil, pharynx) represent sex-conditioned variations in the distribution and number of embryonic cell rests or in the time of onset and speed of aging processes of the tissues from which these cancers originate.

The incidence ratio for males and females for cancer of the skin is 4:1, for cancer of the lung from 2:1 to 20:1, for cancer of the larynx 10:1, for cancer of the bladder 5:1, for cancer of the esophagus 10:1. The dilemma in which the protagonists of an age theory of cancer find themselves in this respect is increased by the fact that these ratios are not fixed. They vary in different countries with the changes in environmental conditions, such as the trend toward an equalization or reversal of the sex ratio of cancer of the mouth in India and the Philippines where the chewing of betel nut quids is habitual.

Embryonic Cell Rests and Cancer

The difficulties in attempting to connect age with cancer are accentuated if age concepts are applied to a specific theory, such as Cohnheim's theory. Although some exceptional cancers (Wilms' tumor, and testicular and ovarian teratocarcinomas), usually appearing during the first two to three decades, may be derived from embryonic tissue misplacements, this evidence furnishes little support for the claim that most tumors observed during early life originate from embryonic cell rests (16) or are the result of developmental mechanical disturbances (21), because the typical cancers of adults produced by exposure to exogenous agents are extremely rare in children.

It is a well-established fact that numerous exogenous chemicals introduced into the body

of a pregnant woman can penetrate the placental barrier and act upon the fetus. Theoretically, thus, it is conceivable that a fetus may become exposed to carcinogenic agents entering the fetal circulation from the maternal side (9) and causing cancers during the prenatal or postnatal period. The successful experimental induction of pulmonary tumors in the offspring of mice by a transplacental exposure to urethane administered to the pregnant mouse (11) supports this concept.

Senescence and Cancer

The main argument advanced in support of the senescence theory of cancerigenesis is the statistical relationship between advancing age and rise of cancer incidence. The disturbing existence of different age ranges for the peak incidence of cancers of various organs is explained by the proponents of the senescence theory through the introduction of the concept of heterochronic or disharmonic aging of the various organs, while the appearance of cancers during a comparatively early period of life in which senescent processes are not prominent is regarded as the result of local abnormal precocious tissue senescence occurring on the basis of a congenital constitutional predisposition.

Additional support for the senescence theory is sought by claiming that the length of the latent period of cancers induced by exogenous agents in experimental animals bears a direct relationship to their normal life span, that is, the rate of tissue senescence of a particular species controls the speed of cancer development. Wells contended that from one-fifth to one-tenth of the life cycle of an organism ordinarily is required to produce a malignant tumor.

Since most of the cancers occur in individuals who have entered the "senescent" phase of life, it is only natural that in many instances senescent changes are found in coexistence with cancerous reactions. However, many of these "senescent" changes are not physiological but the result of prolonged exposure to exogenous agents, some of which have cancerigenic properties, such as solar radiation, tar, pitch, petroleum derivatives, arsenicals, and ionizing radiation. Spontaneous as well as exogenously induced cancers in man and animals not infre-

quently develop in a tissue that does not show any so-called "senescent" changes. Pulmonary tumors in mice and aromatic amine cancers in man and dogs illustrate this fact. Finally, cancers are infrequent in certain organs (salpinx, urethra, blood vessels, kidney, testis, heart, bones) at an age period when the atrophying and fibrosing manifestations of advancing age are present.

Latent Period of Cancer

Additional and important evidence against the validity of the senescence theory of cancer is furnished by observations on the latent period of occupational, environmental, and experimental cancers. Willis (22) noted that "We now know that cancer is mainly a disease of the elderly, not because senile tissues are 'predisposed' to cancer, as was once supposed, but because of the usually long latent periods elapsing between the application of carcinogenic stimuli and the development of tumors. Occupational and experimental tumors show that these periods often occupy large fractions of the life spans of the affected animals." The validity of this statement is supported by the data in table 1.

The observations from the field of environmental and occupational cancerigenesis not only

Table 1. Latent periods of occupational cancers

demonstrate that the basic cancerization process antedates often by many years the time at which the cancer becomes manifest, but they also show that the age at onset of exposure and the intensity of contact with the carcinogenic agent determine the manifestation age.

When children from 4 to 10 years old entered the profession of sweeps in England during the early part of the last century, chimney sweeps developed scrotal cancer at an average age of 30 to 40 years (5). After this practice was discouraged by law and sweeps did not start in the trade before the age of 16, the average age at which scrotal cancer in sweeps was observed rose to from 45 to 50 years at the end of the nineteenth century (4). With the subsequent introduction of improved hygienic conditions and technical procedures reducing the intensity of exposure to soot, the average age of sweeps with scrotal cancer increased to 61.9 years by 1935 (8). The evidence clearly shows that the progressive and considerable increase in the average age of sweeps with scrotal cancer was directly dependent upon the later onset of exposure and on a reduction in the intensity of exposure (12). While sweeps still have a higher liability to scrotal cancer than the general population, the average manifestation age of scrotal cancer in sweeps is now identical with that of scrotal cancers of unknown etiology (table 2).

¹ Butlin (4).

² Henry (8).

A similar effect of the age at onset and of the intensity and the duration of exposure to an environmental carcinogenic agent upon the average manifestation age of the resulting cancers is evident in arsenical cancers of the skin. While the average age of skin cancer patients

is about 60 years (14), approximately one-third of 115 medicinal arsenical cancers were seen in patients less than 40 years old, and more than 60 percent were not older than 50 years (13). Likewise, the average age of persons with occupational X-ray cancer of the skin is in the age group 41-66 years (9). Occupational cancer of the bladder of chemical or parasitic origin also is characterized by an age incidence which favors the younger age groups below 50 years of age (aromatic amine cancer: 52.8 percent of all cases in individuals less than 50 years old; schistosomiasis cancer: mainly in individuals 30 to 40 years old), contrasted with an age distribution of more than 50 years for 65 percent of all cryptogenetic bladder cancers.

The evidence presented in table 3 shows a shift into younger age groups for skin cancers caused by arsenicals, pitch, paraffin oil, shale oil, and X-radiation, for cancer of the lung induced by tar and ionizing radiation, and for cancers of the bladder produced by betanaphthylamine and benzidine.

Observations made in experimental carcinogenesis also demonstrate beyond any doubt that the length of the latent period and, thereby, the manifestation age is not dependent upon any senescent changes or on the average life span of a species, but on the intensity of exposure to a carcinogen and to the specific potency of a carcinogen for the particular species. Numerous investigators have shown that young animals react to carcinogenic hydrocarbons as readily as, if not more readily than, adult animals (2, 17, 20, 23):

Rusch and Baumann¹ noted that the latent period of ultraviolet-ray cancer in mice was 3.5 months if the daily period of exposure was 60 minutes. It was increased to 9 months when the exposure period was reduced to 10 minutes. Rabbits and guinea pigs, on the other hand, have proved refractory to the carcinogenic action of ultraviolet rays. The latent period of bladder cancer in dogs fed betanaphthylamine daily is from 18 to 24 months, while it rises to 5 years if the feeding of the chemical is discontinued after 6 months. Fieser and co-workers (6) found that the average latent period of skin cancer in mice varied with different carcinogenic hydrocarbons. It was 2.5 months

for methylcholanthrene, 3.5 months for 3,4 benzpyrene, and 7 months for 1,2,5,6 dibenzanthracene when these chemicals were tested under standardized conditions. Hueper observed that hairless rats, which have a normal life span of about 360 days and a markedly keratotic skin, were definitely less susceptible to the carcinogenic action of ultraviolet rays than normal albino rats having an average life span of 555 days, while both strains were refractory to methylcholanthrene in a benzolic solution applied to the skin.

Additional evidence militating against the fundamental importance of age factors in the production of many human cancers is provided by observations on the epidemiology of penile cancer. The large-scale Jewish experience with circumcision on the eighth day of life indicates this procedure affords complete protection against a subsequent development of penile cancer, and the studies of Schrek and Lenowitz (15) on circumcised American white persons and Negroes suggest that circumcision performed during the first 6 years has a similar protective effect. Circumcision at a later age

(6 to 35 years), on the other hand, does not result in any significant difference in the incidence of penile cancer between circumcised and noncircumcised individuals. Since the interval between circumcision and the appearance of penile cancer ranges from 8 to 40 years with an average interval of 23 years (10), it is evident that the specific cancerigenic exposure in penile cancer apparently takes place during the first 10 to 15 years of life.

The high death rate of cancer of the lung among miners of radioactive ores, which stands at some 70 percent of all deaths for the Schneeberg miners and at some 40 percent for the Joachimsthal miners, cannot be attributed to the existence of a "preferential" type of aging among these population groups. The progressive rise in the incidence of pitch warts and cancers among English pitch workers from 17 percent of the workers after 1 to 5 years of exposure to 100 percent after more than 40 years of exposure (18) provides an additional illustration of the lack of importance of senescent changes in the causation of occupational cancers.

Conclusions

Numerous observations made in connection with cancers in general as well as especially with environmental and occupational cancers indicate that neither embryonic cell rests nor senescing tissues play an important or essential role in the development of malignant neoplasms.

Against the existence of causal and direct age relationships to cancerogenesis the following facts may be cited:

1. Only carcinomas but not sarcomas exhibit an incidence rate that significantly increases with age.

2. Cancers of different organs have widely varying age peaks covering the entire life span. Several organ cancers have two or even three distinct age peaks.

3. The distribution of cancers by sex, race, and regions displays a pattern that cannot be reconciled with a uniformly operating age factor.

4. The well-established occurrence of occupational cancers during childhood, the experimental transplacental induction of lung tumors in mice, and the consistent development of occupational and experimental cancers by exogenous carcinogens at predeterminable sites and after predictable periods of exposure strongly indicate that embryonic cell rests account for only the exceptional cancer and that senescent tissue changes are unimportant.

5. Many of the so-called senescent changes in tissues allegedly providing the prepared soil for cancer represent the result of prolonged exposures to specific environmental or occupational cancerigenic factors.

6. Numerous observations on environmental, occupational, and experimental cancerogenesis prove that a long latent or preparatory period precedes the appearance of cancers following an effective exposure to a carcinogenic agent. It is mainly for this reason that the majority of such cancers are observed during the later part of life.

7. The validity of this concept is supported by the fact that the length of the latent period is dependent upon the intensity and duration of exposure to a carcinogenic agent and to its relative carcinogenic potency.

8. The manifestation age of environmental

and occupational cancers is directly related to the age at onset of the cancerigenic exposure.

9. The excessive frequency of cancers of certain organs among members of special professions and occupations also suggests that factors other than physiological aging are responsible for the causation of these neoplasms.

The evidence presented supports the view that cancer development in organs or tissues having early, frequent, and prolonged contact with exogenous agents is in most instances not directly or indirectly related to age factors. It appears possible, however, that organ cancers, which may be the result of functional or hormonal disturbances, may, in part, be dependent in their genesis on the action of age factors, because changes in the internal environment associated with and resulting from organic functional impairments and imbalances occur with advancing age.

Dr. Knutson Appointed Chief Dental Officer

Dr. John W. Knutson was named the new chief dental officer of the Public Health Service by Surgeon General Leonard A. Scheele early in June. Chief of the Division of Dental Public Health until then, Dr. Knutson succeeded Dr. Bruce D. Forsyth on the latter's conclusion of a 4-year tour of duty as chief dental officer.

A member of the commissioned corps of the Public Health Service since 1934, Dr. Forsyth has been assigned to Federal Security Agency Region I in Boston as regional dental officer for the Public Health Service. In his new capacity, Dr. Forsyth will act as dental consultant for the New England area.

Also a commissioned officer since 1934, Dr. Knutson joined the Public Health Service in 1931. He served as dental clinician at Public Health Service hospitals in Chicago, and Norfolk, Va., during his early career. From 1938 to 1940; Dr. Knutson was assigned to the National Institutes of Health, Public Health Service, to conduct research in dental caries. For the next 4 years, he conducted demonstration studies and laboratory research in dental health at the Minnesota State Department of Health. He became chief of the dental section, State Relations Division of the Bureau of State Services, in 1944, where he acted as dental consultant to State health authorities until his appointment as chief of the Division of Dental Public Health in 1949.

Dr. Knutson's predecessor, Dr. Forsyth, served as chief dental officer at various Public Health Service posts between 1934 and 1948, including the U. S. Reformatory at El Reno, Okla., and Public Health Service hospitals and clinics in New York, Fort Worth, Tex., and Washington, D. C.

Voluntary Reporting of Venereal Diseases

—In Contacts Previously Reported Not Infected—

By BENSON H. SKLAR, M.Sc.P.H., LEONARD M. SCHUMAN, M.D., M.Sc.,
and NORMAN J. ROSE, M.D., M.P.H.

A central registry of venereal disease cases and contacts was established in 1944 in the Illinois Department of Public Health to eliminate duplication of reporting and to provide a screening device for laboratory positives, field assignments, and correspondence. All information pertinent to the case or contact is coded on punch cards and filed alphabetically with this registry. A duplicate set of cards containing morbidity data is kept for background.

Records in this central registry show that some individuals are reported repeatedly for clinical progression in the course of syphilis, as new infections of syphilis, and as new infections of gonorrhea. This information, when filed in a central registry, provides an instrument which lends itself to analysis of administrative procedures. It is also proposed to use this method to determine whether contacts to primary or secondary syphilis cases who had been found upon initial examination to be not infected would, because of their presumed promiscuity, be reported subsequently as new cases of venereal disease. With the results of such a study in mind, efforts might be directed toward subsequent programs to follow up these contacts to primary and secondary syphilis

cases, in an effort to find new cases of venereal disease.

Such a study suggests two avenues of approach: (a) a check of the central registry to determine voluntary reporting of such contacts as cases by private physicians or clinics, and (b) an actual field demonstration on contacts found previously noninfected. This paper is based upon the first method.

Method

Since the establishment of an assignment and report form in 1944, all information on each case followed as a field assignment is recorded on a punch card, making possible the tabulation in the central registry of results and other pertinent data on venereal disease investigations. For this study, all reports of contact investigations in which information was available on contacts to primary and secondary syphilis cases were sorted from the file. The reports which indicated that the contact was not infected when examined were used in this study. A list of such contacts to primary and secondary syphilis cases who were found upon investigation to be not infected was established for each year from 1946 through 1950. Records on these contacts, giving pertinent information, such as age, sex, color, and county of residence, were filed alphabetically. The records were then checked against the central registry files for any diagnostic and treatment data available there. In some cases, central registry information represented data obtained

The authors are with the Illinois Department of Public Health: Mr. Sklar is executive officer of the office of procedures and reports, division of preventive medicine; Dr. Schuman, deputy director of that division; and Dr. Rose, chief of the bureau of epidemiology.

prior to completion of the original investigation; in most cases, after the completion of the original investigation.

Results

Tables 1 and 2 indicate the results of a check of contact listings with the central registry. This screening was made during May 1951, and represents a 5-year check of contacts originally reported not infected, to determine if they eventually were reported by private physicians or clinics as cases of venereal disease. The central registry was used to screen this list of contacts for diagnostic and treatment data. The records of 1,935 contacts found not infected on initial investigation yielded morbidity information on 266, or 13.7 percent; 198, or 10.2 percent, were found infected sometime after the conclusion of the initial examination; and 68, or 3.5 percent, were found to have been infected with a venereal disease prior to the date of investigation. Of the 198 contacts found infected with a venereal disease in the ensuing 5 years of this study, 90, or 45.5 percent, were reported as cases of syphilis, while 108, or 54.5 percent, were reported subsequently as cases of gonorrhea. The 90 syphilis cases represent 4.6 percent of the noninfected contacts subsequently reported, with 53 of these, 59 percent, in the primary or secondary stage, while the 108 gonorrhea cases represent 5.6 percent of the orig-

inal screened contacts. A decreasing trend in the ratio of reporting new cases of venereal disease to the numbers screened each year is noted in this study. In 1946, 12.4 percent of these contacts were subsequently reported as cases, while in 1950 only 5.2 percent were found to be infected with a venereal disease.

Table 1 shows that 68 of these contacts were reported as cases of venereal disease sometime before their investigation as contacts. This case information relating to such contacts was brought to light by correspondence, recent morbidity reports, and by other means. Of the 68 contacts reported as infected before the initiation of such investigation, 29, or 42.6 percent, of the infections were syphilitic, while 39, or 57.4 percent, were gonorrheal.

Table 3 summarizes the results of such a screening procedure. The highest percentage of venereal disease among contacts was found to have been contracted during the first year after the examination at which the contact had been reported to be not infected. A decreasing trend in these percentages is apparent for these noninfected contacts for the next 4 years. The majority of the first-year-interval reports are for primary or secondary syphilis.

Discussion

This study indicates that of the 1,935 contacts checked, 90, or 4.6 percent, were subsequently re-

ported as cases of syphilis. Of the syphilis cases found, 59 percent were diagnosed as being in the primary and secondary stages. It is interesting to note that most of these infectious cases were diagnosed during the first year after they were examined as contacts and found to be not infected. In order to determine whether any of these infectious cases were missed during their initial investigation and examination as contacts, a sample survey of similar assignments indicated that the notation "examined not infected" was entered on these investigation reports at varying lengths of time after the exposure date—70 percent were followed for 90 or more days; 20 percent, 60 to 90 days; and 10 percent less than 60 days. If this sample is acceptable as representative of the whole experience, the number of contacts subsequently reported as infected, and probably by the same initial exposure, would be insignificant. It must be remembered that 10 percent of the cases were followed less than 60 days—an interval well above the average incubation period for the disease. This, however, does not minimize the need for adequate follow-up of such contacts.

The percent of cases (4.6) subsequently reported among contacts initially found noninfected is deemed to be significant in view of the fact that these were spontaneously reported without added follow-up incentive. Compared to the rate of voluntary reporting of new cases among the population at large, this group of contacts, who have been at risk and may con-

tinue to be at risk because of established promiscuity, constitutes a reservoir of new cases toward which case-finding efforts might be directed. The statistics which in recent years have pointed out the magnitude of undiagnosed, and hence unreported, cases tempt the inference that many more new cases could be elicited by re-examining the "noninfected-contact" reservoir, for in it there may well be many subsequent exposures. Certainly, serologic surveys are not selective of such groups but are applied to the general adult population at great cost and extremely low yields of early infectious cases.

The decreasing trend in the ratio of new cases of venereal disease reported to the numbers screened each year is shown in table 2. With prolongation of time for presumed promiscuity, when all other factors are constant, increased cumulative exposure, and hence increased infection and subsequent higher incidence of voluntary reporting are expected. Certain factors which qualify these assumptions are: (a) the increased incidence of venereal disease during war periods, and (b) the present decreasing incidence of reported new infections of venereal disease. In this 5-year study, representing a period of national emergency after the termination of World War II, the reported infection rate of syphilis rose and then declined precipitously. During the peak years of infectivity, increased promiscuity probably yielded increased morbidity because of increased exposure

Table 3. Noninfected contacts later reported as venereal disease cases by interval of time between contact investigation and report as a case

Interval between contact investigation and report of contact as a case (years)	Total contacts for each period	Total venereal disease		Syphilis						Gonorrhea	
				Total		Primary and secondary		Other			
		Number	Per-cent	Number	Per-cent	Number	Per-cent	Number	Per-cent	Number	Per-cent

risk, while during the years of decreasing infectivity, promiscuity may not have yielded similar increased morbidity because of the lessening of this risk.

The entire yield of the investigation of contacts to infectious cases of syphilis who were found not infected on their initial examinations will be determined not only from spontaneous reporting of such contacts as new cases of venereal disease, but also from a careful field investigation of such contacts who were not spontaneously reported. It can, however, be noted from results of this study that a follow-up of a presumed promiscuous population may be worthy of administrative trial, inasmuch as cases reported voluntarily represent only those who seek medical care from physicians who may not report them to a health department. Such an approach is now in operation on a demonstration and research basis and will be reported later.

Summary and Conclusions

1. Of 1,935 contacts reported after investigation as noninfected, 266, or 13.7 percent, were subsequently reported as having become infected with syphilis or gonorrhea. Of these,

198, or 10.2 percent, of the contacts initially investigated were found infected sometime after the conclusion of the initial investigation.

2. Syphilis cases reported in this group totaled 90, or 4.6 percent, of all noninfected contacts.

3. Early infectious (primary and secondary) syphilis totaled 53 cases, or 58.9 percent of all cases of syphilis subsequently reported.

4. The majority of all venereal disease cases subsequently reported among such "noninfected" contacts were reported within 1 year after the initial investigation.

5. The spontaneity of this reporting is emphasized and inferences drawn as to yield after re-examination of the noninfected-contact reservoir.

6. Voluntary reporting of venereal diseases by reporting agencies to the venereal disease central registry in the Illinois Department of Public Health has been utilized in this study to pinpoint administratively the need for further control measures in the follow-up of contacts to primary and secondary cases of syphilis, who, upon their initial examination and investigation, were found to be not infected with a venereal disease.

Dietary Standards in the United States

By L. A. MAYNARD, Ph.D.

The dietary standards in general use by Government agencies and food and nutrition scientists throughout the United States are the recommended dietary allowances formulated by the Food and Nutrition Board of the National Research Council. These dietary allowances, revised in October 1948, are presented in the accompanying table (1).

Normal Food Supply Situations

The dietary allowances specify levels which the Food and Nutrition Board recommends as "normally desirable goals or objectives" in dietary practice. The allowances for the different nutrients are generally higher than those found in other promulgated standards because they are intended to represent not merely average requirements, but "levels enough higher to cover substantially all of the individual variations in the requirements of normal people." Many individuals would thus receive intakes above their needs, but there seems to be no way of identifying persons whose requirements are

markedly above the average, and the board has no evidence that any individual would be harmed by consuming the full nutrient allowances specified.

All of the allowances are intended to represent intakes actually consumed. As is to be expected in the present state of our knowledge, the data represent some compromises of the views of those qualified to express an opinion with respect to a given nutrient. Nevertheless, the table as a whole has won widespread acceptance. None of the values, however, are considered final. A committee of the board is constantly examining new data as they appear and re-evaluating the old, with the objective of making needed modifications. It is also reviewing previously and currently published studies to provide data for nutrients not now included in the table. The data and viewpoints set forth in the reports of the United Kingdom and of Canada, published since the last revision of the recommended dietary allowances, are among the studies being given consideration by the committee.

The experimental bases and other considerations which led to the formulation of the present recommended dietary allowances are set forth in considerable detail by the National Research Council (1). A few explanatory statements regarding certain values are given here.

Calories

In contrast to the situation with respect to nutrients, there are definite reasons why unneeded intakes of calories should be avoided by adults. It is simple to state that each person

Dr. Maynard is chairman of the Food and Nutrition Board, National Research Council, and director of the School of Nutrition at Cornell University, Ithaca, N. Y. This paper is based on material presented before the scientific session of the Combined Conference on Administrative and Scientific Aspects of Food in Civil Defense held in London, November 26 to December 3, 1951 (see Public Health Reports, July 1952, p. 607).

should consume enough calories, and no more, to maintain his ideal weight, but setting up a workable standard which will actually accomplish this for the individual is quite another

matter. Age, sex, body build, genetic make-up, physical activity, and climate all have an influence on the requirements.

The board's calorie allowances take into ac-

¹ Objectives toward which to aim in planning practical dietaries: The recommended allowances can be attained with a good variety of common foods which will also provide other minerals and vitamins for which requirements are less well known.

² Calorie allowances must be adjusted up or down to meet specific needs. The calorie values in the table are therefore not applicable to all individuals but rather represent group averages. The proper calorie allowance will maintain, over an extended period, body weight or rate of growth at the level most conducive to well-being.

³ The allowance depends on the relative amounts of vitamin A and carotene. The allowances of the table are based on the premise that approximately two-thirds of the vitamin A value of the average diet in this country is contributed by carotene and that carotene has half or less than half the value of vitamin A.

⁴ For adults (except pregnant and lactating women) receiving diets supplying 2,000 calories or less, such as reducing diets, the allowances of thiamine and niacin may be 1 mg. and 10 mg., respectively. The fact that figures are given for different calorie levels for thiamine and niacin does not imply that we can estimate the requirement of these factors within 500 calories, but they are added merely for simplicity of calculation. In the present revision, riboflavin allowances are based on body weight rather than calorie levels. Other members of the B complex also are

required, though no values can be given. Foods supplying adequate thiamine, riboflavin, and niacin will tend to supply sufficient amounts of the remaining B vitamins.

⁵ There is evidence that the male adult needs relatively little iron. The need will usually be provided for if the diet is satisfactory in other respects.

⁶ The need for supplemental vitamin D by vigorous adults leading a normal life seems to be minimum. For persons working at night and for nuns and others whose habits shield them from the sunlight, as well as for elderly persons, the ingestion of small amounts of vitamin D is desirable.

⁷ During the latter part of pregnancy the calorie allowance should increase to approximately 20 percent above the preceding level. The value of 2,400 calories represents the allowance for pregnant, sedentary women.

⁸ Allowances for children are based on the needs for the middle year in each group (as 2, 5, 8, etc.) and are for moderate activity and for average weight at the middle year of the age group.

⁹ Needs for infants increase from month to month with size and activity. The amounts given are for approximately 6 to 8 months. The dietary requirements for some of the nutrients such as protein and calcium are less if derived largely from human milk.

¹⁰ Amount required for 2.2 lb. (1 kg.) of body weight.

count sex differences and three categories of activity. The limitations involved in the use of these three categories are fully appreciated, but they cannot be overcome simply by adding more categories. The problem remains of so defining the categories selected as to permit the classification of a population accordingly. Although data are available for caloric expenditures in various types of work, the variable expenditures of individuals during nonworking hours or at tasks not covered by their regular work seem impossible to classify. In view of the variables not taken into account in the general recommendation, the board suggests that its caloric allowances be regarded as subject to modification of plus or minus 15 to 20 percent, according to conditions.

The need for more precise statements of caloric allowances is recognized, both because they are obviously dominant factors in the total food supply needed, and also because of the deleterious effects of an excess in the adult. Committees of the board are giving active consideration to the issues involved.

Calcium

The present adult allowance of calcium is 20 percent higher than the board's previous recommendation. Data obtained in the United States reveal a wide range in the calcium intake required by adults to maintain calcium equilibrium. For some, as little as 0.3 mg. daily appears to suffice, whereas at the other extreme some individuals, particularly elderly people, seem to require even more than 1 gm. daily. Although the average need is manifestly much less than 1 gm., the board felt that this figure was in keeping with the policy of setting the allowance high enough to meet the needs of all normal individuals. Recognition was also given to the evidence from experiments with rats that liberal intakes of calcium promote longevity.

Vitamin C

Although the board recognizes that the physical symptoms of scurvy can be prevented and even cured by much less vitamin C than specified in its allowances, the accumulating evidence regarding the variety of metabolic roles which the vitamin plays and the rapid depletion

of body stores during stress has indicated the desirability of maintaining a liberal supply in the blood and other tissues. The allowances have been placed accordingly.

Vitamin A Value

The content of vitamin A itself and of its precursor carotene together account for the vitamin A value of a dietary. The allowances given in the table for vitamin A are based on the premise that a unit of carotene has one-half the value of a unit of vitamin A per se and that in the average American diet two-thirds of the vitamin A value is supplied by carotene. The limitations and uncertainties of these bases, particularly in terms of specific foods and diets, are recognized.

Emergency Food Supply Situations

In answer to requests for suggestions which may aid State and local civil defense agencies in formulating plans for emergency feeding of uninjured civilians, the Committee on Dietary Allowances of the board has prepared a brief report. This report points out that it is unrealistic to expect to provide adequate diets or to designate specific nutritional requirements for any large population in emergencies following an atomic attack. It states that provision of foods to supply energy needs should suffice for the first few days of an emergency, especially if foods which supply protein and other nutrients, as well as calories, are selected.

According to the report, "drastic reduction of food intake for a few days, or even weeks, is tolerated reasonably well except by infants, by lactating women, by the sick and injured, and by those engaged in heavy physical work. This is particularly true if the calories that are available come largely from foods that furnish a variety of nutrients such as bread, potatoes, and milk, in contrast to foods such as sugar, syrups, and oils, which supply calories primarily." For periods of food shortage lasting longer than a few weeks, the report adds, special provision must be made for supplying foods not only for the more vulnerable groups, but also for pregnant women.

As the period of emergency is prolonged, the need for certain individual nutrients increases.

The report states: "If the emergency feeding must be continued for more than a few weeks, the problem of individual nutrients, as well as calories, assumes importance. Cognizance must be taken of needs for protein, thiamine, other B-complex vitamins, and ascorbic acid." Deficiencies of minerals and fat soluble vitamins are not likely to occur, however, unless food shortages persist over several months.

The report stresses the importance of nutritional appraisal of the population by trained survey teams as a part of any emergency program. Such an appraisal will detect any deleterious effects of the food allowance on health and will serve as a basis for further dietary planning.

In regard to use of foods on hand during an atomic explosion, the report points out that food present in closed containers is usually safe

if the outside of the container is washed. Food in open or broken containers exposed to radioactive materials should, however, be monitored before use. The report cautions against wasting food because of the possibility of contamination by atomic radiation.

The recommendations of this report, though much less detailed, are in general accord with those set forth by the Federal Civil Defense Administration (2).

Sanitary Storage and Collection of Refuse

16 mm., sound, color, 19 minutes, 1952.

Audience: Public health and sanitation personnel.

Available: Loan—Communicable Disease Center, Public Health Service, Box 185, Chamblee, Ga. Purchase—Castle Film Division, United World Films, 1445 Park Avenue, New York 29, N. Y.

Operations essential in the sanitary handling, storage, and collection of refuse from homes, restaurants, and business establishments are depicted by this film, produced by the Audio Visual Production Branch of the Communicable Disease Center, Public Health Service, in cooperation with the Public Health Service, Division of Sanitation.

The film is of particular interest to Public Health Service personnel—sanitary engineers, sanitarians, and health officers—and can be used by

them in working with municipal officials and local sanitation department employees. Refuse, the film points out, consists of both garbage and rubbish. Unless disposed of promptly, refuse furnishes harborage to rodents, flies, and mosquitoes. Local government agencies are encouraged to inform the individual property owner and restaurant operator how to store refuse properly to fit in with good community collection and disposal practices. Garbage may be separated from rubbish for disposal in grinders or to hog

farms, or the two may be combined for disposal in sanitary land fills or in modern predrying kiln process incinerators. In either case, the individual is responsible for sanitary storage of refuse on his own premises. He should wrap all garbage and place it in heavy metal, tight-lidded, conveniently located garbage cans.

The film illustrates several devices, such as cloth collection squares, to protect the citizen's cans and to make the loading of garbage into the truck easier. It emphasizes that planned collection routes, properly designed trucks, and courteous service by sanitation department employees pay off in health and efficiency.

Family Food Consumption Studies

By C. M. COONS, Ph.D.

It is a comfort to know that the Nation's supply of food appears to be sufficient in kind and amount, with some margins of safety, to meet the dietary requirements of its military and civilian populations. But it may be cause for concern and action to find that many families have poor diets under conditions of ample national supplies.

A major objective of family food consumption studies is to learn about socioeconomic and other conditions associated with low and high levels of food consumption and to study the importance of some of the factors affecting the nutritive adequacy of diets.

National Food Surveys

The most recent national survey of family food consumption was that of urban families in the spring of 1948 (1, 2). Also, in 1948 and 1949, seasonal data were collected in four cities (Birmingham, Buffalo, Minneapolis-St. Paul, and San Francisco) representing different sections of the United States (3, 4).

For comparisons, consumption data were obtained in 1950 from a small sample of rural

families in the Minnesota area (5). About the same time, five southern States, cooperating with the Bureau of Human Nutrition and Home Economics, completed a joint survey of farm family food consumption in the cotton, tobacco, and mountain areas of the South (6). Data from national samples of both urban and rural families are available for 1942 (7). The largest survey of food consumption on a nation-wide basis was made in 1936 (8, 9).

The 1936, 1942, and 1948 studies were made during different economic cycles in this country. The first was near the end of the depression of the 1930's. The second was on the eve of rationing in World War II. The 1948 studies were conducted during a war recovery period of high level food consumption in the country as a whole.

For these studies, random samples of families reported to trained interviewers the quantities of food purchased, home-produced, or otherwise acquired, and consumed within a specified period, usually a week. Enough details were given as to the kind, form, quality of the food, and composition of the household to make possible computations of nutritive value, comparisons with recommended allowances for dietary adequacy, and analyses of variations in consumption. The analyses were designed to show the levels of consumption by different socioeconomic classifications of the families, to identify the low-consuming groups, and to reveal the effect of low consumption of important foods on the adequacy of diets.

Comparisons of Food Consumed

Selected data from some of the analyses of food quantities consumed as reported in the

Dr. Coons, assistant chief of the Bureau of Human Nutrition and Home Economics of the United States Department of Agriculture, adapted the material for this paper in part from one presented at the Combined Conference on Administrative and Scientific Aspects of Food in Civil Defense, held in London, November 26 to December 13, 1951 (see Public Health Reports, July 1952, p. 607). Most of the data are taken from studies conducted by the Bureau of Human Nutrition and Home Economics.

1948 surveys are summarized in table 1. The first two lines of the table show the average national supply at retail for all consuming groups for the entire year of 1948 (10) in comparison with the quantities of food groups urban families consumed in the spring of 1948. Some differences would be expected from the nature of the two types of data. Citrus fruits, for example, were used in larger quantities by urban than by rural families, and grain products and sugar are used in greater quantities in winter than in other seasons. Even when based on data for all consuming groups the year around, the average per capita quantities of foods entering household kitchens would not be strictly comparable to those based on statistics of national food supplies at retail levels after allocations to military and foreign groups have been deducted. Some differences would

be expected because disproportionate amounts of a few commodities, for example, meats, go into commercial meals eaten by family members away from home, and other commodities, such as sugar, disappear into processed foods, including canned goods and bakery products.

More important than the average per capita figures for quantities of foods consumed, or for nutritive value of the diets of a national sample of families, is the magnitude of deviations from the average exhibited by subgroups and by individual families. Some of the variations are related to socioeconomic factors: income, household size and composition, seasons, urbanization, and national economic cycles, as shown in table 1 for foods consumed and in table 2 for nutrient content of diets. Different commodities and different nutrients are affected by the various factors studied. From these

¹ Data compiled from various published and unpublished sources. See (11).

² Unless otherwise specified, figures are for consumption by urban families of the United States for 1 week in the spring of 1948. Average incomes, based on 1947 income after Federal income tax, are given for each group unless a specified income class is selected for the comparison.

³ Data are for purchased quantities only, at similar average weekly food expense, \$7.21 and \$7.01 per person, for families without and with children. This occurred among families without children at incomes of \$2,000-2,999, 2.45 persons, and with children at \$5,000-7,499, 4.11 persons.

⁴ Comparison based on selected family types.

analyses, it has become possible to know where, when, and at what foods or nutrients to look for underconsuming groups of families.

Income and Family Diets

The effect of income on the adequacy of family diets is illustrated in figure 1 (11). In the spring of 1948, with incomes of \$1,000 to \$2,000, 50 percent of the urban families had diets meeting the National Research Council's allowance in calcium, 69 percent met NRC's allowance in ascorbic acid (vitamin C). With incomes of \$5,000 to \$7,500, 64 percent of the families met the allowance in calcium—88 percent in vitamin A.

Differences in the quantity of major foods making up these diets were even more marked

than the differences in their nutrient values. because, fortunately, many assortments of foods can combine to give an adequate diet.

Such figures show that income is an important factor in assuring an adequate diet and also that many low-income families do obtain needed quantities of important dietary essentials. The figures reveal also that adequate purchasing power does not necessarily mean adequate diet, since even high-income families had diets low in some essential nutrients.

The figures do point up the need for continued education to teach people how to obtain good diets and to convince them that something worth while might be gained by improving their customary food habits in line with the principles of good nutrition.

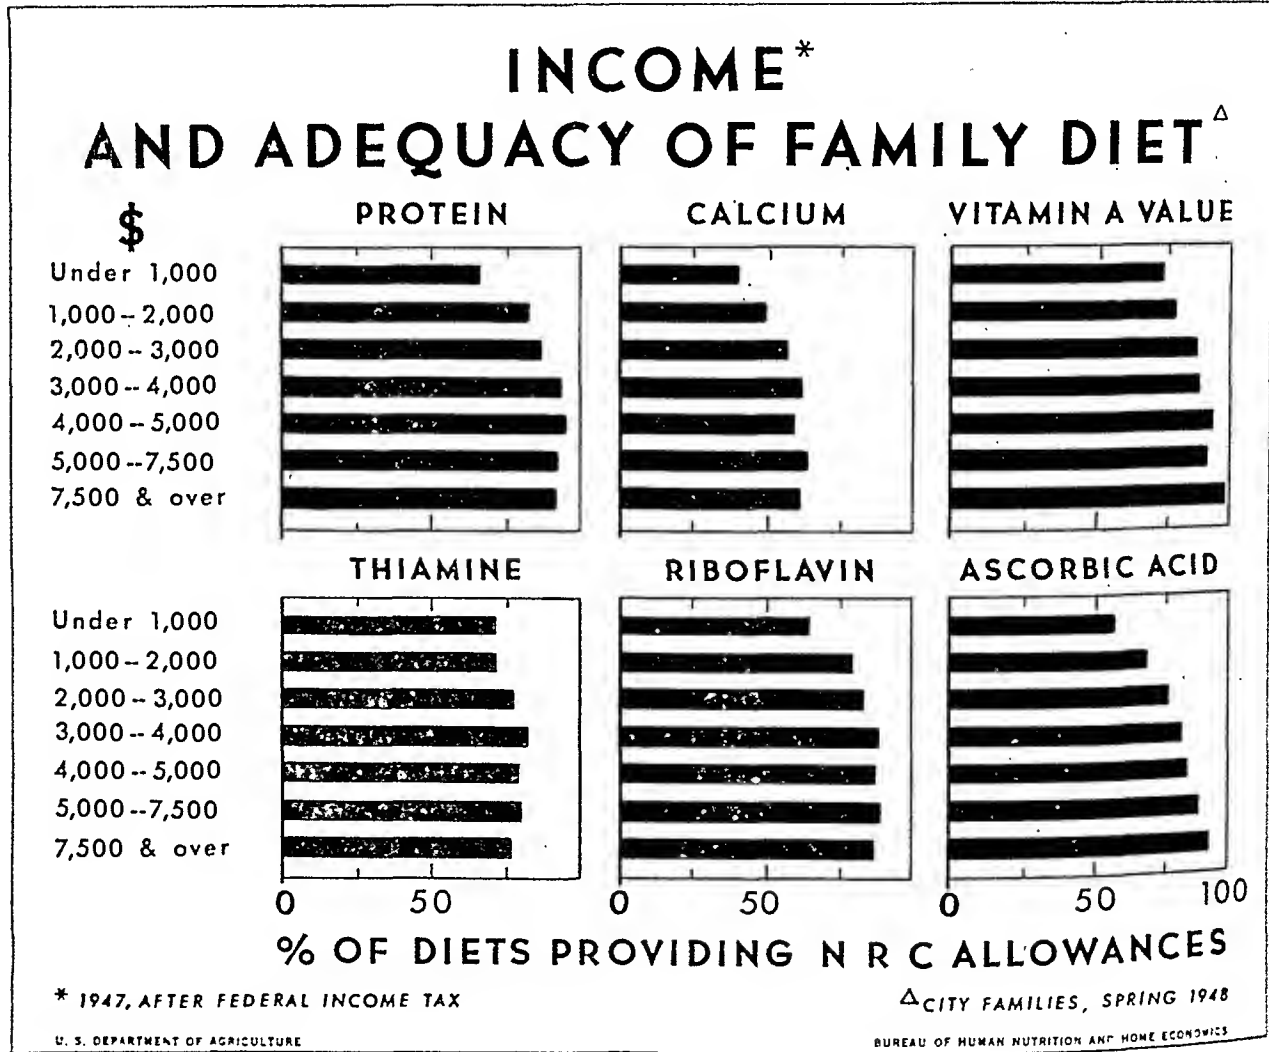

Figure 1.

FAMILY SIZE AND ADEQUACY OF FAMILY DIET*

U. S. DEPARTMENT OF AGRICULTURE

BUREAU OF HUMAN NUTRITION AND HOME ECONOMICS

Figure 2.

Differences in food habits associated with region and season made only small differences in adequacy of diets when incomes were comparable. Diets of rural families were particularly low in ascorbic acid due to low consumption of leafy green vegetables, citrus fruits, and tomatoes, but incomes were only about half those among urban families with better diets in the same area (tables 1 and 2).

Family Size and Diets

The relation of family size to the adequacy of diets may be seen in figure 2 for a selected income group. In general, large families of five or more persons had poorer diets until income levels of more than \$4,000 were reached. The large families then had diets about as good as smaller families except for calcium content.

At every income level, fewer large families

had diets adequate in calcium. Families with children under 16 tended to have somewhat better diets than those with no children, except at the lowest income levels. Even at the lower end of the income distribution, where the purchasing power available per family member was small in the large families with children, it was surprising that the nutritive quality of their diets compared so favorably with that of the smaller, childless families.

Education and Family Diet

The extent of the homemaker's education may explain some of the differences in skill of selecting good diets with a given income and expenditure for food (fig. 3). At less expense per person, college-educated homemakers obtained diets more adequate in all nutrients, particularly in calcium and ascorbic acid (vitamin C),

which are most often the limiting nutrients, than did homemakers of high school or elementary school education.

For example, in the spring of 1948, ascorbic acid was found adequate in 91 percent of the diets of urban families having homemakers with one or more years of college—in 83 percent

of those with high school education—and in 69 percent of those with only an elementary education. At that time, the average expense per person per week in 3-person families was \$7.12, \$7.52, and \$7.95 for families with homemakers of college, high school, and elementary school education, respectively.

¹ Data compiled from various published and unpublished sources. See (11). The nutritive value per nutrition unit (physically active man) per day of the food consumed at home by each household was computed and then compared with the National Research Council's recommended allowances for a physically active man (revised 1948).

² Unless otherwise specified, figures are for consumption by urban families of the United States for 1 week in the spring of 1948. Average incomes, based on 1947 income after Federal income tax, are given for each group unless a specified income class is selected for the comparison.

³ International units.

⁴ Estimated average cooking losses for the three B-vitamins and for ascorbic acid (vitamin C) were deducted from the aggregate value of foods consumed.

⁵ Comparison based on selected family types.

⁶ Data are for purchased quantities only, at similar average weekly food expense of \$7.21 and \$7.01 per person for families without and with children. This occurred among families without children at incomes of \$2,000-2,999, 2.45 persons, and with children at \$5,000-7,499, 4.11 persons.

Improvement in U. S. Diets

From 1942 to 1948, the improvement in diets occurred at all income levels but was most striking among the third of families with the lowest incomes. Some differences in food quantities consumed by the lowest income third are shown in the last two lines of table 1.

The impact of shifts in food choices in the 6-year period on over-all diet quality is best seen from a comparison of the nutritive values for diets of families in comparable income and family size groups, as shown in table 3 (2). In 1948, families in the lowest third of the income distribution had diets 14 to 35 percent higher in various nutrients (except vitamin A) than did corresponding families in 1942.

Higher calorie content of diets was attributable to greater use of vegetables, fruits, milk, eggs, meats, and sugar in 1948 than in 1942, more than offsetting a lower consumption of

potatoes and grain products. More calcium (20-percent increase for families of the lowest income third) was due to more milk in diets in 1948. More milk, eggs, and meats meant more protein, amounting to a 16-percent increase for families in the lowest third of incomes. A 16-percent increase also in ascorbic acid value of diets of families with lowest incomes was attributable to greater use of citrus, other fruits, and fresh vegetables. Families in the middle and highest income thirds had about the same or slightly less ascorbic acid in 1948 than in 1942.

Estimated quantities of three B-vitamins (thiamine, riboflavin, and niacin) were higher by 28 to 35 percent in diets of the third of families with lowest incomes in 1948 than in those of the lowest third in 1942. Increases of only 12 to 21 percent occurred for families in the middle and highest thirds. One reason for the greater gains of the lowest income third was

Table 3. Nutritive value of diets, 1948 and 1942, by income—average nutritive value per nutrition unit per day of food consumed at home, urban housekeeping families of two or more persons, by income thirds, United States, spring 1948 and spring 1942¹

Figure 3.

their 20-percent increase in meat consumption compared to little or no change for the middle and highest thirds.

Another reason was the enrichment of white bread and flour, since grain products contribute a larger share of nutrients in diets of low-income families than in diets of high-income families. Even without enrichment of bread and flour, the amounts of iron and niacin in family diets in 1948 would, on the average, have been 8 percent higher, and thiamine would have been 11 percent higher, due to greater consumption of meats, poultry, eggs, and some vegetables and fruits.

Riboflavin would have been 18 percent higher in 1948 than in 1942 without the benefit of stepped-up enrichment, chiefly because of the increased consumption of milk and many milk

products. Enrichment was responsible for 11 percent of the iron and niacin averaged in urban diets in 1948, and for 14 percent of the thiamine, and 3 percent of the riboflavin (11). The effect of enrichment on the nutrient content of the national food supply during the war years and thereafter may be seen in figure 4.

Conclusion

Surveys of family food consumption may be used as a basis for planning national and family food supplies, industrial and school lunch feeding, and nutrition education of families and individuals.

Whether the surveys are local, State, regional, or national, underconsuming groups are most likely found among low-income fam-

NUTRIENTS

In National Food Supply, 1935-51*

BUREAU OF HUMAN NUTRITION AND HOME ECONOMICS

Figure 4.

families of large size with homemakers of less than high school education. But small families with high incomes and college-educated homemakers often have diets that do not meet nutrition allowances in several nutrients.

Low dietary quality can usually be predicted from the consumption of milk and the fruits and vegetables rich in vitamin C. The figures for calcium and ascorbic acid content of diets are usually most indicative of nutritive adequacy.

New Heart Radio Series

"The Human Heart," a new series of eight quarter-hour dramatic radio transcriptions, is available for use in community health education. The series reports on progress in the treatment of various types of cardiovascular diseases.

The programs are designed for weekly broadcast over local radio stations by health departments and interested civic groups. Provision is made throughout the series for local live announcements of community sponsorship. Any one of the programs, however, may be used for nonbroadcast purposes—in classrooms, for instance.

Each transcription dramatizes a typical experience with a serious heart or circulatory ailment, as portrayed by a well-known radio or screen actor. Each story approaches the individual adjustment problem from a personal point of view—the doctor's or the patient's—that of the father, the mother, or the child. A brief commentary by a physician guest speaker ends the programs.

One program, "The Beautiful Noise," tells the story of a child born with a heart defect who becomes part of normal neighborhood life after an operation. Another, "A Matter of Strategy," tells how warning angina pains persuaded an explosive baseball manager to manage his team in a more relaxed fashion.

Sponsored by the Public Health Service, Federal Security Agency, the series was prepared under the auspices of the National Heart Institute and the Division of Chronic Disease and Tuberculosis, in the Public Health Service, and with the cooperation of the American Heart Association. It was produced and is being distributed by the Communication Materials Center, a division of Columbia University Press, 413 West 117th Street, New York 27, N. Y.

Drug Experience in Two Programs For Medical Care

By HERBERT NOTKIN, M.D., BETTIE ROGERSON, D.Sc., WILFRID DAVIS, M.D.,
and MATTHEW TABACK, M.A.

Drugs on a prescription basis, as well as home and office care by physicians, are provided low-income residents of Maryland, under two tax-supported medical care programs administered with funds allocated by annual appropriations of the State legislature.

The county medical care program, which operates in all Maryland counties, is administered jointly by the State Department of Health and the county health departments; the Baltimore City medical care program, confined to residents of Baltimore City, is administered by the Baltimore City Health Department.

Although the two programs differ basically in their manner of providing physicians' services, their drug policies are practically identical. Because the method of providing drugs is similar in both programs and their methods of payment are highly centralized, it has been possible to study some of the characteristics of this phase of medical care. Administrators of other medical care programs which supply or are contemplating the provision of drugs to their beneficiaries may find Maryland's experience helpful. Results of a careful evaluation of the ingredients noted on a sample of pre-

scriptions studied by a team associated with the Baltimore City medical care program will be discussed in a subsequent report.

County Medical Care Program

The county program, begun in 1945 and now in operation in all Maryland counties, provides physicians' services in the home and office, drugs—prescribed and dispensed—dental services, and hospital out-patient diagnostic services. All recipients of public assistance are automatically eligible for service. Medically indigent persons who are able to pay for their basic food, shelter, clothing, and similar needs but who are unable to pay for medical care are also eligible. Their eligibility is determined by the local health officer primarily on the basis of income, although exceptions may be made for medical or social reasons.

All professional participants in the program are paid on a fee-for-service basis, according to established fee schedules worked out with representatives of the professions involved. Patients have free choice of physician, dentist, and pharmacist, and those who provide service are free to accept or to reject patients.

Baltimore City Medical Care Program

The Baltimore City program, in operation since 1948, provides clinic services, home and office services by physicians, prescribed drugs, and emergency dental care to recipients of public assistance in the city. The method of providing physicians' services contrasts sharply

Dr. Notkin is assistant chief and Dr. Rogerson is a biostatistician in the bureau of medical services and hospitals, Maryland State Department of Health. Dr. Davis is the director of the medical care section and Mr. Taback is director of the bureau of biostatistics, Baltimore City Health Department.

with the county program. Each beneficiary is assigned to one of the medical care clinics operated by six of the large hospitals in the city. At the clinic he receives a physical examination and selects a physician from a list of those participating in the program. Thereafter he is under the care of the chosen physician, who receives a summary of the findings of the clinic examination and to whom the services of the clinic are available for consultation.

Physicians are paid on a quarterly capitation basis—a predetermined sum paid quarterly in advance for each patient accepted.

Provision of Drugs

The two programs have similar drug policies. Prescriptions are written on a special form, which is similar for both programs. The patient has the prescription filled at any pharmacy which cooperates with the program. The pharmacist bills the program according to the following established fee schedule:

The program pays for the wholesale cost of the drug, plus the cost of container, plus a specified mark-up—\$0.35 for uncompounded prescriptions and \$0.50 for compounded prescriptions whose ingredient plus container cost total less than \$2.50. For prescriptions with an ingredient-plus-container cost of more than \$2.50, a 30-percent mark-up is allowed. The two exceptions to this schedule are: (1) the programs will in no case pay more than the current retail price for a drug, and (2) insulin is paid for at the minimum fair trade price.

In general, physicians have complete freedom in prescribing drugs. However, both pro-

grams urge the use of U. S. Pharmacopeia and National Formulary drugs. The few limitations on freedom of prescribing are slightly different for the two programs. The county program does not allow payment for *spiritus frumenti*, streptomycin, or highly experimental and expensive drugs such as cortisone, ACTH, and pregnenelone. In the city program, all drugs with the exception of *spiritus frumenti* may be prescribed, but expensive or unusual drugs require approval of a clinic or of the program director.

In addition to prescriptions, when the cost of dispensed drugs is 50 cents or more the county program allows physicians to bill them at cost. Although this procedure is fairly widely used in some of the rural areas of the State, the cost of dispensed drugs during 1951 totaled \$11,746, only 6 percent of the total drug cost of the program.

Drug Data

County Medical Care Program

The more important indexes of pharmacy service provided by the county medical care program from 1946 through 1951 are shown in table 1. The total payments for all professional services are included to show the relative amounts of services provided. The striking feature of this table is the continuous increase in all the indexes of pharmacy service. Expenditures for prescribed drugs have risen out of proportion to expenditures for all services.

Table 1. Pharmacy services in the Maryland county medical care program, 1946-51

Selected data	Calendar year					
	1946	1947	1948	1949	1950	1951

Average number pharmacy invoices per 100 physicians' calls.....	43	45	56	63	70	66

¹ This represents billings. Payments to physicians, dentists, and hospitals prorated at 70 percent for 4 months.
² For 9 months only, January-September 1946.

In 1946, pharmacy costs were only 13.8 percent of the cost of all services. By 1951, they constituted about 25 percent of the costs of all services. The slight increase in percentage of pharmacy payments from 1950 to 1951 should be noted. This is the first time in the history of the program that there was not a marked rise in this index.

The increase in the average cost per prescription, from \$1.15 in 1946 to \$1.50 in 1951, is one factor contributing to this picture. Only one minor change in the pharmacist's mark-up fee has been made during this period, and the increase in average cost of prescriptions reflects both general wholesale price rises and the widening use of more expensive drugs.

There is, however, another trend which adds to the rapidly mounting drug costs. Physicians are now writing more prescriptions per call than they did 4 years ago. In 1946, 43 prescriptions were written per 100 physicians' calls. By 1950, 70 prescriptions were being written for each 100 physicians' calls. By 1951, however, this index had dropped to 66 prescriptions per 100 physicians' calls. This is the first time that a decrease has been observed in any index of pharmacy service. Together with the leveling off of the percentage of total payments for pharmacy service, this may presage a stabilization of pharmacy expenditures. A moderate program (see summary) of information for cooperating physicians concerned with the economics of drug distribution may serve to keep drug utilization at the lowest level consistent with good medical practice.

Uncompounded prescriptions make up the bulk of the drugs supplied. During 1951, 88 percent of all prescriptions were of this type. Refills constituted approximately 13 percent of all prescriptions, a figure well below the estimated 29 percent for prescriptions filled by all pharmacies in the State in 1950. Of the \$170,221 spent for services rendered by pharmacies in 1951, 66.7 percent represented the cost of the ingredients; 4.3 percent, container costs; and the remaining 29.0 percent, mark-up fees to pharmacists in return for professional services rendered.

In 1951 for persons receiving public assistance, the per capita cost of providing prescribed drugs was \$6.12, an average of 4.3 prescriptions

per person. Unfortunately, it is not possible to determine this index on an age specific basis at this time.

Nearly 93 percent of all licensed pharmacies in the counties filled prescriptions for the program during 1951. Pharmacists in Baltimore City, the District of Columbia, and States adjacent to Maryland also participated. Table 2 shows the distribution of pharmacies by location and number of prescriptions filled. As might be expected, the majority of the participating pharmacies are located in the counties of Maryland. However, a substantial number of out-of-county pharmacies also rendered service under the program.

There is a marked difference in the extent of participation of various pharmacies. Over a fifth of all participating pharmacies filled less than 10 prescriptions each in the year. At the other extreme, 34 pharmacies filled more than 1,000 prescriptions each during 1951, with 2 filling more than 4,000 prescriptions.

Consideration of the drug-dispensing characteristics of the program shows a pattern which indicates that a small or moderate volume of service is provided by most of the participating pharmacies, and a large volume of service is given by a relatively small number.

Baltimore City Medical Care Program

Since the Baltimore City medical care program has been in operation only since 1948, and

Table 2. Distribution of participating pharmacies by location of pharmacy and number of prescriptions filled, Maryland county medical care program, 1951

Average payment per invoice.....	\$1. 76	\$1. 45	\$1. 50

did not get fully under way until 1950, the historical picture is by no means as complete as that for the county medical care program. However, the comparable available data for the past three fiscal years are shown in table 3. No data are available on the number of prescriptions per physician's call, as the capitation feature of the city program has not furnished complete statistics on the volume of physicians' services rendered in the home or office.

During the early formative period of a medical care program, experience tends to be biased by the fact that persons with chronic or severe illnesses are usually the first to obtain care. The experience of the city program in 1948-49 and early in 1949-50 reflects this bias. The average cost per prescription in 1948-49 was higher than in the other 2 years, which in all probability is due to a high proportion of such expensive drugs as insulin provided in the first year of operation. The later experience of 1949-50 is considered to be fairly representative.

As can be seen from a comparison of tables 1 and 3, both programs spent approximately one-fourth of all funds for the provision of prescribed drugs during the years for which the most recent data are available. The average cost per prescription was exactly the same for this period.

Insofar as the type of prescription is concerned, the experience of the two programs was comparable. Of all prescriptions supplied by the city program in 1950-51, 81 percent were uncompounded, compared to 88 percent under the county program. The experience of both programs was similar in that the average cost of compounded was less than that of uncompounded prescriptions despite a higher mark-up

fee, due to lower costs of ingredients in compounded prescriptions.

Table 4 shows the utilization of drugs, by age groups, in the Baltimore City program based on a sample of the assigned population on July 1, 1949. Similar data are not available for the county program. On the average, 3.1 prescriptions were written per person per year. The importance of the age distribution of the population is emphasized by the differences in the age specific rates. The number of prescriptions per person for people in the older age groups considerably exceeds that for younger persons. As a general rule, populations consisting of public assistance recipients are weighted with people in the older age groups, a fact which adversely influences the over-all cost of providing drugs to such populations.

The distribution of pharmacies cooperating with the Baltimore City program, by location

and number of prescriptions filled, is seen in table 5. Only 5 of the 342 participating pharmacies are located outside of Baltimore City. As is true in the county program, there is wide deviation as to the extent of participation. In general, most pharmacies rendered a moderate volume of service with relatively few filling a large number of prescriptions.

Summary

Some of the experiences of the Maryland county medical care program and the Baltimore City medical care program in providing prescribed drugs to beneficiaries are analyzed. Although physicians are paid on a fee-for-service basis by the county medical care program and on a capitation basis by the city program, the drug policies of the two programs are similar. With few exceptions, physicians have complete freedom in prescribing drugs.

Neither of the programs has been willing to restrict this freedom. However, in an effort to counteract the rising cost of drugs to some extent, administrators of both programs

have written to all participating physicians urging economy in the prescription of drugs. The county medical care program campaign was carried out primarily in the summer of 1950 and may account to some extent for the leveling off of drug expenditures in 1951. The Baltimore City program campaign was not instituted until the summer of 1951, and therefore its results are not reflected in the statistical material presented here.

The county program has been in operation since 1945. A historical review of drug costs from 1946 through 1951 shows a marked increase both in the numbers of prescriptions supplied and the total dollars spent for prescribed drugs. The percentage of total expenditures devoted to prescribed drugs has been increasing steadily. Contributing to this fact is a rise in the average cost per prescription over the years and an increase in the number of prescriptions written per physician's call. There are some indications that drug costs have reached a peak.

During the past year, both programs spent for prescribed drugs approximately 25 percent of their funds for all services. Between 80 and 90 percent of these expenditures were for uncompounded prescriptions. The average cost per prescription was \$1.50 in 1951 for the county program and in the fiscal year 1950-51 for the city program.

The experience of the city program emphasizes the importance of the age distribution of the population served in determining overall drug costs. The number of prescriptions per person per year shows a marked variation with age. Persons in the older age groups receive a considerably larger volume of pharmacy service than do those in the younger age groups.

The participating pharmacists under both programs present a similar pattern in the extent of participation. Most participating pharmacies provided a small or moderate volume of service under the program, with relatively few pharmacies filling more than 3,000 prescriptions in a year.

Refuse-Can Holders

By RALPH J. VAN DERWERKER, B.S., and
CHARLES C. JOHNSON, Jr., B.S.

Sanitary storage of refuse is a desirable goal for every community. It has been reported that the author of a well-known guide to fine eating places will not enter a restaurant until after he has inspected and approved its refuse-storage facilities and practices. Likewise, the desirability of a community or a neighborhood may be measured, not by its front lawns, but by its back yards. The refuse-can holder, rack, or stand is a recently developed device which aids materially in maintaining sanitary refuse-storage conditions.

Refuse Sanitation Problems

Many elements of the community agree on the importance of promoting and maintaining a sound, community-wide, refuse-storage policy and practice. Public health authorities acknowledge the significance of refuse sanitation by initiating periodic clean-up campaigns and by issuing and enforcing regulations governing the storage of refuse awaiting collection. Public works authorities are interested in having refuse confined in proper containers and located at the proper places for collection. The fire department, too, has a legitimate concern in the safe storage and collection of combustible refuse.

Most communities have regulations requiring garbage and other refuse to be placed in water-

tight metal containers—5- to 10-gallon containers for garbage and 20- to 24-gallon containers for rubbish, or 30-gallon containers where combined storage is permitted. Such regulations, however, do not solve the problems that arise from the tipping over of containers or the investigation of their contents by dogs or children. Likewise, the problems of deterioration of cans by rust and of accumulations of rotting refuse under cans resting on the ground have seldom been resolved by the existing regulations. The use of refuse-can holders or stands is proving a satisfactory answer to these problems in several communities.

Past Experience

Some years ago, the concrete platform was promoted by authorities to eliminate the problems of rust and unsanitary conditions where cans rest on the ground (1). However, rodents burrowed underneath these platforms, which provided them with excellent harborage conveniently located near a supply of food. The construction of a 2-foot curtain wall below and around the platform will eliminate this disadvantage, but home owners are likely to balk at the added expense. A container platform with the curtain wall can probably be used to best advantage in multiple-dwelling projects and business areas, where it may be constructed large enough to hold several containers.

Underground, vaultlike structures have also been tried. These structures consist of a cylinder into which the refuse can is lowered and a cover which fits over the cylinder, flush with the ground. The disadvantages of the vaults, however, often outweigh the advantages, espe-

Mr. Van Derwerker is the chief and Mr. Johnson is an engineer in the municipal and rural sanitation branch of the Division of Sanitation, Bureau of State Services, Public Health Service.

cially where the ground water is high. Sunk-en cans, therefore, are recommended only where soil drainage is especially suitable or direct drainage is provided.

Frame or boxlike enclosures have long been used to conceal and protect refuse cans and, occasionally, loose refuse. Experience has shown that such structures generally attract rodents and flies because they are difficult to keep clean. Furthermore, people are inclined to use them as substitutes for an adequate number of good quality cans. The best devices for hiding and protecting refuse containers do not result in sanitary conditions, unless, of course, they are adequately maintained.

Essential Requirements for Holders

Sanitary storage of refuse requires a water-tight metal container equipped with handles and a tight-fitting cover. Without additional safeguards, however, the benefits of such containers may be minimized. Refuse containers that are kept out of doors should be kept on some type of holder. A good refuse-container holder is one that is convenient for both the householder and the collection crew. It should raise the can at least 12 inches from the ground to allow adequate space for cleaning underneath the can and to prevent rodents from harboring under it (2). Circulation of air across the bot-

Figure 1. Refuse cans held on steel hooks.

Figure 2. Refuse-can holder consisting of steel post and hooks.

tom of the can keeps it dry and helps to prevent corrosion. The holder should provide support of the can to prevent its being tipped over by dogs or children. Finally, it should be made of a durable material, one that is not subject to excessive deterioration as a result of varying types of climatic conditions.

Recommended Holders

There are several types of commercial stands and holders which meet these requirements. One of the simplest is a steel hook that can be fastened to the house or to a fence post (fig. 1). Another type comes complete with a steel post, hooks, and sometimes a chain for the can cover (fig. 2). The post need only be set in the ground in a convenient place to be ready for use. Some housing developments are providing such container racks as standard equip-

ment for the tenants. The neat rows of refuse containers and the cleanliness of the community are results that are immediately noticed.

A more substantial stand, which has been used in some communities, is constructed of pipe and pipe fittings. Once the pipe is cut and threaded, it can easily be assembled by the householder. Lengths of pipe or reinforcing steel may also be welded together to make a stand (figs. 3 and 4). Because these stands are made of metal and have rigid joints, they can be considered permanent.

Though somewhat less durable, stands constructed of lumber are also being widely used. Some health departments have distributed plans to make it easy for the householder to construct these stands at home. The Public Health Service has also suggested such a stand. In figure 5 are a list of materials and diagrams for its construction. This stand is designed to hold a standard container of 30-gallon capacity; where cans of smaller capacity are used, the dimensions should be made smaller so that the can will be held securely in place. The recently completed film by the Public Health Service,

Figure 3. One-can stand made of reinforcing steel welded together.

"Sanitary Storage and Collection of Refuse," portrays the use and advantages of this type of stand (see p. 787, this issue of *Public Health Reports*).

Promoting Community Programs

The first step in stimulating community interest in refuse sanitation is the dissemination of information regarding the hazards of insanitary conditions. Citizens should be informed of the danger of diseases borne by flies, rats, and other pests that breed or find harbor-age in improperly stored garbage and rubbish (3). Broken glass, tin cans, and bottles (sometimes containing residual poisons or unwanted medicines) constitute serious accident hazards. Wood, rags, paper, and other combustible rubbish are fire hazards. Obnoxious sights and odors can depreciate property values. Hidden costs of improper refuse storage include higher medical and hospital bills, higher insurance rates, and higher taxes.

Specific campaigns, of course, will depend largely upon the community involved—its economic status, its percentage of home owners, and the educational level of its citizens. Municipal authorities should not find it too difficult, however, to enlist the aid of the many diverse elements of the community which are directly or indirectly concerned with the problem.

Local public information media, such as community newspapers and radio stations, can be urged to contribute space and time as a public service. Civic organizations (Rotary, Kiwanis, Lions), business organizations (chambers of commerce, boards of trade, neighborhood associations), women's organizations, parent-teacher associations, garden clubs, professional associations (especially those related to medicine), and many others can be shown to have a personal interest.

The Public Health Service has published a leaflet (Public Health Service Publication No. 183) which contains recommendations concerning the proper storage of refuse by the householder. This leaflet could be distributed throughout a community as an aid in promoting good practice. The leaflet, entitled "Safe and Sanitary Home Refuse Storage," can be purchased from the Superintendent of Documents, Government Printing Office, Washington 25, D. C., for \$1 per 100 copies. The Public Health Service film mentioned above will also be found useful in community programs for promoting refuse sanitation.

Current Programs

That campaigns for sanitary refuse-can holders can be successful is attested by such communities as Watertown, S. Dak., where it

Courtesy Oklahoma State Department of Health

Figure 4. Multiple-can stand made of pipe with welded joints.

is reported that half of the population of 18,000 now have them. In Cleveland, Ohio, the city health department assembles holders from welded reinforcing steel and sells them to householders at a very reasonable price. Waynesboro, Va., has successfully encouraged the use of pipestand holders on a community-wide basis.

ONE CAN GARBAGE STAND

Figure 5. Diagrams and materials for construction of wooden stand to hold 30-gallon refuse can.

In Rapid City, S. Dak., a citizen placed a refuse-can holder on his front lawn to demonstrate its desirable qualities; as a result, many others in the city began using holders. Mandan, N. Dak., encourages the use of stands as part of its refuse sanitation program, which was initiated in conjunction with the recently

completed city-State-Public Health Service demonstration of a sanitary landfill. The Oklahoma State Department of Health is also promoting the use of refuse-can racks throughout the State (4).

In many instances, the acceptance of the principles of refuse-can racks or holders by the residents of a community has led swiftly to a general improvement in sanitation practices in other respects.

Summary.

The use of refuse-can holders appears to be the best answer thus far to the problem of protecting the cans from excessive rust, from being tampered with by children, and from invasion by pets or vermin. Since refuse-can holders keep the cans off the ground with sufficient clearance for good housekeeping of the area, the accumulation of rotting refuse rarely occurs. The orderliness developed by the use of holders in turn helps to beautify the surroundings.

Two Surveys of Disabling Illness

By THEODORE D. WOOLSEY, B.A.

New estimates of the prevalence of disabling illness among persons aged 14 to 64 years in the United States have recently been compiled from the results of two sample surveys, identical in plan, undertaken in February 1949 and September 1950. The findings of the first of these surveys have been available for some time (1, 2), but users of the data were cautioned to take into account the fact that the amount of illness in the country is usually at or near the top of the seasonal cycle in February. The statistics presented for February 1949, therefore, overestimated the amount of disabling illness that one would find in the United States on an average day. On the basis of that survey it was estimated that 4.6 million persons between the ages of 14 and 64 years, inclusive, were unable to carry on their usual activities because of some illness or other medical condition.

As had been expected, the second survey revealed a lower prevalence (table 1). In September 1950, the estimate indicated that slightly more than 3.6 million persons aged 14 to 64 were disabled, using the same criteria of inability to carry on usual activities. Most of the difference between the two figures was in the cases of illness of short duration, that is, the cases for which disability had lasted a month or less. Many of these illnesses were probably the minor respiratory infections which are responsible for the greater part of the seasonal differences.

On the other hand, the number of persons who, at the time of the survey, had been disabled for more than 3 months was not greatly different in September 1950 from the corresponding number in February 1949. The estimate from the earlier survey was 2.3 million and from the later survey, 2.2 million. These

This article is a summary of the principal findings presented in Public Health Monograph No. 4, published concurrently with this issue of *Public Health Reports*. The author is a biostatistician in the Division of Public Health Methods, Public Health Service.

Readers wishing the data in full may purchase copies of the monograph from the Superintendent of Documents. A limited number of free copies are available to official agencies and others directly concerned on specific request to the Public Inquiries Branch, Public Health Service. Copies will be found also in the libraries of professional schools and the major universities, and in selected public libraries.

Woolsey, Theodore D.: Estimates of disabling illness prevalence in the United States. Based on the Current Population Survey of February 1949 and September 1950. Public Health Monograph No. 4 (Public Health Service Publication No. 181). U. S. Government Printing Office, Washington, 1952. Price 15 cents.

must have been chiefly chronic disabling cases, and the stability of the number is in accordance with expectation.

A comparison of the numbers of persons dis-

abled for more than 3 months (lower half of table 1) and the numbers of all persons found to be disabled (upper half) indicates that the cases of longer duration form a proportion of the total that (a) increases steadily with age; (b) is higher in September than in February; and (c) is higher for males than for females.

The surveys did not cover the population of resident institutions, such as hospitals for mental disease, tuberculosis sanatoriums, homes for the aged, and orphanages. The number of disabled persons 14 to 64 years of age in these institutions is estimated at roughly 750,000. Most of these have undoubtedly been disabled for more than 3 months, and, hence, would have appeared in the lower part of table 1, as well as in the upper part, if they had been included in the survey.

In addition to supplying national estimates of the numbers of disabled persons, the two

surveys also afford an opportunity to make comparisons of the prevalence of disabling illness in the main age and sex groups of the population aged 14 to 64 years and in urban, rural, and employment status categories. Tables 2 and 3 shown here are abstracted from Public Health Monograph No. 4 in which the findings from the September 1950 survey are brought together with those from the survey of February 1949, and the averages of the prevalence rates from the two surveys combined are presented in greater detail than is possible here.

The data in table 2 reveal three points which are worthy of particular attention. First, there is the high prevalence of disabling illness among males at ages 45 years and over. A higher rate for males than for females has been observed in previous surveys but not for males as young as 45 to 54 years. Second, there is a rather striking excess of disabling illness among

¹ See footnote 1, table 1.

unmarried women in all age groups from 25 years on compared with rates for married women in the same age groups. This, too, is a relationship that has been observed before, although no completely convincing explanation has been given for it. Finally, a consistent and not unexpected disadvantage of the nonwhite population with respect to disabling illness shows up clearly in the prevalence rates.

The rates in table 2 are based on cases of disabling illness of all prior durations. This means the rates include cases in which the dis-

ability had lasted as short a time as one day and other cases in which the person had been continuously unable to work for as long as 10 years, or had even been completely disabled since birth. The rates in table 3, on the other hand, are averages for the two surveys of the percentages of persons aged 14 to 64 who had been disabled for more than 3 months.

For these chronic disabling cases it is apparent that the rates for males are higher than those for females at all ages included in the survey. The ratio of male to female prevalence ranges

Table 3. Estimated percentage¹ of persons in the civilian noninstitutional population disabled for over 3 months at the time of the survey, by age, sex, and race, United States, February 1949 and September 1950 combined

¹ See footnote 1, table 1.

between 1.45 and 2.00 in the six age groups shown. In these same six age groups the ratio of male to female mortality from all causes of death ranges from 1.47 to 1.74. In general, there is a noticeable similarity of pattern between the distribution of the disabling illness of longer duration by age, sex, and race and that of mortality in the same groups.

Public Health Monograph No. 4 provides rates for the duration categories in greater detail and also gives average rates of prevalence by employment status and urban, rural nonfarm, and rural farm residence. Tables of sampling errors for use in making rough tests of significance are also presented.

Field work and statistical processing for the two surveys were done by the Bureau of the

Census at the request of the Public Health Service, the Social Security Administration, and the Office of Vocational Rehabilitation, Federal Security Agency. A description of the survey, the definitions used, the sampling errors, and other essential features of the data are contained in the references listed here and in the monograph.

Beginning with Monograph No. 3, the size of the volumes was standardized. Format of future monographs will be similar to that of Monograph No. 4.

Leptospiral Etiology of Fort Bragg Fever

By WILLIAM S. GOCHENOUR, Jr., V.M.D., JOSEPH E. SMADEL, M.D., ELIZABETH B. JACKSON, A.B.,
LaRUE B. EVANS, B.S., and ROBERT H. YAGER, V.M.D.

Fort Bragg fever, or pretibial fever, was originally observed during the summer of 1942 in troops in North Carolina. Forty cases occurred that summer, and approximately the same number were diagnosed during each of the next two summers.

The disease, as described by Daniels and Grennan (1), was a nonfatal febrile illness of approximately 5 days' duration, associated with headache, malaise, and splenomegaly. The most distinctive feature of the disease was the appearance of an erythematous rash on about the fourth day of illness; this rash was usually limited to the pretibial areas of both legs.

Early Investigations

From the blood of one of the acutely ill patients in 1944, Tatlock (2) recovered an infectious agent which induced a fatal disease in hamsters, a mild febrile illness in guinea pigs

Major Gochenour is chief of the department of veterinary bacteriology, veterinary division, Army Medical Service Graduate School, Walter Reed Army Medical Center, Washington, D. C., and assistant director of the division; Dr. Smadel is director of the communicable diseases division; Miss Jackson is in the division's department of virus and rickettsial diseases; Mr. Evans is a technician in the department of veterinary bacteriology; and Lieutenant Colonel Yager is director of the veterinary division.

This paper was presented, in part, at the thirty-sixth annual meeting of the Federation of American Societies for Experimental Biology, held in New York City, April 14-18, 1952.

and rabbits, and grew well in embryonated eggs. By means of neutralization tests performed in hamsters, he was able to show that specific antibodies against the agent appeared in the patients' serums during convalescence. However, various types of studies failed to show that the agent was related to a number of the more common viral and rickettsial agents.

In order to learn more about the disease-producing capacity of the agent in man, in 1946 Tatlock inoculated volunteers with material which had been through 80 passages in the guinea pig and 23 passages in the embryonated egg. The majority of these volunteers, after an incubation period of about a week, developed a mild illness indistinguishable from the naturally acquired Fort Bragg fever.

During the succeeding years, the agent of Fort Bragg fever was maintained intermittently in several laboratories. It was lost occasionally, and in general earned the reputation of being a difficult agent to transmit in serial passage. The possibility that this agent might be a leptospira was considered at several times, but results obtained with methods then employed failed to support the idea.

Recent Methods

Recently a large collection of leptospiral strains was assembled at the Army Medical Service Graduate School for other investigative work. In the fall of 1951, convalescent and immune serums were re-examined with antigens prepared from these strains, and a high level of agglutinating antibody against *Leptospira autumnalis* was demonstrated.

With this lead and the employment of suit-

able cultural techniques, a leptospiral organism was recovered from material of the 259th hamster passage of the Fort Bragg agent, which represented the 365th passage in guinea pigs, embryonated eggs, or hamsters since original isolation. Extensive cross-agglutination tests, with hyperimmune rabbit serums, indicated that the Fort Bragg agent was essentially indistinguishable from *L. autumnalis* Akiyami A, the cause of autumnal fever in Japan and the Far East. Both the Fort Bragg and the *L. autumnalis* strains were agglutinated to some extent by antisera against *Leptospira pomona*, *Leptospira sentot*, and *Leptospira icterohemorrhagiae*. However, none of the antisera against the remaining 12 prototype strains employed in the screening test studies agglutinated either the Fort Bragg or the autumnalis organism.

At this point there was no doubt that leptospirae of the *L. autumnalis* group were being carried in the laboratory under the designation of the "virus" of Fort Bragg fever. It was then important to establish whether this was a laboratory contaminant or whether it had indeed originated from patients with the clinical disease in North Carolina. We retraced the history of the Fort Bragg agent by means of leptospiral agglutination tests done on stored serums obtained from animals and men infected at various stages during serial passage of the agent.

Test Findings

Dr. Melnick (3) supplied paired serums from four chimpanzees which had developed a mild febrile illness following inoculation with the Fort Bragg agent in 1947. The results of his neutralization and our agglutination tests are presented in table 1. All four chimpanzees developed antibodies during convalescence. Neutralization tests were done in hamsters with the strain being carried in 1947 in New Haven, and the agglutination tests employed the Fort Bragg leptospira cultured at the Army Medical Service School in 1951.

The results of agglutination tests on paired serums from Tatlock's volunteers, who had been inoculated in Cincinnati in 1946, are presented in table 2 along with the results of neutraliza-

tion tests done on hamsters at the school during 1947 and 1948. Here again neutralizing antibodies against the hamster agent and agglutinins for the leptospira were developed.

Table 1. Serologic tests on chimpanzees infected with Fort Bragg agent in 1947

Animal	Hamster neutralization index ¹		Agglutinin titer with Fort Bragg leptospiral antigen	
	Acute	Convalescent	Acute	Convalescent
Rosebud-----	0	100	0	400
Mary Lou-----	0	100	0	1,600
Hickory-----	0	100	0	1,600
Catawba-----	0	100	0	6,400

¹ Data from reference 3.

Stored, frozen, paired serums were still available from five of the original soldiers who had been bled during the North Carolina outbreak of 1944. The group included patient A from whose blood the agent of Fort Bragg fever had

² Tests made in 1951.

been originally isolated. The data in table 3 show that patients A, B, and C developed neutralizing antibodies and leptospiral agglutinins during convalescence from naturally acquired Fort Bragg fever. It is of interest that patients D and E, who in Tatlock's experience failed to develop neutralizing antibodies, also failed to develop agglutinins.

With portions of convalescent serums, from patients A, B, and E, which had been frozen and stored from 1944 until January 1952, the neutralization tests were repeated, using brain tissue from the 292nd serial hamster passage of the Fort Bragg agent. Essentially the same results were recorded in this test as had been obtained 5 years before by Tatlock using material from early passages of the agent. The data from these tests are summarized in table 4.

Of equal interest are the data in table 4 on neutralization tests with rabbit hyperimmune serums. One of these antiserums was prepared in 1947 from the hamster line of the agent, another in 1951 from cultured leptospirae of the Fort Bragg agent, and the third from cultures of *L. autumnalis* Akiyami A. Each of these hyperimmune rabbit serums protected hamsters against at least 100,000 LD₅₀ of the Fort Bragg leptospira. In a similar serum protection test, hyperimmune rabbit serum prepared against *L. autumnalis* Akiyami A completely protected hamsters against subsequent challenge with the Fort Bragg leptospira, which was fatal to all nonimmunized animals.

The results of serologic tests on 45 other stored serums of soldiers ill with Fort Bragg fever are of interest even though paired serums

were not available from all patients. Eight of the 24 patients bled in 1943 and 8 of the 21 bled in 1944 presented clear-cut serologic evidence of infection with Fort Bragg leptospira.

Summary

Recently accumulated evidence indicates that Fort Bragg fever is a leptospiral infection caused by a member of the *L. autumnalis* group closely related to the type strain Akiyami A. Members of this group of leptospirae were not previously known to occur in the United States.

Genetic Control Of Metabolism

Bacterial viruses insofar as they contain genelike subunits are very much like bacteria or bread mold or men. A discussion of this subject as it relates to the genetic control of metabolic processes is contained in this publication, the first in the series of the R. E. Dyer lectures honoring the former director of the National Institutes of Health.

The author, George W. Beadle, Ph.D., who is from the Kerckhoff Laboratories of Biology, California Institute of Technology, received the Lasker Award in 1950 for his work along this line. Remarks of W. H. Sebrell, Jr., M. D., present director of the National Institutes of Health, who presided, and of James Stevens, M. D., Brig. General, USA (Ret.), and now Dean of the Harvard School of Public Health, who introduced the lecturer, are included in the publication.

In *Neurospora crassa*, the bread mold, many hundreds of specific metabolic defects have been produced through gene mutation. The existence in bacteria, the lecturer said, of mutations similar to the genes of higher organisms, has been demonstrated.

Genes as units of inheritance and of function are discussed. Certain inherited diseases in man suggesting a close relation between genes and protein specificities are:

1. Hemophilia, in which the serum protein of the gamma globulin fraction that plays a role in the blood-clotting mechanism appears to be absent or greatly reduced in its clotting activity.

2. Sickle-cell anemia, in which a defective form of a particular gene changes the electrophoretic mobility of the hemoglobin of the blood cells.

3. Alcaptonuria (to which hereditary idiocy is closely related) in which 2,5-dihydroxy-phenyl-acetic acid is not metabolized, but instead is excreted in the urine.

4. Galactosemia, a hereditary inability to utilize the specific sugar galactose.

The inheritance of diabetes mellitus is not clear. It is probable; nevertheless, the lecturer said, that the continued production of the normal amount of insulin is immediately dependent on the normal form of a specific gene.

Clean Water In the Missouri?

The Public Health Service, in July 1951, released a 212-page technical report on Water Pollution in the Missouri River Drainage Basin, the third in a series of 15 cooperative State-Federal drainage basin reports to consider the economic and health problems caused by water pollution in major streams and their tributaries in the United States.

"Clean Water in the Missouri?" briefly summarizes the long technical report, and in itself is one of a series of brief reviews of the technical studies.

Written in digest style, the pamphlet is intended for circulation far from the desks of health officers, and, at the same time, it has been planned to achieve basic understanding and to motivate action upon the pollution problems which cut across the boundary lines of city limits and State borders.

Three sample quotations:

... "The organic waste being poured into the Missouri and its branches is equivalent to the body wastes and other domestic wastes from 12 million people. About one-third comes from city sewers, the rest from industry."

... "From an industrial viewpoint, the waste problem centers about three kinds of industry: beet sugar, petroleum, and packing houses."

... "Nearly a thousand urban centers—979 according to the technical reports—are today emptying domestic waste into the Missouri and its tributaries. Only 383 have adequate treatment plants."

The pamphlet points to waste treatment plants as the solution for the pollution of water which has become unfit for drinking, cooking, washing, swimming, fishing, industrial, or farm use.

for the general public

Menopause

This leaflet describes the "change of life." The symptoms of the body adjustments taking place during the menopause period are explained. Caution is given against ancient superstitions which have caused unnecessary worry. Consultation with a doctor is advised for guidance through the menopause period in order to assure a minimum of physical and emotional discomfort. The leaflet emphasizes that there is nothing abnormal about the change of life.

Public Health in the Scientific Assembly Of the American Medical Association

Among the several hundred papers presented before the 101st Scientific Assembly of the American Medical Association in Chicago, June 9-13, 1952, there were a number dealing directly with public health topics. With the assistance of the Association, Public Health Reports selected from those papers, available in text or detailed summary form, several which appeared of more than casual importance to our readers. These are presented here in news summary form as a "conference report." The source of each report is stated, and it must be clear that the author—not the Public Health Service—is the authority in each instance.

PHR

Conference Report

Urges Acceptance of Occupational Medicine

Hoping that his address as chairman would "serve as industrial medicine's declaration of independence," Carey P. McCord, M.D., of the University of Michigan's Institute of Industrial Health, opened the sessions of the section on preventive and industrial medicine and public health.

This integrality, Dr. McCord stated, is necessary as a step toward industrial medicine's full acceptance by the medical profession, whose indifferent attitude he described as fostered by habit and tradition and "one of passive resistance springing from widespread unfamiliarity with the objectives, methods, and obligations of occupational medicine."

"Only the naive will contend that either occupational medicine or preventive medicine has been accorded full and hearty acceptance within the totality of the medical family," he said, in pointing out that the victim of this nonacceptance was not occupational nor preventive medicine

but the medical profession and the public.

Centers of Resistance

Dr. McCord "tagged" two loci as "passive resistance centers"—medicine at the average county medical society level and the clinical medical teaching center. "Since medical colleges eventually populate county medical societies," he continued, "possibly there exists but one locus.

"The need is for well-planned, persistent, patient, dramatic, honest instillation of the admirable in industrial medicine into every other segment of medicine," he said. "The onus lies within occupational medicine because of inadequate revelations to other portions of medicine."

To counteract confusion and to gain acceptance, Dr. McCord stated that occupational medicine must establish its identity and individuality. He pointed out that, to some, occupational medicine means just surgery, or but an aspect of public health, or only administration with emphasis on insurance and employment procedures.

"In homely parlance," he said, "oc-

cupational medicine has little more identity and individuality than one meaty morsel of good beef stew . . . and needs to leap from the hodgepodge of any beef stew state to the individuality of a good sirloin steak."

"Division" Status

Likening its status to the military division where self-containment is achieved, Dr. McCord claimed the division echelon in the medical world for occupational medicine. "Surgery and other clinical activities as conducted in industry, industrial hygiene, occupational disease control, and administration are but components of an integrality—occupational medicine," he stated.

The preventive medicine of occupational medicine, he stated, is the public health aspects it embraces. "Indubitably, occupational medicine heavily leans upon and profits by the community's organized public health since workers are citizens as well," he said. "Such leanings but reflect the dependence of occupational medicine, like all other branches of medicine, upon the com-

munity's public health protective ministrations to the community. The industrial physician and the public health officer are allies.

"The success of occupational medicine inescapably is linked with community health," he stated later.

Rapport With GP's

In an extension of his remarks, Dr. McCord called for closer rapport and alliance between the family doctor and the industrial physician. Their single objective, he said, was the worker's health, and examination shows there is no basis for any vague belief that in some manner the industrial physician interferes with commendable relations between the family physician and his patient's families.

"The scope of industrial medical activity is such that only those conditions of industrial causation or aggravation and emergencies become the recipients of medical consideration beyond diagnosis or impression," he pointed out. Also, the industrial physician promotes the interests of the family physician by referral of nonoccupational conditions and continually needs the guidance of the family physician in connection with work resumption and work capacity, he declared.

On medical student training, Dr. McCord asserted that "aridity as to preventive medicine runs deep in the sands of clinical medical education . . . the student ends his formal training days more than a little warped in his concepts as to just what is important to an awaiting health-needing world."

New York Study Shows Rehabilitation Pays

Presenting the results of a follow-up study of 208 rehabilitants, Howard A. Rusk, M.D., professor and chairman of the department of

physical medicine and rehabilitation, New York University College of Medicine, asserted that rehabilitation of severely handicapped persons pays dividends in dollars as well as in social returns. The study was made 1 year after the discharge in 1950 of the patients from the physical medicine and rehabilitation services of three New York hospitals.

In speaking before the physical medicine section, Dr. Rusk pointed out that an economic gain is made even if the results of rehabilitation are limited to increased self-care. "To teach a helpless person self-care releases other hands and often saves costly care of the individual in an institution or hospital," he said.

Ninety percent of the individuals studied derived some benefit from their rehabilitation experience, Dr. Rusk reported. Eliminating 14 who did not complete their rehabilitation program, this percentage is increased to 97.

Dramatic Results

He stated that the number of patients confined to wheel chairs and beds decreased from 68 percent to 32 percent of the total; the number incapable of even minimal self-care decreased from 65 percent to 15.5 percent; and the number able to do some kind of work increased from 17.2 percent to 67.1 percent.

Dr. Rusk reported that upon admission to the hospitals, only 19 of the 208 patients were employed, or in training for employment, whereas 1 year after discharge 80 were working or in training. Complete figures on the yearly earnings of those now employed were not available, but the economic net gain of 31 and the potential earnings of 18 in training were estimated at \$95,800.

Dr. Rusk emphasized that the study highlighted two problems in regard to rehabilitation: (1) providing an opportunity to all disabled men, women, and children for comprehensive rehabilitation training; and (2) closing the gap be-

tween rehabilitation and training on the one hand and service and social opportunity in the local community on the other.

"To set these people adrift with their problems in their helplessness is a waste not only of costly training but, more important, a waste of human courage and effort," Dr. Rusk concluded.

Antimicrobial Therapy Aids in Tuberculosis

In the treatment of tuberculosis, antimicrobial therapy has become indispensable and "should be carefully coordinated with other forms of treatment," David T. Carr, M.D., a physician at the Mayo Clinic in Rochester, Minn., told the section on internal medicine.

The older forms of therapy, such as rest, collapse, and excision, still must be used, Dr. Carr explained, but with the discovery of potent antituberculosis drugs, treatment has become more complex and has increased the need for physicians to specialize in pulmonary tuberculosis treatment.

The best regimen available today for most tuberculous patients is streptomycin or dihydrostreptomycin given intramuscularly two or three times a week and daily oral doses of para-aminosalicylic acid (PAS), Dr. Carr said. "Preliminary reports of studies indicate that treatment for a period of 1 year or longer is significantly more effective than for a shorter period," he stated.

The concurrent administration of two or more drugs has been shown to delay, or even to prevent, the emergence of drug-resistant strains of tubercle bacilli, Dr. Carr reported. Such a delay has been effected in the combined use of streptomycin and PAS, but further clinical investigations are needed.

Isonicotinic acid hydrazide, Dr.

Carr pointed out, is now considered to have therapeutic potentialities. He said that to overcome drug-resistant strains "possibly the concurrent administration of all three drugs will prove to be the most therapeutically effective regimen."

Arthritis—"Health Problem of First Order"

Three events within the past 5 years marked the beginning of a new era of medical study and practice in the field of arthritis, declared Russell M. Wilder, M.D., director of the National Institute of Arthritis and Metabolic Diseases, Public Health Service, addressing the section on preventive and industrial medicine and public health.

Describing arthritis and rheumatism as "an enormous drain upon the country's manpower and economic resources," Dr. Wilder said that approximately 7.5 million people in this country are afflicted and that the cost to the Nation is estimated at over a billion dollars a year. He regards the rheumatic diseases as a "public health problem of the first order."

A major step in the advance against arthritis was taken in April 1948, when the two fund-raising groups, the National Arthritis Research Foundation and the Detroit Fund for Crippling Diseases, were merged to form the Arthritis and Rheumatism Foundation and annual fund-raising campaigns on a nationwide scale were initiated, stated Dr. Wilder. The funds of the foundation, now the principal voluntary agency in this field, are used to support laboratory and clinical research, to sponsor professional and public education, and to provide facilities and services for treatment.

Dr. Wilder noted the discovery of the antirheumatic properties of cortisone and ACTH in 1949 as the second event. This discovery produced

hope that further research would provide physicians with means for effective treatment, even mass control of rheumatic disease.

Functions of NIAMD

The third event was the establishment of the National Institute of Arthritis and Metabolic Diseases in 1950, Dr. Wilder said. The new institute, superseding the Experimental Biology and Medicine Institute in the National Institutes of Health, is at present carrying out a twofold program: conducting research in the rheumatic and various metabolic diseases, and assisting and fostering research in non-Federal institutions through grants and fellowships. A third phase of the program—clinical investigations in arthritis and the metabolic diseases, such as diabetes—will begin when the new Clinical Center, now under construction, at the National Institutes of Health is completed.

The objective of arthritis research by all official and voluntary organizations, Dr. Wilder concluded, is to help physicians help their patients.

Periodic Check-ups Urged for Smokers

Because of the higher incidence of lung cancer among heavy smokers than nonsmokers, semiannual radiological examinations for every heavy smoker over 45 were urged by J. Winthrop Peabody, professor of respiratory diseases at Georgetown Medical School and chairman of the section on diseases of the chest. This might lead to detection of the disease in the operable stage, he said. "Until this is done, mortality will continue high."

A definite diagnosis of lung cancer is now possible in 85 percent of the cases even in the early stages, he stated.

Antibiotics, he pointed out, have produced the greatest change in the

treatment of pulmonary disease, adding:

"They serve as valuable adjunct therapy to the old proved methods, such as bed rest, proper diet, and collapse theory in tuberculosis, and have shortened the recovery period. Complications have been reduced in number and severity, and operations performed on patients formerly considered inoperable."

Prevention, early recognition, and therapy, he reported, have made a decided advance against tuberculosis, pneumonia, lung cancer, and other chest diseases.

During the last decade, Dr. Peabody said, radical changes in the treatment of chest disease have been brought about by the use of antimicrobial drugs, new surgical techniques, and improved methods of anesthesiology. Mass chest surveys have also proved of great value in the fight against tuberculosis.

Museum Advances Patient Education

Sixty thousand yearly visitors attests the progress the Cleveland Health Museum has made in patient education, Bruno Gebhard, M.D., director of the museum, told the section on preventive and industrial medicine and public health. This number represents a doubling in attendance since the program began 12 years ago. Membership, too, has risen from 800 in 1940, mostly doctors, to 2,200 now, including people in all walks of life, he reported.

Although physicians fear self-diagnosis on the part of their patients, Dr. Gebhard thinks that it always has been and always will be the patient who makes the first "diagnosis" and that it is the educated patient, steered by his physician, who is most likely to make the right one. People born with certain tendencies, he maintained, will become hypochondriacs with or without

health education; honest health education releases anxieties and encourages a more optimistic outlook.

Pointing out that "doctor" originally meant "teacher," Dr. Gebhard declared that the best education is from one person to another in a heart-to-heart talk, that is, from physician to patient. "Making the patient feel a participant," is accomplished primarily, he said, by talking things over and doing things together. Talking to patients is just as important as writing a prescription, he maintained.

Group Teaching

As a new approach to the frequently mentioned barrier between the physician and his patient caused by medical technology, Dr. Gebhard reminded physicians that since they were individuals who had lived and talked as men, it ought not be asking too much for them to remember these facts when they deal with men.

The advantages of group teaching have long been known to educators, Dr. Gebhard reminded his audience, and physicians are today making more and more use of this active "learning-participation." He noted particularly the educational meetings held for the subscribers of the Health Insurance Plan of Greater New York, described in the *Montefiore Hospital Medical Group Bulletin* as follows: "It is unlikely that patients and doctors anywhere have been drawn so close to each other that questions regarding the detail of practice, the relations between doctor and patient, and even the income of doctors, have been so freely asked and freely answered."

Hospital patients, Dr. Gebhard said, should get special attention regarding information about their illness and their health care. "Patient education in hospitals has to be carried on in an organized fashion; the modern hospital cannot leave it to the chance action of doctors and nurses."

Visual Aids

Dr. Gebhard emphasized the use of visual aids, as one of the media for patient education—pictures, charts, actual physical models. This medium is used extensively in the Cleveland Health Museum, he noted, but it may also be used in the doctor's office, in group teaching, and in the hospital.

In addition to visual forms of education, Dr. Gebhard reported that the Cleveland Health Museum uses radio and television programs, newsletters, and booklets.

"The content of patient education has a great scope," Dr. Gebhard stated. "Today, in developing the Cleveland Health Museum, we enter our thinking around the normal growth and development of the human life from birth to old age." Most people are healthy most of the time, and it is better health that people want, he maintained, not just being free from disease. "One of the underlying goals of the Cleveland Health Museum's many and varied activities," he commented, "is perfect understanding and faith between doctors and their patients." For this reason, he said, museum exhibits go beyond biology into personal health, with special emphasis on the "positive" rather than on the "negative" side of living.

Travel Spurs Interest In Tropical Diseases

Citing reasons for the increasing interest in the control of tropical diseases, Lowell T. Coggeshall, M.D., dean of the division of biological sciences at the University of Chicago, told the general scientific session, "Modern transportation is now capable of carrying within a matter of hours an ever-increasing number of visitors into some of the most unhealthful spots on the globe."

Dr. Coggeshall stated that it is possible for some travelers to enter a tropical area and return before the normal incubation period of a disease has elapsed. He pointed to the misconception that tropical diseases occur only in the tropics.

"Our industrial and business interests are increasing in foreign areas, and, with their development, a large number of highly susceptible individuals are constantly coming and going," Dr. Coggeshall said. "Further and more important," he added, "international commitments would seem to make our interest in tropical diseases a permanent rather than a temporary episode."

American physicians and health officers can expect to see more of the diseases which have been considered rare in this country, according to Dr. Coggeshall, because of the rapid turnover of American troops in Korea and the frequent trips of Americans into some of the most insalubrious areas of the world. For these reasons, the American physician and health officer need "to keep more familiar with the advances being made by the scientists."

Dr. Coggeshall contrasted the great progress of today in the control of malaria, the rickettsial group, and plague with conditions of 15 years ago when there were practically no investigative programs. Tuberculosis, he added, because of its peculiar manifestations in the tropics, would seem to profit most if the recently discovered drugs prove to possess the therapeutic values now visualized. He mentioned that research projects are being conducted in many areas of the world by the medical departments of the armed services, pharmaceutical houses, foundations, and universities.

Several other tropical diseases which Dr. Coggeshall listed as menacing to the visitor to hot countries are schistosomiasis, filariasis, and leishmaniasis—diseases caused by infestation of tiny parasites in the blood or tissue.

The Public Health Service's New Clinical Center for Medical Research

50 Years' Experience Focused on Chronic Ills

The experience of more than half a century of laboratory and clinical research by the Public Health Service is being brought into focus by the development of the Service's new clinical center for medical research, Norman H. Topping, M.D., Assistant Surgeon General and associate director of the National Institutes of Health, told the 101st Scientific Assembly of the American Medical Association in Chicago on June 9, 1952.

Now nearing completion and scheduled for admission of patients next April, the Clinical Center is a 500-bed hospital with a space ratio of about 2 to 1 in favor of laboratory and research facilities. The Congress, by unanimous vote, authorized the center in 1947.

Changing Research Concepts

Dr. Topping characterized the inter-relationships between clinical medicine and medical research as one of the most intriguing chapters in the history of medicine. "They have never been separated," he said, "but the ways in which they have

Shown above is the Clinical Center now under construction on the grounds of the National Institutes of Health, Public Health Service, at Bethesda, Md., a suburb of Washington, D. C. This view shows the rear (southern) facade of the 500-bed research hospital scheduled to begin operation in April 1953. To the left are service buildings. To the right are two of the present laboratory buildings of the National Institutes of Health.

The center will provide the usual resources of a modern general hospital, including ancillary services such as physical medicine and rehabilitation, medical and psychiatric social work, recreational therapy, and spiritual ministry. Instead of the usual out-patient department, a follow-up service will work with returning patients and carry out special studies involving examination of normal controls, ambulatory patients, and similar functions directly related to the research program.

affected each other, the interest of the laboratory man in clinical problems, and the interest of the clinician in investigation have differed quite markedly as medicine has evolved in this country."

Few people would claim that clinical medicine and research are now related in an ideal way, Dr. Topping observed. "Within the laboratory,"

2:1 Research-Patient Care Ratio in 500-Bed Unit

he said, "specialization has proceeded to the point where the synthesis of ideas across the boundaries of limited fields is becoming difficult. At the same time, the observations and investigations of clinicians are sometimes deficient because the basic requirements of sound research are not or cannot be observed."

"Laboratory and clinical research is no longer the relatively simple combination of a scientist with the itch to solve a problem, plus a couple of dieners, a few animals, chemicals, test tubes, microscopes, and bunsen burners," Dr. Topping remarked, pointing out that more often in research projects today the principal investigator must have the continuous help of a pathologist, a biochemist, a pharmacologist, and perhaps even statisticians and physicists.

The collective judgment of several specialists—both clinical and laboratory—often is needed to formulate reasonable hypotheses, design experiments, and interpret findings. Dr. Topping noted that in addition,

Continued on page 822.

Selection and Study

. . . outline of a hypothetical clinical laboratory investigation of hypertension

To point up more clearly the patient selection and study procedures expected to apply in the new Public Health Service Clinical Center for medical research, Dr. Topping described a hypothetical study to his AMA listeners.

"Let us assume," he said, "that the research staff of the National Heart Institute decides to undertake a long-term study of hypertension with two main objectives: to determine the fundamental causes of this state, and to find better therapeutic agents or procedures.

"A study like this would require regular treatment and observation of the individual over a period of several years. Patients would therefore be selected from stabilized families residing in nearby areas of Maryland, Virginia, and the District of Columbia. The criterion set by the principal investigator might be that of active males between ages 30 and 40, normal in every way except for early symptoms of hypertension.

"Letters describing the study and the admission criteria would be written to the deans of medical schools, hospital directors, and individual cardiologists," Dr. Topping explained. "In this way perhaps 50 patients would become participants in the study, with their first admissions to the center staggered over a 6-month period. At first admission each patient would receive a very complete diagnostic work-up. Thereafter at regular intervals, perhaps every 6 months, patients would be readmitted for observation or therapy. This might occur on a Friday night with discharge on Sunday night, so as not to interfere with the patient's normal work routine.

"Half of these patients might receive one of the new drugs, such as veratrum alkaloids, which have the capacity to lower blood pressure

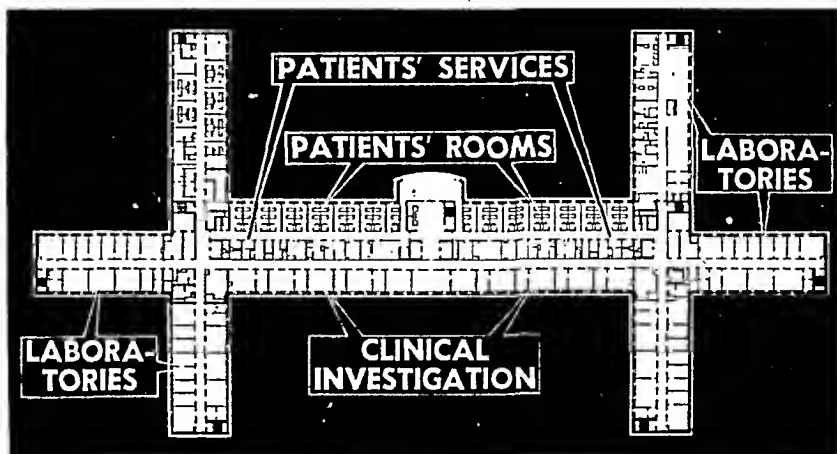

without reducing cardiac output. The other half might be treated also with a sound and practical form of psychotherapy—also believed to reduce blood pressure. Long-term results of the two regimens would be observed and compared.

"The psychiatric studies and treatment would be given through arrangements with the National Institute of Mental Health," the associate director of NIH said. "Regular psychiatric and psychological examinations would also be given to all patients as part of the study of the natural history of hypertension. Clues might thus be obtained to the old problem of which came first: hypertensive disease or the hypertensive personality? Conceivably, one might try to define the basic hypertensive personality and attempt by therapy to modify it. It should also be possible by these means to detect and evaluate the general physiological impact of serious emotional disturbance.

"Similar collaborative studies might be arranged with the Arthritis and Metabolic Diseases Institute in order to obtain information on the interrelationships between metabolic patterns, obesity, hypertension, and psychological states," he noted.

Dr. Topping concluded his description of this hypothetical study by pointing out that "in all studies full reports on each patient will be given at suitable intervals to the referring physician or institution, and the receipt of similar pertinent reports will be welcomed. Active collaboration between the patient's own physician and the Clinical Center staff will be essential for interim therapy and observation. Referring physicians will be welcome to the center and to confer with the appropriate staff members and consultants."

Typical Floor Plan of Clinical Center

Arrangement of a Laboratory Wing

(National Heart Institute)

Juxtaposition of Clinical and Laboratory Areas

Details of the Physical Plant →

This building is a set of laboratories wrapped around a 500-bed hospital. The patients will be located on the south side, usually with 13 two-bed wards in each nursing unit and with two nursing units on each typical floor—one on either side of a solarium.

On the north side, immediately adjacent to the patient area, are the clinical research laboratories concerned with the investigation of problems directly related to the patients.

Between the patients' rooms and the clinical investigation area is a central bank in which various patient services are located, including a kitchen on each floor and a dining room for ambulatory patients.

Basic science laboratories are situated in the six wings. Here the fundamental work in each of the major programs will be conducted. Corridors are arranged so as to separate completely the traffic involved in research activities from patients and the patient-care staff.

There will be a chapel, auditorium, post office, bank, cafeteria, and other facilities for the convenience of patients, whose average stay is expected to be considerably longer than in most hospitals.

The 500 beds have been allocated tentatively among the National Institutes as follows: Heart, 104 beds; Cancer, 126 beds; Mental Health, 98 beds; Arthritis and Metabolic Diseases, 78 beds; Neurology and Blindness, 42 beds; Microbiology, 52 beds.

An entire laboratory wing has been specially designed and equipped for research and therapy utilizing various forms of radiation.

Continued from page 819.

expensive and complicated equipment may be required, citing the mass spectrometer and the electron microscope as examples of equipment which require other especially trained workers to operate and to interpret the findings.

"One of the major challenges of medicine in the years ahead will be to work out the mechanisms, viewpoints, and relationships that will permit the abundant clinical and laboratory talent of the Nation to work most productively for the welfare of man," Dr. Topping maintained. The Public Health Service "looks forward to continued, active participation in this effort," he said.

Selection of Research Problems

Selection of problems for study will be guided, Dr. Topping declared, by a principle long observed at NIH. This "holds that scientific research flourishes and is productive only in an atmosphere of intellectual freedom. Therefore, the acceptance or selection of problems for investigation, the design of the experiment, and the methods to be employed are the prerogative of responsible staff scientists free from pressure, authoritarian direction, or control from above or outside.

"In addition to basic studies in clinical medicine, much of the clinical work at the center will be for the purpose of obtaining clinical evaluation of findings emerging from fundamental laboratory investigation," he said. Other clinical studies undoubtedly will attempt to validate promising new procedures involving small numbers of patients treated elsewhere.

Dr. Topping went on to say that research in fields other than medicine and biology is contemplated under the plan. These would include such subjects as more effective techniques of hospital administration; maximum utilization of subprofessional nursing and physical therapy skills; refined techniques in varied

fields, such as sanitary engineering, safe disposal of radioactive wastes, food and garbage disposal, and similar problems.

Dr. Topping, continuing, pointed out that each research patient will be given as good medical care as he would receive in the Nation's best general hospitals. The details of patient care procedures, the physical arrangements, numbers and kinds of physicians, nurses and technicians, and the facilities at their disposal have been worked out with this goal in mind.

Research History of PHS

Dr. Topping traced the experience of the Public Health Service in laboratory and clinical research "in the modern sense" from its beginnings in 1887 when Dr. Joseph J. Kinyoun established one of this Nation's first bacteriological laboratories.

He noted major contributions of PHS scientists in the diagnosis, treatment, or prevention of such diseases as yellow fever, pellagra, tularemia, hookworm disease, St. Louis encephalitis, dental caries, liver cirrhosis, atypical pneumonia, epidemic conjunctivitis, Rocky Mountain spotted fever, trichinosis, Q fever, brucellosis, malaria, and typhus.

With the years, the Service has been given more and more research assignments. In 1937 the Congress gave official cognizance to public and professional interest in chronic disease when it created within the Public Health Service a National Cancer Institute. This interest continued after World War II, which—as Dr. Topping pointed out—"while temporarily delaying further expansion of basic medical research, proved that fundamental research not only in nuclear energy and electronics but in the medical and biological sciences as well, paid enormous dividends."

In addition to research in its own laboratories—which have expanded substantially since the war as the result of Congressional action—the

PHS, as the agent of the people through the Congress, is now supporting a substantial volume of clinical and laboratory research in the universities and medical schools of the Nation, Dr. Topping reported.

Reviewing the mechanism of the research grants program and the crucial role of National Advisory Councils and the study sections (see *Public Health Reports*, June 1952, pp. 596-597), the Assistant Surgeon General said that the Service was "fully conscious of the heavy responsibility which has been placed upon us to administer these funds in a way that will preserve and enhance the freedom of the investigator and his institution, which is a cornerstone of scientific progress."

Basis of the Center

In the early days of PHS medical research, the associate director of NIH recalled, "the laboratory served mainly as an adjunct to observations and analyses made at the bedside of sick people. In more recent years, when we began also to study cancer, cardiovascular diseases and other long-term illnesses, the state of knowledge was such that extensive fundamental laboratory study was emphasized. It soon became apparent, however, that clinical facilities also would be needed."

Thus, Dr. Topping reported, the Surgeon General appointed a committee to study the question. One of the first conclusions reached by this committee was that a separate research hospital for each class of disease would be wasteful of money and scarce manpower. "Even less desirable would be separation of clinical study into many narrow compartments in the face of a growing realization that different disease entities, different body systems and different fundamental biological phenomena were far more intimately interrelated than had been suspected," he said.

Congressional authorization in 1947 was followed by a year of extensive consultations with clinicians, investigators, hospital administrators, and laboratory designers from other institutions.

"Finally, in 1948, we had evolved a plan which seemed to reconcile the practical with the ideal," Dr. Topping said, "It was a laboratory-hospital building which would allow laboratory investigators and clinicians to work in close physical and intellectual proximity. The main elements of the plan were a physical layout that could encourage free interchange of ideas, plus utility and flexibility to meet the ever-changing requirements of laboratory research, patient care and administrative practices." (For details of the physical plan, see p. 821.)

Use of New Drug As TB Retardant

Streptomycin and isonicotinic acid hydrazide can be used to supplement each other as retardants of germ growth for limited periods during the medical treatment of tuberculosis, Harry J. Corper, M.D., director of research for the National Jewish Hospital at Denver, Colo., told the section on pathology and physiology.

Such retardants are not in themselves cures for tuberculosis, since they have not been demonstrated to destroy the tubercle bacillus in vivo efficiently or within reasonable time, Dr. Corper said in depicting their usefulness as a "notable advance" in research which should encourage the search for more efficient agents to combat the tubercle bacillus.

Although these agents are valuable adjuvants to the regular regimen of tuberculosis therapy, Dr. Corper cautioned against using them if progress is possible without them. He pointed out that the tubercle bacillus is an

exceptional micro-organism among disease-producing germs because it can survive under adverse biological conditions and is able to adapt itself to most antibiotics and chemical therapeutic agents within a relatively short time, both within the body and in a test tube.

Dr. Corper also cautioned against hurried conclusions as to the effectiveness of a drug against the tubercle bacillus because the germ does not readily reveal its intimate protective properties and is able to build up a resistance which lasts for years.

Poliomyelitis Treatment Programs Outlined

The treatment modalities that physical medicine and rehabilitation offer the poliomyelitis patient today are physical agents, therapeutic exercises, and mobilization techniques, Duane A. Schram, M.D., of Gonzales, Tex., told the section on physical medicine and rehabilitation. He remarked that the various treatment programs used throughout the United States are basically similar.

In describing the physical agents, Dr. Schram pointed out that although various types of heat and even drugs have successfully alleviated muscle pain and tenderness in selected cases, consistently good results obtained with the use of moist heat in the form of hot packs have established this method. Recently, the lay-on pack has replaced, to a considerable degree, the conventional wrap-around pack. Hydrotherapy is also used, he added, but generally only in the subacute stage, when the patient can be transported.

Daily electrical stimulation of affected muscle groups will, according to certain claims, not only prevent atrophy but also augment exercises in re-education and strengthening, Dr. Schram continued. The use of a variable frequency generator,

which permits the finding of the optimal frequency in which to stimulate any given muscle group, is a recent development in this technique.

Rehabilitation Techniques

Early in the postacute period an attempt is made to elicit active voluntary control in the affected neuromuscular units, Dr. Schram stated. Advocated techniques include synkinetic movements and positional and stretch reflexes. Regardless of claims for particular types of stimuli, Dr. Schram noted, the problem is primarily one of establishing a situation in which an undistracted, co-operative patient is treated by a skilled therapist using the type of stimuli necessary to accomplish the desired result.

Although a patient may gain some degree of strength on a muscle re-education program, Dr. Schram maintained that more efficient methods can be used after coordination is well established. By using apparatus in exercise, it is possible to record and control the resistive forces used. When the gains in strength begin to diminish, the exercise is gradually changed to one of function; the patient is taught self-help and practical activities with whatever available residual strength he has left.

Mobilization Techniques

Mobilization techniques represent an attempt to attain or maintain normal body alignment, Dr. Schram said. Early in the course of the disease, passive motion is administered to maintain joint mobility and if there should be a mild contracture of a segment, active stretching is indicated. If the contracture or tightness is more than mild, apparatus is often used. Dr. Schram stressed the fact that the apparatus must fit perfectly and that the tolerance of the patient to traction should be guided by the resistance

of the soft tissue to pressure and the adaptability of the patient to the program. The length of time in traction is gradually increased to whatever regimen is required for adequate results.

In conclusion, Dr. Schram emphasized the necessity for all these modalities of treatment to be prescribed with judgment and executed with dexterity. Frequent evaluation is also necessary to emphasize the treatment measures of choice as the patient proceeds in the over-all program.

ACTH and Cortisone In Clinical Medicine

Completing 3 years of study, Laurence W. Kinsell, M.D., Oakland, Calif., thinks it probable that ACTH and cortisone have a true place in clinical medicine—a place to be more accurately defined in the next several years.

Dr. Kinsell reported to the section on general practice on the studies he and his associates are conducting at the Institute for Metabolic Research, Highland-Alameda County Hospital in Oakland.

As of today, ACTH-cortisone may be safely used to return a large number of chronic disease invalids to full activity, according to Dr. Kinsell. Particularly does this apply, he believes, to patients with rheumatoid arthritis and bronchial asthma. Most of these patients, however, will still need many years of continuous hormonal therapy.

"Despite the lack of true curative effect of the hormones," Dr. Kinsell observed, "administration of a sufficient amount to patients with rheumatoid arthritis and with bronchial asthma will result in complete disappearance of all signs and symptoms of the disease in almost 100 percent of the patients. If dosage is maintained at a sufficient level,

the remission will be maintained indefinitely."

Ideal Therapy

This procedure has been followed at the Institute for Metabolic Research, he reported. Although admitting that the "ideal therapy in any disease state is treatment which will totally eradicate the causative agent," Dr. Kinsell and his co-workers have found ACTH-cortisone therapy preferable to the "super-aspirin" approach.

Dr. Kinsell remarked that before the advent of ACTH-cortisone many able and conservative rheumatologists considered aspirin the most valuable single pharmacological agent.

Any treatment presently available for both rheumatoid arthritis and severe nonspecific bronchial asthma, Dr. Kinsell said, is less than ideal because the precise development of the diseases is poorly understood.

Among the patients treated in the ACTH-cortisone studies is a group with diseases for which the mortality rate is high, Dr. Kinsell reported. Their "almost certainly fatal outcome appears to have been postponed indefinitely," he said. One of these had been ill with pemphigus for approximately a year before receiving ACTH-cortisone therapy. Therapy was discontinued 2 years after commencement. No signs or symptoms of the disease have recurred.

Dr. Kinsell discussed another group of studies in which ACTH-cortisone was given to patients with severe infections who had failed to respond to antibiotic therapy. Their improvement was striking.

"It is mandatory," Dr. Kinsell emphasized, "that all patients with infectious diseases, receiving ACTH and cortisone, shall also receive intensive antibiotic therapy prior to, during, and following the hormonal therapy."

Dr. Kinsell added that there were measures to be considered in preventing the "untoward" effects of

ACTH-cortisone therapy. One of these is a dietary program, high in protein and potassium and low in sodium and carbohydrate.

Mass Chest Surveys Urged in Industry

Industry provides an excellent setting for mass chest X-ray screening programs, O. Merton Derryberry, M.D., director of health, Tennessee Valley Authority, Chattanooga, Tenn., stated before the section on preventive and industrial medicine and public health.

He pointed out that the long-term relation between the employee and his plant health service affords opportunity for carrying out the pre-survey and follow-up activities necessary for an effective mass screening program. A high percentage of participation can be obtained; suspect, positive, or indeterminate findings can be followed up conveniently, effectively, and economically; there is reasonable assurance that treatment will be received since both medical guidance and the assistance of employee welfare associations are available; and opportunities for rehabilitation can be worked out.

Dr. Derryberry suggests that, in view of these advantages, industry may prove to be a valuable testing ground for the newer technique, the multiple screening survey.

TVA Survey Cited

To demonstrate the industrial aspects of mass X-ray screening surveys, Dr. Derryberry cited results of the surveys conducted among Tennessee Valley Authority employees. From 1943 through 1949, these surveys were organized and conducted and the follow-up initiated by TVA personnel. From 1950 through 1952, mobile units of official health agen-

cles made the X-ray examinations, but TVA personnel continued the presurvey and follow-up activities.

A total of 76,358 films were made by the TVA unit from 1944 through 1949, Dr. Derryberry reported. Employee participation ranged from 71 to 90 percent. Films read as abnormal ranged from 1.3 to 6.2 percent, the lower percentage occurring with the use of stereoscopic 70-mm. film, which replaced the 35-mm. stereoscopic photofluorograms in 1948. Films read as showing reinfection tuberculosis ranged from 0.6 to 3.5 percent. Other chest abnormalities were found in from 0.6 to 3.4 percent of the films.

The results of the surveys using the official health agency equipment approximated closely those obtained with TVA equipment. "There is no doubt, however," Dr. Derryberry said, "that lessons learned from development and execution of a complete and self-contained TVA chest screening service over a period of several years facilitated TVA's effectively using the results of mass screening provided by the official health agency."

Mobile Unit Planned

The effective application of mass chest X-ray screening led to consideration of multiple screening as a tool of preventive medicine, Dr. Derryberry continued. During the past year, a pilot study at one TVA project produced out of 651 employees screened, 320 who had abnormal health conditions for which corrective action was advised. Plans are now under way to adopt the technique to use in a mobile unit which will visit some 60 scattered locations where approximately 5,000 employees are located, and also to organize similar services at one or more permanent locations.

Industrial medical services, Dr. Derryberry concluded, are strategically placed in the relationship between employee and the practicing

physician and can play a leading role in the progression from case finding, through diagnosis, follow-up, and treatment, to rehabilitation.

The Physician's Use Of Psychotherapy

Physicians need not be psychiatrists to apply psychotherapy to psychosomatic disorders in the opinion of Bernard I. Lewis, M.D., department of internal medicine at the State University of Iowa, College of Medicine, Iowa City, Iowa.

"Patients cannot but benefit when their total illness is competently treated," Dr. Lewis told the section on internal medicine.

"There is no substitute for a valid diagnosis," Dr. Lewis declared. "The basic requirements for a positive psychosomatic diagnosis demand that the manifestations of the particular illness should be characterized by an onset, sequence, nature, and course which suggest disturbed psychophysiological function. The physical and laboratory findings should disclose no pertinent structural lesions or organic disease . . ."

Data From Histories

When this is true, Dr. Lewis suggests looking for the stressful life situation or internal conflict which is currently providing the patient with significant difficulty. The impact of this stress should eventually be correlated with the onset and perpetuation of the present illness. The patient's response to this situation should reflect, physiologically, his unresolved dilemma, or partial but unsatisfactory solution of the problem.

In pointing to a method for obtaining necessary information to satisfy diagnostic requirements, Dr. Lewis reported he had found the standard history and physical examination routine satisfactory. The

routine, however, should be "modified elastically," he added, "to suit the individual patient and bolstered by a few concepts borrowed from our psychiatric colleagues. As emotional disorders are usually reflected in many spheres of activity, important information may be garnered from a survey of the patient's social and vocational history, family relationships, and marital adjustment."

Dr. Lewis emphasized the point that the physician's attitude is all-important in gaining this information. He described the art of observant listening and indirect control of the patient interview as far more valuable than a barrage of leading questions. "The physician's receptive and noncritical attitude plays the vital role in encouraging the patient to divulge facts and feelings of the past which may have important bearings on the present," he commented. "By the use of subtle indirection, an amazing mass of material may be obtained within the framework of the orthodox medical history and within a relatively short period of time."

The Physical Examination

The physical examination will provide the opportunity to detect any objective evidences of such significant emotional dysfunctions as fluctuating changes in skin color, temperature and moisture, vasomotor lability with fluctuating heart rate and blood pressure. "Gross inspection will commonly detect general patterns of significance such as excessive anxiety, tension, depression, or an inappropriate pseudo-calmness," he said.

At this point, with complete knowledge of the patient—his past history, characteristic reaction patterns, and current life situation—Dr. Lewis said that the physician is ready to delineate the genesis of the present illness, its underlying purpose, and its more superficial meaning to the patient.

Subsequent therapy can now be planned, he said. The physician may decide whether his diagnosis calls for immediate psychiatric referral or whether he can undertake therapy himself, he said in emphasizing that the keystone of the therapeutic process is the doctor-patient relationship.

Dr. Lewis believes that the non-psychiatrist can undertake the "suppressive or covering" form of psychotherapy. More superficial than therapy which requires skilled personnel and specialized methods, suppressive therapy can be very effective, he stated. It functions in two areas: manipulation of the patient and manipulation of his environment. Dr. Lewis concluded:

"Superficial insight into the relationship between his emotional problems and physical symptoms with appropriate, simplified explanation of the underlying mechanisms will give the patient additional understanding and frequently dissipate many of his fears. When he appreciates that these disorders are extremely common—that everyone has a tolerance level beyond which he will break—the patient will no longer regard himself as a defective specimen and will tend to regain his self-esteem. In conjunction with these direct efforts, it is often necessary to effect certain environmental changes so as to minimize the stressful factors impinging upon the patient. For this purpose, the relatives or employers should be consulted and their cooperation secured. Similarly, the services of various social agencies should be utilized."

State Health Services Dispersal Continues

In the past decade, dispersion of health functions throughout the structure of State government has gone on apace. Jack C. Haldeman, M.D., chief of the PHS Division of

State Grants, told the section on preventive and industrial medicine and public health at the Chicago AMA meeting on June 12.

Reading a paper largely prepared by the late Dr. Joseph W. Mountin, he said that the current study reveals: "First, a maze of official agencies in each State, with wide scattering of responsibilities for health programs throughout the maze; second, a State-to-State difference in the configuration of agencies responsible for specific functions; third, State-to-State variation as to degree of responsibility for those functions."

The data presented were based on the 1940 and 1950 decennial surveys of State health organizations made by the Public Health Service. "The interest of the American Medical Association may be assumed," Dr. Haldeman noted, "since the first comprehensive survey of State health departments was made under the auspices of your association, by Dr. Charles V. Chapin in 1915."

60 Types of Agencies

For the Nation as a whole, exclusive of organizations differing in name only, there are 60 distinct types of State agencies carrying health functions, Dr. Haldeman reported. In 1940 there were 48 types. The maximum number in any one State in 1940 was 18; today it is 32.

Attempts at integration are, however, being made, Dr. Haldeman said. He mentioned water pollution control, school health services, and tuberculosis sanatorium direction as examples.

Dr. Haldeman believes that "the steady extension of interest in health matters reflects not only general public enlightenment but also the decade's advances in scientific knowledge and resources. Moreover, medical advances have simplified or eliminated many of the earlier public health problems—leaving elbowroom for State health and other agencies

to branch out into new fields and ideas."

State Activity Progressive

"From this standpoint," he continued, "State health activity is progressive. More than half of the programs in the current survey are carried on in all the States and Territories by at least one official State agency. This degree of responsibility among the States did not exist in 1940, when less than one-third of the programs were carried out in each of the States. Today, the only activities in which fewer than three-fourths of the States participate are some of the newly established chronic disease programs, hygiene of housing, human blood and blood derivative programs, and health services for migratory labor."

Some progress has been made in concentrating the older and better established programs within health departments, Dr. Haldeman reported. "Nevertheless, our findings indicate that too many areas have failed to utilize—especially for the more recent programs—the extensive authority, the technical skills, and the basic interest in total health available in the health department. Organizationally speaking, the new functions appear to have been fitted into or tacked onto the administrative framework of State government without system or design."

Health Expenditures \$1 Billion

Turning to fiscal aspects, Dr. Haldeman reported total health expenditures for preventive services, hospitalization, and medical care provided by the 48 States in 1950 as approximating one billion dollars—about three times the 1940 level of expenditures.

"Of the current total," he reported, "74 percent was State appropriated; 15 percent was derived from Federal grants—of which more than half was for the school lunch program; 1 percent was furnished by local gov-

ernments; and 10 percent came from other sources."

The total per capita figure was \$6.30, ranging from \$3.26 to \$13.58. State health departments are responsible for only one-sixth of the aggregate expenditure. Welfare departments account for another one-fifth; educational authorities, for one-tenth. About 55 percent are for hospital expenditures, usually not the responsibility of State health departments, Dr. Haldeman noted.

"In the fiscal year 1949, the 48 State health departments spent nearly \$160,000,000," he reported. State-appropriated funds amounted to more than two-thirds of this total. A decade ago this proportion was less than three-fifths.

Local Initiative Growing

"This contradicts," Dr. Haldeman felt, "the claim sometimes made that Federal aid dries up local initiative. During the 10-year period, total per capita expenditures by State health departments increased by more than 200 percent, while the increase for the median State amounted to 183 percent." He noted that about half of the increase reflected rising prices, but "the remaining half reflects, to a considerable extent, true expansion of program."

The reports indicate an increasing delegation of health activities and funds to local areas, Dr. Haldeman commented. "To me, this is clear-cut evidence of the dynamic quality of Federal-State, State-local relationships."

State health personnel of all types have increased by two-thirds during the decade—from 16,000 to 26,000 full-time personnel. The majority are State health department employees. Dr. Haldeman noted advances, plus wider disparity in operation, of merit system units. He also commented on the tendency of salaries to fall behind cost-of-living advances.

Training of public health workers has now become an important part

of State health work, Dr. Haldeman reported. Some types of training are now offered in 49 of the 53 State and Territorial jurisdictions. In 1950, some 11,000 persons received training offered by State health departments, as compared with about 850 in 1940.

Orientation Too Narrow

In concluding the paper for himself and Dr. Mountin, Dr. Haldeman declared:

"It is difficult to escape the conclusion that the desire for health is a compelling urge in American life, but as yet insufficient leadership has emerged around which the separate forces will rally. Possibly the strength of the movement lies in its many sources of origin. Possibly it is too early to channelize this tide, the depth and breadth of which cannot be measured. We of traditional public health and medical background naturally had hoped that the State health department might be the coordinating, if not the integrating, mechanism in the States. But I fear its current orientation is too narrow.

"That which was presented in 1940 as a plea must now be regarded in stronger terms," Dr. Haldeman continued. "Today it is even more imperative that maximum efficiency of organization and cohesive action be obtained, if full advantage of all the technical developments currently at our command is to be realized. No matter from whose viewpoint the issue of overlapping health services is approached—from that of the economist, the business man, the administrator, the physician, or the consumer—there is little to recommend it."

Step Up Program of TB Case Finding

Although the disease is still the leading cause of death among the

group 17 to 37 years of age, Arthur C. Christie, M.D., of Washington, D. C., told the military medicine section, mortality from tuberculosis has fallen to 33,557 in 1950 from 200,000 in 1900. Emphasis, he said, should now be shifted from mortality to morbidity as a measure of the prevalence of tuberculosis.

Reporting on a follow-up study of a mass chest X-ray survey in Washington, D. C., Dr. Christie said that only 41 percent of the estimated population was examined, and 35 percent of the cases found were unknown to the health department.

One value of a mass survey, he stated, is that it discloses high-prevalence localities or groups in which screening efforts may be concentrated. The follow-up study showed that one-fourth of those having tuberculosis were age 55 and over although this group was only 10 percent of the population examined. Case finding among the older age group must be intensified, he added.

"Everything," he said, "points to the need for stepping up the program of case finding throughout the Nation and to the need for increased facilities for care of the tuberculous."

Much arduous work remains, Dr. Christie said, but the knowledge accumulated in the Washington survey gives, for the first time, a sound foundation for future planning.

Industrial Employees' Health Programs

Experience obtained in setting up and operating a medical program in the Bureau of Old-Age and Survivors Insurance has shown that the familiar public health techniques can be successfully adapted to industrial medical programs, William T. Doran, Jr., M.D., M.P.H., medical director of the Bureau of Old-Age and Survivors Insurance, Social Security Administration, asserted in his ad-

dress before the section on preventive and industrial medicine and public health.

Before the inception of the program, Dr. Doran said, eight industrial nurses administered on-the-job emergency first aid to employees on the day and night shifts in four separate buildings. Many of the employees had no family physician and did little for their health because of lack of a physician's guidance.

Dr. Doran said that the bureau offered an ideal challenge for the development of such a program because of the nature of its functions, the distribution of its plants, and the character of its personnel.

The specific techniques used in the BOASI program, Dr. Doran said, include participation of employees in planning, surveys of health needs, statistical sampling methods for uncovering health data, sampling to disclose employees' receptiveness to health demonstrations, integration of health activities with those of the local community, health education, follow-up studies, and methods of evaluating the program.

Employee Participation

The important factors in the program outlined by Dr. Doran were

team operation, the individual's personal pride in his health, and the "person-doctor" relationship. Emphasis is placed on preventive measures, he stated.

Dr. Doran said methodology is explained to the employee groups and their reaction is sought. Employees' ideas about health and the diseases in which they are interested, health problems of their occupations, their ideas as to methods of obtaining medical and health care and the health services they desire are submitted voluntarily and anonymously by employees, Dr. Doran stated.

A management-labor-medical guidance program, he continued, consists of three advisory committees: one of top management representatives, a second of employees, and the third an ad hoc group of local physicians. These committees afford technical advice and counsel, assist in the dissemination of information, and promote the program.

Available data gathered for initial use early in the program consist of studies of pre-employment examinations and reports of employee visits to health units, hospitals and clinics, and similar sources.

Dr. Doran reported that the first Baltimore service program, a chest survey, reached 99 percent of the BOASI employees. Films, posters, pamphlets, and information articles on health were used. Mental hygiene round-table discussions utilize group dynamics stimulated by a panel of experts from medicine, psychiatry, psychology, social work, personnel, and management.

Recorded data of medical experience, sickness absenteeism, production, and use of health facilities are compiled and tabulated for evaluation of the program or any of its parts.

Each employee has his own unit medical record folder with all data concerning his health experiences, Dr. Doran reported. Punch cards are maintained on the individual's health characteristics to indicate the employee's participation in the projects and lay the groundwork for follow-up study as to the effectiveness of the various programs. Follow-up care of persons found to have tuberculosis, cancer, or other conditions is provided by referral to the individual's private physician, or to city and State facilities, with contact maintained by nurses and social workers from BOASI.

Tabulations of Birth Weight Statistics

A guide for States to follow in gathering prematurity and neonatal mortality data will be found in "Suggested Tabulations of Statistics on Birth Weight and Related Characteristics for Live Birth and Neonatal Deaths." The tabulations are based on data derived from matched birth and infant death certificates and supplement "Recommendations for Developing Comparable Statistics on Prematurely Born Infants and Neonatal Mortality," which was published in 1950.

The original publication and its supplement were issued jointly by: the Public Health Conference on Records and Statistics; the Association of Maternal and Child Health and Crippled Children Directors; and the Children's Bureau and the National Office of Vital Statistics, Public Health Service, Federal Security Agency.

The Health Department and Nursing Homes

By MARGARET RANCK, R.N., and R. R. CUNNINGHAM, B.S.

The number of nursing homes in the United States has increased with the number of older people in the population. Because of many factors in family life and in our culture, these homes have come to provide care for the aged, the chronically ill, and the convalescent patient. Since the problems involved in the care of these older people probably differ little from State to State, the experience of Illinois in dealing with them may be of general interest.

In Illinois, popular concern about nursing homes and their growth became so great by 1945 that an organized drive developed for a licensing program. Through legislation enacted that year, the Illinois Department of Public Health became responsible for the licensing and supervision of nursing homes. The objective in licensing is to assure good personal care in a pleasant, safe environment where individual dignity is respected and recognized.

Under this law, any establishment housing three or more persons who "by reason of illness or physical infirmity are unable properly to care for themselves," must be licensed on the basis of minimum standards of sanitation, hygiene, diet, and number and type of personnel. The State Department of Public Health is responsible for establishing minimum standards for licensure.

Proprietary and nonprofit homes, including those for the aged that provide infirmary care, are licensed under the Nursing-Home Act.

Miss Ranck is consultant nurse and Mr. Cunningham is sanitary engineer with the bureau of hospitals of the Illinois Department of Public Health.

Nursing units of a general hospital which are principally for the care of the chronically ill, nursing homes operated by Federal and State governmental units, and private mental institutions and rest homes (licensed by the State Department of Welfare under provisions of the Illinois Mental Health Act) are specifically excluded. Homes in municipalities having local provisions for licensing comparable to those of the State law are also excluded. At present, these include the cities of Chicago, Evanston, East St. Louis, Rockford, and Springfield.

Administration of the Program

Since many of the requirements of the Nursing-Home Act involve sanitation and building, its administration was first delegated to the State health department's division of sanitary engineering. After 4 years' experience in administering the act, program emphasis had changed to considering the service to residents in the building as of prime importance. The job of administration was transferred to the bureau of hospitals of the division of hospitals and chronic illness in July 1949.

The bureau staff assigned directly to the administration of the licensure program includes a sanitary engineer, two registered nurses, two stenographers, and a clerk. The services of other specialized personnel are available for consultation. Although the statute places the responsibility for the administration of the program on a State level, it has been the policy of the small, central staff to serve in a consultant capacity. Much of its direct counseling service is provided through a cooperative arrangement with regional, county, and city

health departments. Thus, the staff's counseling service is available to the entire State, and the organized local health departments are strengthened.

These local health departments, familiar with conditions in their communities, evaluate proposed homes, interview prospective operators, make visits, and investigate complaints. Their reports and recommendations, made verbally to the home management, are submitted to the bureau of hospitals for forwarding to nursing homes concerned. It is the policy of the bureau to uphold local health department recommendations.

When the manager of a home inquires about licensing, he is asked to submit a preliminary application blank containing information concerned with administrative ability. References are queried. If replies are satisfactory, the local health department is asked to inquire further into executive aptitude, survey the building, and give advice and make recommendations regarding staff, program, building, and equipment.

The home management is always entitled to a hearing under the law. Management frequently requests an opportunity to discuss new construction and remodeling, assistance with organizational structure, nursing care, and many other problems. Legally the department does not revoke or refuse a license without fair hearing before the director of the department. This procedure has rarely been necessary because educational measures are used to help the homes meet the standards.

The Nursing-Home Act provides that the homes must be inspected and approved by the office of the State Fire Marshal as well as supervised by the State Department of Public Health. No nursing home is licensed in Illinois without written approval from the division of fire prevention of the Department of Public Safety, certifying that the home is satisfactorily protected against fire hazards.

Many Illinois cities and counties have either passed or are considering zoning ordinances which would regulate the types of buildings, their uses, and locations within corporate limits. So that there will be no violation of local zoning ordinances, a license is not issued to a nursing home until a permit to use the location

is received from local governmental authorities.

Health Team Responsibilities

The activities of the various professions on the health team concerned with nursing home visitation and counseling are basically complementary. Major responsibilities are fairly well defined.

Public Health Nurse

The public health nurse is concerned primarily with the adequacy and competency of the nursing home staff. She observes the ability of the operator to conduct an efficient business, notes the physical and apparent emotional health of the staff, and inquires as to their living and working arrangements. She also notes the medical attention given residents, and observes whether or not physicians' orders are written, whether adequate medical and nursing records are being utilized, whether there is proper storage and accounting of drugs and prescriptions, and whether proper policies are being employed in admitting and discharging residents. She is concerned also with comfortable furnishings and nursing care equipment.

In addition, the nurse evaluates nursing procedures and treatment techniques. She checks the personal hygiene of the residents. She is concerned with policies about the use of the telephone, visiting hours, and mail censorship. She notes whether a resident of a multipatient room has privacy for treatment or during acute illness and whether this privacy extends to interviews with his clergyman, social case worker, and family. She calls attention to new and useful reference materials.

Many other items concern her. The resident's personal property must be properly stored; housekeeping, personal care, and laundry service must assure control of odors; food must be nutritionally adequate, attractive in appearance, and satisfactorily served. There must be some device for signaling an attendant.

The nurse encourages the use of the living room since recreational and occupational therapy are so valuable. Here members may join in activities designed to divert attention from themselves. She encourages residents to

move freely about the home and thus calls attention to the importance of ramps and handrails on porches, stairs, and long hallways, as well as adequate storage space for walkers, crutches, and wheel chairs.

Her job is more difficult because of the need for many more nurses in Illinois homes. A survey made of 317 licensed homes in January 1950 indicates that only a very small percentage of the residents in these homes were receiving the services of a graduate professional nurse (see table).

The Technical Subcommittee on Chronic Hospitals and Nursing Homes of the Committee for the Improvement of Nursing Service of the Illinois State Nurses' Association has established a standard of 21½ hours of nursing care for each patient per day (24 hours); one-sixth of this service is to be provided by professional nurses and five-sixths by nonprofessional or practical nurses. On the basis of the 1950 study, 827 professional and 4,135 practical nurses would be required to meet the standards of the committee. Significantly, only 344 professional and 1,924 practical nurses were employed in Illinois nursing homes at that time. The situation is somewhat improved since that study was made.

Sanitary Engineer

The sanitary engineer is concerned with the layout and facilities of the nursing home's physical plant and with all safety and sanitary measures that tend to promote health. In homes not served by a public water supply and sewerage system, for instance, he advises the operator on the construction, maintenance, and operation of private facilities. Since most Illinois nursing homes are located within the corporate limits of a municipality, the water supply and

sewage disposal facilities seldom create serious problems.

The sanitary engineer surveys all plumbing fixtures in the building from the standpoint of back siphonage and cross connections because of the danger of water contamination. He sees that the building is provided with a sufficient quantity of hot running water, that it is equipped with a central heating plant with at least one outlet in each room, that it has facilities for the proper storage and disposal of garbage and for washing bedpans and other utensils, and that it has the proper number of bathrooms and fixtures. He pays special attention to such safety precautions as width, rise, and tread of stairways, handrails, condition of floors, unnecessary obstructions, and the location of lighting fixtures.

Since the majority of nursing homes operating in Illinois were previously large private dwellings, the engineer often must recommend changes. The size and arrangement of kitchen equipment to allow for sanitary food preparation, storage, and distribution often present problems. Original floor plans commonly permit traffic through patients' rooms, or through the kitchen to bathrooms or laundry. Often the bathrooms or bedrooms open directly into food preparation areas. These also require changes.

The minimum standards for licensure specify that the capacity of the home is dependent upon the number of square feet available in each bedroom area. The engineer, therefore, measures the rooms and prepares sketches which assist the operator to determine room capacity and to make certain that sufficient space is allowed for storage. Such sketches may also indicate the installation of additional windows for lighting and ventilation.

The location of the building has an important

Administrator of nursing service in 317 licensed nursing homes Jan. 1, 1950.

Professional training of administrator	Proprietary homes		Nonprofit homes (endowed, religious, fraternal)	
	Number homes	Number residents	Number homes	Number residents
Registered nurse.....	55	1, 641	18	2, 046

Nonprofessional nurse with experience only.....	183	2, 973	18	1, 077

bearing upon services provided by the sanitary enginners. It should be on a serviceable street with special consideration given to the proximity of industrial plants, highways, railroads, and business establishments. It must be equipped with a telephone to summon physicians, relatives, the fire department, or other services. An adequate, well-drained yard space should be provided so residents can be out-of-doors as much as possible.

Nutritionist, Dietitian, Architect

The nutritionist visits nursing homes according to their recognized needs and desire for help. She gives guidance concerning kitchen planning and arrangement, menu planning, food buying, storage, service, and recipes. She acts as a resource person at group operators' meetings and at health department staff meetings.

The bureau of hospitals urges people who plan to establish, remodel, or enlarge nursing homes to send in their original blueprints for approval prior to actual construction. If these involve facilities for food service, the consultant dietitian gives recommendations on layout and efficient operation, necessary equipment, and the location of food storage facilities.

Since nursing homes in Illinois usually operate on limited funds, plans for alterations or additions are ordinarily drawn up in rough form by a local builder or contractor. While the bureau of hospitals' architect is not permitted to prepare detailed professional drawings and specifications, he does assist in review of the plans.

Occasionally, too, the architect visits the home and discusses with the operator the cost and feasibility of proposed alterations. As a service to operators, contractors, and practicing architects, he has developed a plan for a typical two-bed and four-bed unit, showing the utility room, nurses' station, and bathroom for each sex, in accordance with the needs of infirm residents and the minimum standards for licensure.

Educational Program

Since the owners of most nursing homes have entered a new business with little experience,

the importance of educational programs which develop a greater appreciation of good personal care cannot be overemphasized. As has been pointed out, the bureau of hospitals has distributed educational materials to the homes, some prepared by the State Department of Public Health and others by other health and welfare agencies. These cover such subjects as "Aging," "Menu Suggestions for Nursing Homes," "Food Handling Regulations," "Food Needs as We Grow Older," and "Eating Is Fun for Older People, Too."

In addition, the bureau has cooperated with the Department of Nursing of Loyola University, Chicago, in presenting a series of institutes on nursing care of the older patient. This joint project has proved an excellent means of interesting both students and professional nurses in the field of geriatric nursing. Schools of nursing, too, are beginning to use nursing homes as experience fields for professional and practical nursing students. The bureau encourages the development of such training if it is properly supervised. This experience is valuable not only to the student, but also to the self-respect of the home.

Since the inception of the nursing home program, routine visits and printed literature have not been considered complete answers to the educational needs of nursing home operators. From this feeling grew a series of group meetings. The first, which took place early in 1949, was organized for a discussion of the medical and nursing record forms which the department provides for all nursing homes. Among the topics discussed subsequently were food service problems, various phases of nursing, activity programs, and fire protection.

State-Wide Organization

Interest in a state-wide organization of nursing home operators began to develop as a result of these small meetings, and the Illinois Association of Nursing Homes came into being in March 1950. Its purpose, according to its constitution, is "to promote good standards of care in nursing homes by adherence to a code of ethics among its members . . . and by the development and dissemination of information which will lead to better care of patients and

the solution of problems which are common to the individual members of the Association."

Constituent district nursing home associations, in order to be recognized by the Illinois Association; must include in their constitutions or bylaws the equivalent of the following code of ethics as one of the qualifications for membership:

- Management with integrity and responsibility.
- Service with regard to the total physical, mental, and spiritual needs.
- Staff of good moral character, experience, competency.
- Facilities with provision for safety and adequate care.
- Courtesy to residents, relatives, and the public.
- Cooperation with the community, health, and welfare agencies and with professional personnel.

Of 560 licensed nursing homes in the State on March 15, 1952, 104 are now members of the Illinois Association of Nursing Homes. The membership is small, but it is active and enthusiastic. During its first year of operation it was admitted into the American Association of Nursing Homes, which accepts only associations in States which license homes by statute. Through its education committee the Illinois Association has sponsored three institutes on nursing home management in cooperation with the University of Illinois and the Illinois Department of Public Health. The fourth is scheduled for November 11-14, 1952.

In 1950 the Illinois Association of Nursing Homes cooperated with the Illinois State Nurses' Association and other allied health organizations in promoting legislation to include practical nursing licensure as a part of the Illinois Nurse Practice Act. The nursing home association supported amendments to the Nursing-Home Act. Both these bills were enacted into law in 1952.

In addition to the tangible benefits the homes derive from the organization, there is a growing feeling of solidarity in the association in facing problems common to the whole group, improving public understanding of the nursing home as an essential community service, and developing higher standards than are required by the State for nursing home licensure.

People and their needs must be the focus of attention. Many residents are in these homes for reasons other than chronic illness. Many

have passed their eighty-fifth birthday, but at least half of them are able to walk without support. They need companionship and friendship as well as housing, nursing, and maid service. They may require some supervision and direction. They need outlets to develop skills which give satisfaction.

Health department personnel, then, must be more than inspectors. They must be good teachers. They must assist the owners and superintendents of homes in reaching a higher level of operation than the lowest standard the State will accept for licensure. To do this in Illinois, counseling and visitation must be increased and more institutes conducted by the Illinois Association of Nursing Homes in cooperation with the colleges and universities.

Moreover, a great deal might be accomplished by adding a group worker, trained and experienced in social work techniques, to the existing consultant staff to assist management to develop programs in the homes designed to retard mental and emotional deterioration of the individual. Practical nursing education should be promoted in accordance with the recommendations of the National Association for Practical Nurse Education and in accordance with the practical nurse aspects of the Illinois Nursing Act. Continued assistance should be given to the Illinois Association of Nursing Homes in developing and improving records, simple accounting forms, nursing procedures, and general policies for use by the homes. Assistance is being given in the development of a nursing home administration manual.

The bureau of hospitals should continue to work with superintendents of homes for the aged and representatives of medical, nursing, and dental groups in developing a cumulative health record for the apparently well resident. It should also assist them in developing plans for regular preventive service. It is hoped that a state-wide association of homes for the aged will be organized and that it will give guidance to the Illinois Department of Public Health in the development of educational materials for the operation of such nonprofit homes.

Conclusions

In Illinois, as throughout the Nation, the general public is not always aware of the costs

of operating satisfactory homes. Nonprofit homes, praiseworthy as they are, have difficulty acquiring funds for improvements, expansion, or the building of new plants. Commercial nursing homes have no subsidy. For improvements and expansion they have only the profits made from caring for residents after expenses have been deducted. Obviously, minimum standards will have to remain low until these homes are remunerated so they can provide better care. Social case-work services, physiotherapy and occupational therapy, and more recreation and diversion services are badly needed in many homes.

With mounting costs of equipment, labor, food, utilities, and taxes, the commercial nursing homes may be forced to discontinue service to those persons dependent on public funds for their care. Illinois is comparatively generous in paying for this care, yet there is great pressure on the licensing agency to abolish living rooms in the homes and to permit crowding of residents so that the commercial home may operate without a deficit. Standards for additional services could be written now, but it is doubtful if they could be enforced until much more education, for boards of directors, owners, and staff, has promoted a readiness to proceed another step upward.

A study of nursing home laws and regulations in various States reveals a startling need for some type of standardization. A nation-wide committee has been appointed to draft a statement of standards. The availability of a national manual of desirable as well as minimum standards is to be hoped for.

The 1951 revision of the Illinois Nursing-Home Act provided for a Nursing Home Advisory Council composed of two representatives of the Association of Nursing Homes and one representative each of the Hospital Association, Medical Society, State Nurses' Association, State Fire Marshal, Public Aid Commission, Municipal League, and the County and Town-

ship Officials' Association. The advisory council has already given helpful service to the bureau of hospitals in the development of revised standards.

A broadly representative national committee is needed. It should be adequately financed so as to have secretarial service and a travel budget for attendance at committee meetings. It should be representative of all sections of the country and of such organizations as the American Public Health Association, National League for Nursing, State and Territorial Health Officers' Association, National Social Welfare Assembly, Council of State Governments, American Municipal Association, National Fire Protection Association, Commission on Chronic Illness, American Public Welfare Association, American Association of Nursing Homes, American Hospital Association, and of other nursing home associations, homes for the aged, community chests, and councils.

Its functions might include development of suggested laws, ordinances, and desirable and minimum standards that would be useful to States, cities, and counties.

The next step in improving conditions in the homes might be the enactment of valid city or county licensing ordinances, administered by full-time local health departments.

Experience in administering the nursing home program in Illinois has indicated the rapidity of the development of this type of service. It has pointed to the need for licensing control in order to assure minimum standards of care and has demonstrated the value of education for better standards of care.

Licensing agencies, local health and welfare departments, and many national organizations, as well as the general public, are beginning to realize the importance of the nursing home as a valuable community facility. With this support, such institutions can provide an increasingly valuable service in the care of the aged, physically infirm, and convalescent citizen.

Morbidity and Mortality Experience Among Chromate Workers

By HUGH P. BRINTON, Ph.D., ELIZABETH S. FRASIER, Litt.B.,
and A. LINK KOVEN, M.D.

The abnormally high rate for cancer of the respiratory system among workers in the chromate-producing industry was demonstrated by Machle and Gregorius (1) in 1948. At that time, so far as was known, nothing on morbidity experience and little on other causes of death among chromate workers had been published. The present report on morbidity and mortality among male workers in the seven chromate-producing plants in the United States is offered because of the increasing interest in problems related to specific health hazards in this industry.

In 1950-51, the Public Health Service made an engineering study of the working environment in all seven plants and a detailed medical study of workers in six of the plants. As part of these studies, data were collected on paid death claims and on claims for sickness and nonindustrial injuries disabling for eight calendar days or longer among members of sick-benefit plans. This morbidity and mortality report thus covers all workers who are members of

sick-benefit plans in the seven plants in the United States engaged in the extraction of chromates from chemical-grade chromite ore. These plants are located in Maryland, New Jersey, New York, and Ohio. Periods for which accurate sickness and death records were available varied from 2 to 11 years. The rules and regulations of the sick-benefit plans may be summarized as follows:

In all of the plants, benefits began on the eighth day of disability. Prior to 1949 the maximum period for which benefits were paid was 13 weeks. With the passage of a sickness insurance law in New Jersey, effective on January 1, 1949, plants located in that State had maximum benefits extended to 26 weeks. However, in order that the data for all companies be comparable, cases of disability lasting longer than 98 days were arbitrarily closed at 98 days. The calendar days of disability, therefore, are defined as the number of calendar days from the date of onset of disability to the date of return to work or to the ninety-eighth day, inclusive, except when the employee died or was pensioned before the ninety-eighth day.

Before 1949 the probationary or waiting period between employment and eligibility for membership in the sickness insurance plan was 6 months for two plants, 3 months for one plant, and 1 month for three plants; one plant had no plan. After the New Jersey State sickness insurance law went into effect in January 1949 and a New York law became effective on July 1, 1950, workers in the plants in these areas were eligible for benefits as soon as they were employed. By the end of 1950, one plant still had a waiting period of 6 months, one plant had a waiting period of 1 month, and the remaining five plants, located in New York and New Jersey, had no probationary periods.

At first, membership in the sickness insurance plans was voluntary in all plants, but after the enactment of the New Jersey and New York laws, membership was compulsory for plant workers in those States. In the two plants where membership remained voluntary,

Dr. Brinton and Miss Frasier are with the statistical section of the Division of Occupational Health, Public Health Service; Dr. Koven is with the medical section of that division.

The data presented in this paper were collected in connection with the division's study of health among workers in the chromate-producing industry. A comprehensive report on the health of these workers will be published separately.

coverage was approaching 100 percent of all employees toward the end of the study period.

Although a medical examination was not required before a worker could become a member of a sickness insurance plan, all plants required a medical examination before employment. There were no age limits on eligibility for membership. However, some plants which allowed 26 weeks' benefits for each different disease during a year permitted only a total of 26 weeks per year for all diseases for persons over 60 years of age.

From the foregoing rules and regulations it is evident that the only newly employed workers included in the study were those who entered the New Jersey plants during 1940 and 1950 and the New York plant during the last 6 months of 1950. Neither the morbidity nor the mortality experience of employees during the probationary period (whether they quit or remained with the plant) was included.

The disability analysis is based on only those cases that occurred while a worker was a member of the sickness insurance plan. All disabilities that ended between January 1, 1946, and December 31, 1950, are included, provided that they lasted for 8 calendar days or longer. Hence, disabilities that began in 1945 and ended in 1946 are included. The actual number of days for all cases ending during the study period are counted up to the ninety-eighth day, inclusive. Industrial injuries and compensated cases of occupational disease are not included.

The mortality analysis is based on information from the records of the sick-benefit associations which contained data on death benefits. Only deaths of workers who were members of a sick-benefit association and died within one year after becoming disabled are included. Sudden deaths and deaths before the eighth day of disability are included; although these cases were not eligible for sickness benefits, they were eligible for death benefits. Deaths due to industrial injuries are not included. All deaths were classified by cause as given on the death certificate without additional verification.

Disability Experience, 1946-50

During the 5-year period 1946-50, for the seven chromate plants there was a total of 5,121 person-years of membership in sick-benefit plans, 3,663 for whites and 1,458 for nonwhites. It will be observed from table 1 that the proportion of nonwhites in the total membership

declines rapidly after 55 years of age. In the age group 65 years and over there were 136 white males as compared with 9 nonwhite.

Table 1. Person-years of membership in sick-benefit plans, by age and race

Race	Total	Age, in years				
		15-34	35-44	45-54	55-64	65 and over
All males...	5, 121	1, 497	1, 457	1, 212	810	145
White.....	3, 663	1, 014	1, 015	803	695	136
Nonwhite....	1, 458	483	442	409	115	9

Six of the plants reported during the full 5-year period, with a steady increase in the average membership in sick-benefit plans from 1946 through 1949. The seventh, a small plant, reported only during the last 2 years, 1949 and 1950.

Frequency by Year Case Ended

In 1946, the average annual number of cases of disability on account of sickness and nonindustrial injuries was 130.9 per 1,000 white and 186.2 per 1,000 nonwhite males, compared with 109.8 and 124.6, respectively, in 1950 (table 2). The rates for the broad cause groups are not shown in this table, but an examination of those rates reveals that the abnormally low rate for white males in the chromate industry in 1947 (86.0) is attributable to a marked decrease in respiratory diseases for that year. Nonwhite males also showed a decrease in the respiratory disease rate for 1947, but this was more than counterbalanced by an increase in nonrespiratory-nondigestive diseases. There was a slight upward trend in the rates for nonindustrial injuries, while the rates for digestive diseases and nonrespiratory-nondigestive diseases fluctuated, but not in one particular direction.

Duration According to Broad Cause Group

Disability frequency rates for white and nonwhite males under 55 years of age according to duration of case are presented in table 3 for the broad cause groups. For sickness and non-

Table 2. Frequency of sickness and nonindustrial injuries lasting 8 consecutive days or longer, according to year case ended, by race ¹

Year case ended	Annual number of cases per 1,000 males			Number of cases			Average person-years of membership in sick-benefit plan

nervous system, diseases of heart, other diseases of circulatory system, and diseases of skin.

With regard to race, the number of days of disability per male follows much the same pattern as the frequency rate.

Days per case averaged 35.4 for white males and 33.8 for nonwhite. With the exception of influenza and grippe, other respiratory diseases, diseases of the stomach except cancer, appendicitis, diseases of heart, and diseases of organs of movement except joints, the average days per case for the whites are equal to or greater than those for the nonwhites.

Age and Broad Cause Group

Table 5 shows the effect of age on the frequency of sickness and nonindustrial injuries. For both races the sickness rate tends to increase with advancing age. Among white

males 55 years of age and over, the nonrespiratory-nondigestive disease rate is more than five times that for persons under 35 years. Among nonwhite males the older group has a frequency rate almost four times that of the younger group. Respiratory diseases are much more common among nonwhite males at each age group, but the relative excess was less among persons 55 years of age and over.

Comparative Sickness Experience

In table 6, the sickness experience during 1946-50 for white male chromate workers is compared with a large group of industrial workers (predominantly white). The annual number of cases of sickness per 1,000 males was 107.8 for chromate workers and 96.3 for other industrial workers.

In general, the rates for specific causes of

disability among chromate workers are not greatly different from those found for other industrial workers. However, it will be observed that illness from cancer appears excessive among chromate workers—7.1 compared with 0.7 for workers in other industries. Respiratory diseases are slightly more frequent among chromate workers, the major part of the excess being due to higher rates for influenza and grippe, bronchitis, acute and chronic, and pneumonia. When cancer is omitted the rate

for nonrespiratory-nondigestive diseases is very similar for the two groups, except for a slightly higher heart disease rate among chromate workers.

Disability and Deaths From Cancer

Cancer disability and death data during the 11-year period 1940–50, inclusive, are based on the experience of members of two plants during 1940–50, one plant during 1943–50, three plants

⁴ Exclusive of influenza and grippe, respiratory tuberculosis, and venereal diseases.

during 1946-50, and one plant during 1949-50, which yielded a total of 7,818 person-years of membership in sick-benefit plans, of which 5,502 person-years were for white and 2,316 were for nonwhite males.

Deaths

During the 11-year period there were 44 deaths from cancer occurring within 1 year after the chromate worker had ceased employment because of disability due to cancer. An additional 4 deaths occurred among persons disabled for more than a year. For the former group, table 7 shows the length of terminal sickness according to age and race.

It would appear that half of the white and half of the nonwhite males died in less than 100 days after becoming disabled with cancer. With increasing age there was a tendency for the length of the terminal sickness to increase.

According to site (as recorded on death certificate), respiratory cancers accounted for 16 of the 22 cases lasting less than 100 days, 12 of the 17 cases lasting 100 to 199 days, and 4 of the 5 cases lasting 200 days and over. Seven persons lived from 164 to 327 days after being disabled from respiratory cancer.

No Record of Death During Period of Study

Nine cases of sickness due to cancer originated during 1940-50 for which there was no record of fatal termination in this period. One case of stomach cancer began in 1947 and lasted 39 days. In 1949 a case of lip cancer lasted 55 days. A gastrointestinal and a respiratory cancer each caused disability lasting beyond the maximum benefit period of 98 days. The worker with the gastrointestinal cancer had not returned to work by 1951, but there was no record of his death. The worker with the respiratory cancer died in 1951. There were five cases of disability due to cancer which began during 1950. One man with gastrointestinal cancer returned to work after an absence of 57 days. Another man with cancer of the lip was disabled 11 days. Two men with respiratory cancers and one man with cancer of the prostate were still sick at the end of 1950. Sickness of these men had already lasted 6, 11, and 7 months, respectively.

Table 7. Length of terminal sickness, by age and race

Deaths From Cancer and Other Causes

Death rates from cancer and other causes, 1940-50, are based on the same plants and the same years as in the previous section, namely, 7,818 person-years of membership. For the period covered by the sickness survey age-specific death rates have been calculated. All rates are expressed as deaths per 100,000 males on an annual basis.

Death Rates by Race and Age

It will be noted from table 8 that the cancer death rate for all males (562.8) represents 39 percent of the entire rate for all causes (1,458.2). The cancer rate for white males is 32 percent and for nonwhite males is 51 percent of the corresponding total death rates. At ages 45-54 and 55-64 years the cancer death rate among nonwhite chromate workers is higher than the rate for all other causes. In the general population of the United States the death rate from cancer had not reached one-fifth of the total rate even in those age groups where cancer is most important.

A racial comparison of cancer death rates shows a rate of 133.8 for whites under 35 years of age and 1,579.0 for those 65 years of age and over, with no deaths among nonwhites

observed in these age groups. In the most important productive years, namely, 35-44 and 45-54, the cancer rate for nonwhites was more than three times the rate for whites, and at 55-64 years it is more than double.

Death Rates by Race and Detailed Cause

Table 9 gives the number of deaths and death rates per 100,000 male chromate workers by race and specific cause. Of interest is the difference in the classification of causes of death by system for the white and for the nonwhite males.

Of the 75 deaths among white males, 34 (45 percent) were due to diseases of heart, arteriosclerosis, cerebral hemorrhage, and thrombosis, and yielded a total rate of 617.9. Nineteen (25

percent) were due to diseases of the respiratory system, including cancer of respiratory system, 14; tuberculosis of respiratory system, 2; and other respiratory diseases, 3. These diseases yielded a total rate of 345.3. Diseases of the digestive system, including cancer of digestive organs and peritoneum, caused 6 deaths; cirrhosis and other diseases of liver, 3; and other digestive diseases, 2; a total of 11, or a rate of 200.0 deaths per 100,000 white males. Of the remaining 11 deaths, 1 was due to cancer of nasopharynx, 1 to cancer of genitourinary organ, 1 to leukemia, 1 to Hodgkin's disease, 1 to nephritis, 1 to alcoholic psychosis, 1 to diabetes, 3 to nonindustrial injuries, and 1 to an ill-defined cause.

¹ Industrial injuries are not included. Data include experience of 2 plants during 1940-50, 1 plant during 1943-50, 3 plants during 1946-50, and 1 plant during 1949-50.

² 11 members who had been disabled more than 1 year and died during 1940-50 are not included. Of

these, 4 white members died of cancer; 2 white and 2 nonwhite members died of tuberculosis of respiratory system; 2 white members died of heart disease, and 1 nonwhite member died of pneumonia.

Note: Average number of person-years of membership: white, 5,502; nonwhite, 2,316.

Of the 39 deaths among the nonwhites, 27 (69 percent) were due to diseases of the respiratory system, including cancer of the respiratory system, 18; tuberculosis of the respiratory system, 6; and other respiratory diseases, 3. The total rate for diseases of the respiratory system, cancerous and noncancerous, was 1,165.8 deaths per 100,000 nonwhite males. Six deaths due to diseases of heart, arteriosclerosis, cerebral hemorrhage, and thrombosis yielded a total rate of 259.1 per 100,000 nonwhite males. Of the remaining 6 deaths, 1 was due to cancer of the digestive system, 1 to cancer of nasopharynx, 1 to meningitis, and 3 to nonindustrial injuries.

Comparative Mortality

The frequency of respiratory cancer apparently was above normal among chromate workers. Hence, an estimate of the excess in the number of deaths should be of interest. In table 10, death rates based upon the white and nonwhite male population of the United States, 1940-48, are compared with death rates for similar age groups among chromate workers.

During the 9-year period 1940-48, two plants

reported during 1940-48; one plant, during 1943-48; and three plants, during 1946-48. The number of person-years of membership in sick-benefit plans for each of the five age groups is shown in table 11.

Only in the oldest age group, 65-74 years, in the population of the United States were there an appreciable number of males not in the labor force; thus, the death rates for males aged 15 to 74 are based essentially on the working population. Because of the small number of person-years of membership in sick-benefit plans among chromate workers, attention should be centered on general trends rather than on particular age-specific rates.

Deaths Among All Males

In table 10 it will be noted that among all males the ratio of actual to expected number of deaths from all causes except cancer declines steadily with advancing age until it becomes favorable for chromate workers. For cancer, all sites, the actual number of deaths was approximately four and one-half times the number that would have been expected, based upon occurrence in the total male population of the

¹ Violent and accidental deaths are not included. Data for chromate workers include experiences of 2 plants during 1940-48, 1 plant during 1943-48, 3 plants during 1946-48.

² The average death rate for the United States for the 9 years, 1940-48, multiplied by the appropriate person-years of membership in the chromate plants.

³ Data are from references 2, 3, and 4.

United States. When cancer of the respiratory system was observed separately, the excess for chromate workers was greatly increased. Nearly 29 times as many deaths due to respiratory cancer were found as would have been expected. For three ascending age groups, respiratory cancer was 40, 30, and 20 times as common among male chromate workers as among other males. All other types of cancer

failed to show an excess among chromate workers.

Deaths Among Males, By Race

A comparison of respiratory cancer deaths, by race, shows that the ratio of actual to expected number was 14.29 for whites and 80.00 for nonwhites. On the other hand, the ratio of actual to expected deaths from cancer of all

Table 11. Person-years of membership in sick-benefit plans, by age and race

Race	Age, in years					
	Total 15-74	15-34	35-44	45-54	55-64	65-74
All males	5, 522	1, 574	1, 616	1, 411	796	125
White	3, 823	1, 041	1, 091	919	659	113
Nonwhite	1, 699	533	525	492	137	12

other sites was about what would be expected for whites (1.14), but was less than expected for nonwhite chromate workers (0.67).

For all causes of death except cancer the death rate for whites (941.6) was somewhat over, and the death rate for nonwhites (882.9) was somewhat under, that found in the general population (760.6 and 1,149.7, respectively). With advancing age, chromate workers of both races showed a decreasing trend in the ratio of actual to expected deaths from causes other than cancer.

The number of recorded deaths from respiratory cancer among the chromate workers is minimal for the following reasons:

1. Deaths of employees who were not members of a sick-benefit association are not included.

2. Persons who worked in chromates but left the industry prior to their terminal illness are not included.

3. Members who died over a year after onset of disability due to cancer are not included.

4. Several members who had a clinical course consistent with the presence of cancer of the respiratory tract are not included because cancer was not recorded on their death certificates.

5. Some members whose deaths were not recorded as cancer died without a complete medical examination or biopsy.

Summary

The morbidity and mortality experience of male members of sick-benefit associations in seven chromate-producing plants are described. Sickness among a group of white male chromate workers was compared with that of a large group of industrial workers. It was observed

that the annual number of cases of sickness and nonindustrial injuries per 1,000 white males was 116.3 for chromate workers and 108.4 for other industrial workers.

For all specific causes except cancer the chromate workers had frequency rates that were not greatly different from other workers. Cancer, with a rate of 7.1 for chromate workers compared with 0.7 for workers in other industries, stands out as markedly in excess for chromate workers.

The frequency of sickness among chromate workers has shown a trend downward during the past 5 years. The most marked decline has occurred among respiratory diseases.

Nonwhite chromate workers under 55 years of age had a higher rate for sickness and nonindustrial injuries than had the white workers. For cases lasting 8 days or longer the former had a frequency rate of 156.7 per 1,000 compared with 86.2 for the latter.

During the 9-year period 1940-48, the average annual death rate per 100,000 males aged 15 to 74 years for all causes was 1,503.1 for chromate workers and 927.8 for the corresponding male population of the United States; for all causes except cancer the death rates were 923.6 and 797.5, respectively.

For cancer, all sites, the actual number of deaths of chromate workers was approximately four and one-half times the number that would have been expected had the cancer rates for all males in the United States prevailed. When cancer of the respiratory system was observed separately for chromate workers, nearly 29 times as many deaths as were expected were found. Deaths from all other types of cancer failed to show an excess among chromate workers. A racial comparison of respiratory cancer deaths showed that the ratio of actual to expected number of deaths was 14 for whites and 80 for nonwhites; for cancer, all other sites, the two ratios were markedly lower.

ACKNOWLEDGMENTS

The authors wish to acknowledge the cooperation of chromate-producing companies who made records available and furnished assistance in securing information. The National Office of Vital Statistics of the Public Health Service advised on United States mortality statistics.

Body's Ability to Handle Fats

The identification and partial purification of two plasma components and one tissue component, which act in conjunction with heparin to clear lipoproteins produced in blood by heavy fat diets, has been accomplished by scientists at the National Heart Institute, National Institutes of Health, Public Health Service. Physical studies of plasma, employing a fast-spinning ultracentrifuge, indicate that clusters of low-density lipoprotein molecules are broken down into smaller components as a result of chemical reaction in the blood serum when suitable amounts of those components are added.

Important in the study of the causes and treatment of hardening of the arteries, these findings, which stem from research on the role of heparin in the body's ability to handle fat, are preliminary. Additional studies are needed before the data can be fully interpreted.

Accumulated evidence, substantiated by this study, strongly indicates that enzyme and hormonal factors play an important part in the clearance of lipoproteins in the blood, and suggests, therefore, that diet may not be the only factor—and possibly not even an important factor—in the body's ability to handle fats.

The scientists point out that although the means are available, the manufacture of a clearing factor in the body may only occur in response to the need at the time. The defect in metabolism may, therefore, lie in the inability of the mechanism to spring into action. This may be due to lack of one or more of the necessary factors involved in the clearing reaction.

A complete report of the research study was published in *Science*, May 30, 1952.

A New Antituberculosis Drug?

By ROBERT J. ANDERSON, M.D.

Announcement of the use of isonicotinic acid hydrazide (isoniazid) in the treatment of tuberculosis caused immediate and widespread reactions. The reports, published by New York newspapers at the end of February 1952, were accepted by the public with understandable enthusiasm. The professional attitude, however, was one of cautious open-mindedness. Aware that the limited clinical trial of the new drug was insufficient, the professional societies concerned at once warned the public against undue optimism.

"The introduction of a new drug in the therapy of tuberculosis is likely to raise more questions for a few years than it will answer. There is no knowledge at the present time that isonicotinic acid hydrazide or its isopropyl derivative will accomplish more than has been accomplished with streptomycin and PAS. It may prove to be an additional drug of great value. It may be years before its exact contribution to the therapy of tuberculosis can be assessed accurately." Thus spoke the American Trudeau Society.

The American College of Chest Physicians observed: "There has not been enough work or enough cases treated to be able to determine how this drug will fit into the present-day treatment of tuberculosis. If all the promise of effectiveness is fulfilled, this drug can do no more than add another weapon to those already used by

chest specialists in the treatment of tuberculosis. Whether this drug will extend the scope of treatment, decrease the time required, or change the approach to certain types of the disease has yet to be determined. It appears to hold great promise but should not be used as regular treatment in new cases until a great deal more is known about it and its reaction in the human being."

Cooperative Research

Seeking answers to such questions, and to others, the Division of Chronic Disease and Tuberculosis is conducting a comparative research project in cooperation with 22 tuberculosis hospitals. To evaluate the new drug, comparisons are being made between results obtained with isoniazid, alone and in combination with streptomycin, and results of treatment with a combination of streptomycin and PAS (para-aminosalicylic acid).

We hope to learn the comparative effectiveness of the new drug on the forms of pulmonary tuberculosis which comprise the majority of cases in this country. The study is planned not only to measure the influence of the different regimens on weight, temperature, disappearance of the bacillus, and X-ray changes, but also to learn about organisms resistant to the drugs, the success or failure of treatment, and death rates. We are particularly interested in knowing whether isoniazid will be useful for streptomycin-sensitive patients and those with streptomycin-resistant bacilli. Among 1,100 patients treated in the first 5 months of the study, 40 percent were streptomycin-resistant.

The pattern of cooperative research we are using is one which the Division of Tuberculosis

Dr. Anderson is chief of the Division of Chronic Disease and Tuberculosis, Public Health Service. This paper is an expansion of his remarks at a panel discussion at the forty-eighth annual meeting of the National Tuberculosis Association at Boston, May 26, 1952.

developed in 1949 for testing streptomycin therapy. A similar research project in 1950 studied the combined effect of streptomycin and PAS, a combination now widely used against tuberculosis. A number of hospitals pool their cases and cooperate in one coordinated investigation. In a relatively short time observations on groups of comparable cases can be assembled in numbers large enough to yield decisive results.

The protocol of the isoniazid study was agreed upon in advance by the participating clinicians, who report their observations every 4 weeks to our office, where they are analyzed statistically. The names of patients to be included in the study are submitted to the central office in order that the patients may be placed on a treatment course which is determined by random allocation. Each patient is placed on one of the drug regimens, and will receive such other treatment as his physician prescribes. Only patients with X-ray evidence of pulmonary tuberculosis and positive bacteriology are eligible, and provision has been made to keep the welfare of the patients paramount without jeopardizing the validity of the study. Each will be treated with the drugs for 40 weeks and watched for an additional 24 weeks.

Future Implications

Until studies such as this are completed, any comments about the future implications of isoniazid must necessarily be highly speculative. We are dealing with a chronic disease of very long course, characterized by a wide range of possible manifestations, slow response to therapy, relapses, and prolonged treatment. Until much more evidence is in, we can only hazard guesses. The effect of isoniazid and the permanency of that effect on the patient's disease have not yet been determined. Drug-resistant bacilli already have been reported. There are many other important questions still unanswered. On the other hand, we must be alert to utilize even partial knowledge of the drug; even interim findings may be valuable.

Even in the event that the new drugs prove to be extremely efficacious, the program of tuberculosis control through public health measures will not be altered appreciably, in my judg-

ment. The principal effects of isoniazid most probably will be to make case finding and hospitalization even more urgent.

Isoniazid brought tuberculosis dramatically to the attention of the general public, many of whom believed the disease had been vanquished years ago. I think we would be wise to make capital of the renewed interest in tuberculosis which announcement of the drug has stimulated. If isoniazid disappoints us, as other therapies have disappointed us and our patients in the past, the extra vigor we invest now in case finding will tend to offset the let-down in public interest which may come in the future. And if isoniazid lives up to its early promise, as we all hope, surely we will want to strengthen and extend our efforts, so that all who need it may have the new treatment.

The implications of isoniazid for hospitals are not clear at this early stage. But if we assume that no toxic properties will be revealed and that resistance can be dealt with, then the properties claimed for the drug—that it reduces fever and restores appetite—alone would make it useful. If therapy with isoniazid requires less time than present therapeutic methods, turn-over in hospitals could conceivably be rapid. To the extent that it shortens the length of patient stay, the new drug could reduce the number of hospital beds needed.

Effective as they are in preventing or postponing death, streptomycin and PAS prolong hospital stay and also cause more patients to seek hospital care. In addition, some patients are so benefited that other forms of therapy, including surgery, can be employed. Therefore, unless it is rapid in action, an improved therapy very probably would aggravate the shortage of tuberculosis beds. For the same reasons, the number of cases requiring supervision by health departments would be increased correspondingly.

Measuring Control

The assertion is sometimes made that tuberculosis is a disappearing disease in this country. In large part, such views are based on the trend of mortality, which has been dramatically downward. Nevertheless, tuberculosis remains the seventh leading cause of death and the only

communicable disease among the first 10 causes of death. In the age group 15 to 34, tuberculosis is the leading cause of death from disease. From the standpoint of mortality then, the "disappearance" of tuberculosis seems to have been more advertised than achieved.

In any event, the dimensions of the tuberculosis control problem are seen more realistically when viewed in the light of morbidity data. The best estimate is that there are now 1,200,000 people in this country with tuberculosis, who may be placed in four groups. First there are the 500,000 persons with tuberculosis who are known to their health departments. Half of these are active cases. In addition, an estimated 700,000 persons with either active or inactive tuberculosis are not known to any health department.

Only 105,000 of the 250,000 persons known to have active tuberculosis are in hospitals now. Among the 145,000 known active cases of tu-

berculosis who are not hospitalized are 40,000 persons with positive sputum. These are the patients for whom additional beds are urgently needed. Then there are about 30,000 persons whose tuberculosis seems to be progressing, according to X-ray, although their sputum was negative when last tested. The remaining 75,000 persons with known active tuberculosis who are at home have not had a sputum examination reported during the past year.

Whether mortality or morbidity is used as a measure, tuberculosis is still far from controlled in the United States, despite all of the efforts directed against it by the health professions. To deal with a public health problem of this magnitude, the Nation obviously needs more tuberculosis beds, more clinics and equipment, more and better-trained health department personnel. The development of improved therapeutic methods emphasizes these pressing needs.

Trend in Hospital Utilization, 1951

A new high in hospital admissions was reached in the United States in 1951, according to the report on hospital services by the Council on Medical Education and Hospitals of the American Medical Association. During the year, 18 million patients were admitted to 6,637 hospitals, a rate of one every 1.75 seconds. More than 427 million patient-days of care were recorded.

Hospital births also set new records in 1951. Three million births, almost 90 percent of the total recorded, took place in hospitals, the association report states.

Needed Improvements in Mortality Data

By IWAO M. MORIYAMA, Ph.D.

In reviewing the 50-year history of national mortality statistics in the United States, one is impressed by the fact that death statistics have not changed basically since 1900. However, this does not mean that progress was not made in the development of mortality statistics. Perhaps the most important of these developments was the growth of the registration area into a federated system of vital records and statistics with a nation-wide coverage. Another major advance was the establishment in 1937 of place-of-residence data on an annual basis for each area in the country.

The availability of data on a routine basis over a relatively long period, for small geographic areas, and in considerable detail as to cause is perhaps the most important factor in the widespread use of mortality statistics. Mortality statistics are frequently utilized as a substitute for morbidity statistics. The validity of this type of use is open to question, particularly when diseases with low fatality rates are under study. For example, one could hardly expect to measure the prevalence of rheumatic fever, or the mental disease problem, or the nutritional status of the population by the use of mortality statistics. On the other hand, mortality data still provide the best available index of incidence of a number of communicable diseases.

The quality of mortality statistics has im-

proved markedly over the past 50 years. The International List of Causes of Death, through its decennial revisions, has kept pace with medical progress, and medical certifications of causes of death have greatly improved. Medical returns are more complete, as indicated by the increase in multiple-cause reporting from 35 percent in 1917 to 55 percent in 1940. It is expected that in 1950 the proportion of multiple-cause reporting will prove to be in the neighborhood of two-thirds of all deaths. The percentage of ill-defined and unknown causes has been declining steadily—an indication of the improvement in the quality of cause-of-death reporting.

Despite the progress made in the development of mortality statistics over the years, there are a number of defects that seriously limit the usefulness of the data. If mortality statistics are to continue to serve as tools in public health programs, there need to be further improvements in the quality of the basic data. The scope of public health problems cannot be precisely defined, nor can programs be planned or evaluated effectively with imperfect tools. It is also important that there be extensions in the use of data that can be obtained from the death registration document. Lastly, there needs to be development of new information using the death certificate as the starting point.

Needed Improvements in Quality of Data

Death Registration

One of the basic defects in many geographic areas is the incompleteness of death registration. Although the completeness of death registration has never been precisely measured, there is evidence that many deaths are not regis-

Dr. Moriyama is chief of the mortality analysis branch, National Office of Vital Statistics, Public Health Service. This paper was presented at the Second Conference on Public Health Statistics at the University of Michigan School of Public Health, Ann Arbor, June 18, 1952.

tered. This, despite the fact that the law usually requires the filing of a death certificate in order to secure a burial permit. An examination of the death rates for any number of counties will show crude death rates of much lower magnitude than can be accounted for on the basis of known mortality levels and age distribution of the population. In many instances, it is almost impossible to interpret the death rates for small areas because of incomplete registration. Since public health programs are carried out in the local areas, improvement in death registration is essential if valid data are to be available for program planning and program evaluation.

Place of Residence

In addition to complete registration, there needs to be further study of the problems of residence allocation. Since data by place of residence are generally used as an index of mortality in a community, accurate classification of data is essential. This is not a simple problem because the "usual place of residence" is not as clear cut or definitely determinable as the place of death. A study of this problem is being initiated, and it is hoped that the results will be useful in clarifying the situation with respect to the kind of information being reported as the place of residence, and how accurately such events can be classified.

Intercensal Population Estimates

Population estimates are not a problem in mortality statistics, but they should be mentioned here because the availability of reliable annual estimates of population, particularly for small areas, will extend the usefulness of mortality data. Reliable population data are needed more than once a decade.

Accuracy of Information

There are several items on the death certificate for which more complete and accurate information is needed. Mention has already been made of the usual-place-of-residence item. The others of special interest are the statements of age, marital status, occupation and industry, and the medical certification of causes of death.

Misstatements of age, particularly for those around age 65, are becoming of increasing im-

portance because of their effect on death rates for the older population. Unless the population data contain the same proportionate bias as mortality data, death rates for studies of mortality in the aging population will be misleading.

Statistics on causes of death are used more extensively to define health problems than any other kind of mortality data. For precision in definition, further improvements in medical certification are needed. To close the gap between the needs and the work currently being done in this area, the Public Health Conference on Records and Statistics is recommending to all States that an intensive program be carried on over the next 2 years to secure improvements in medical certification.

The quality of cause-of-death reporting today varies considerably from area to area. For the country as a whole, it is estimated that perhaps 20 percent of the medical returns are not properly made. At the fourth annual meeting of the Public Health Conference on Records and Statistics, in Washington, March 25-28, 1952, Florence Olson reported to the mortality statistics working group that, in a recent survey of State cause-of-death query programs, it was found that the State vital statistics offices were querying, on the average, about 3 percent of the cause-of-death statements.

The classification of causes of death has been put on a sounder basis, but the benefits of this change cannot be fully realized until more reporting physicians assume fully their responsibility. The certifying physician must now be concerned with how the causes of death are reported as well as what should be certified. A number of tools, such as a filmstrip on medical certification of causes of death, and new procedures for querying causes of death, have been developed to bring to physicians the proper method of medical certification. Vital statistics offices should make more effective use of these tools and develop others to secure needed improvements in the quality of cause-of-death statistics. In this connection, it is hoped that more local health officers will become actively engaged in informing the medical practitioners in their areas of the proper method of medical certification. Routine examination of death certificates will indicate local problems. Dis-

cussion of these problems with individual physicians, or before the medical society and hospital staff, has been effective in securing almost immediate improvement in the quality of medical certification.

Accuracy of Diagnoses

The death certificate even under ideal conditions can do no more than register the physician's knowledge and medical opinion regarding causes of death. In interpreting statistics derived from these reports, it is important to know about the reliability of medical diagnoses. This is obviously not a statistical problem but a medical one. Also, it is a problem that will always exist in one degree or another no matter how much medical progress is made. Although the actual numbers of deaths from particular diseases are of interest to public health program directors, the establishment of the "true" numbers of deaths or death rates is not practical, except in rare instances. However, it does seem feasible to make an evaluation of medical diagnoses from a sample of death certificates. If the death occurred in a hospital, a follow-back can be made to the hospital records and to autopsy reports if a necropsy has been performed. In other cases, the follow-back can be made to the certifying physician. In these follow-backs, information would be collected which would permit some evaluation of the accuracy of diagnoses.

Causes of Fetal Deaths

With the great progress made in the saving of infant lives, it is expected that attention will be shifted to a public health problem of great magnitude—fetal deaths. Data are not yet available to measure the size of this problem, but estimates indicate that the annual fetal loss is much greater than that ever caused by infant deaths. The World Health Organization has recommended that statistics be compiled on the fetal death problem.

Little is known about the causes of fetal deaths. Experimental studies are now under way to determine the best method for collecting data on this subject. The problem here is not simple since the fetus cannot be observed clinically. It is hoped that eventually the

statistics on fetal deaths will be as useful as general mortality statistics.

Extending Use of Available Data

There are still some opportunities for extension of mortality data from information available on the death certificate but not regularly processed into statistical tables. The most useful data not tabulated regularly are those related to multiple causes of death, mortality statistics by social classes, mortality experience of industrial groups, and statistics from the matching of birth and death records.

Multiple-Cause Tabulations

A good deal of medical information is available on the death certificate. When more than one cause of death is reported and only one cause is tabulated, then only a segment of the reported information is used. Also, single-cause tabulations limit the interpretation of cause-of-death statistics.

Multiple-cause tabulations provide information on the various diseases or conditions contributing to death. A count of diseases or conditions is made without regard to individuals, whereas the single-cause tabulations represent counts of individuals who died as a result of a particular cause that initiated the train of morbid events leading to death. Roughly speaking, multiple-cause tabulations show diseases and conditions present at the time of death or associated with the death; primary mortality tabulations indicate deaths from a particular disease or condition.

The results of a full-scale study of multiple causes of death are not yet available. However, a preliminary report of the study being conducted by the Illinois State Health Department was presented by John H. Vinyard to the mortality working group of the Public Health Conference on Records and Statistics at their meeting in Washington, March 25-28, 1952. In coding death certificates for the period April to June 1951, it was found that of the 22,481 death records involved, 11,616, or 52 percent of the total for the period, reported deaths due to multiple causes. Also, there were 15,910 causes certified in addition to the 22,481 causes which are classified as the underlying cause of death.

eliminates useless tabulations, but also points to needed improvements in the data as well as to new areas for study. More important, data in usable form lead to interpretations which can be utilized in public health programs.

In many areas, vital statistics are an integral part of the activities of the health department. In others, the vital statistics activities appear to be merely housed in the health department. This detachment is helpful in maintaining a strictly objective attitude toward the data, but it does not discharge the responsibilities of the statistical office. Mortality statistics are tools to be used in planning and evaluating public health programs, and statistical findings are of no value if they are modestly hidden. There should also be more knowledge of program needs and anticipation of these needs by statis-

ticians. If the statistical offices can be adequately staffed by competent personnel, sound bases for the planning of health programs can be developed.

Insofar as mortality statistics are concerned, it seems fair to say that they are here to stay, despite the crying need for morbidity statistics. There are many areas in death statistics that need improvement. New statistics should be developed to meet health program needs. There is life in mortality statistics waiting to be brought out by the statistician, and to be used by the administrator and program directors.

A Program of Conservation Irrigation

The headquarters of the newly established water projects section of the Public Health Service Communicable Disease Center has been opened in Salt Lake City, Utah. In the western United States, where the program will operate in 17 States, one of the major health problems and a major goal of the new office is the control of mosquitoes.

The section will cooperate with State health departments and Federal water development agencies in a "conservation irrigation" program to control insects of public health significance associated with the development of national water resources. Application of the principle of "conservation irrigation," a concept of the Soil Conservation Service, can greatly reduce the hazard of mosquito-borne disease.

Irrigation, which has opened some 22 million acres of arid and semiarid land to the production of food, often results in the breeding of mosquitoes and the spreading of the diseases they carry. Studies made in the past have shown that as many as 20,000,000 eggs of one type of mosquito may be present on a single acre of irrigated pasture, and a new brood may be produced following each flooding of the area throughout the irrigation season.

Nutritional Problems and Civil Defense

By Sir JACK DRUMMOND, D.Sc.

The foundation of any scientific plan for feeding a civilian population in time of war must be estimates of man's daily need, under various conditions, for essential nutrients. I well recall the anxiety with which we searched the literature in 1939 in order to compile a list of such requirements and the trepidation with which we applied them to calculations of food supplies. In times of peace, scientists can amiably disagree over the need for ascorbic acid without arousing any fears, but the difference between 10 mg. and 50 mg. a day represents a formidable quantity of the vitamin itself or of foods rich in it when the population factor of 44 million has to be applied in times of rigid economy.

You will all recognize how insecure was the foundation of our 1939 calculations by comparison with that now provided by the experimental and practical experience gained during and since the end of the war. There are disagreements between the findings of the two expert bodies that have reported recently. The National Research Council and the British Medical Association do not see eye to eye on every assessment, but the differences are negligible when set against the important fact that there is full agreement on energy requirements.

None of the many lessons we were taught by

practical experience during the last war approaches in importance the outstanding demonstration in Western Europe that the provision of energy dominates the nutritional picture. That is not to say that the importance of calories was underestimated. Calories were given much attention, but qualities of food other than their equivalence of energy occupied our thoughts to an extent that now appears to have been unnecessary. It is easy to be wise after an event, so I have no hesitation in expressing the view that the outstanding problem facing those who will be responsible for feeding the civilian population, should another war burst upon us, is to find ways and means of providing the daily energy requirements of the people in the form of palatable and acceptable foods.

Calorie Deficiency Most Harmful

Time and time again during the war years striking illustrations were recorded of the harmful effects of calorie deficiency on working capacity, physical condition, and morale. By contrast, examples of ill health caused by protein deficiency or shortage of vitamins were distinguished by their rarity. I am referring, of course, to conditions in Western Europe, not to those that prevailed in the Far East. I imagine, however, you have in mind, in studying your own problems, conditions comparable with those that we in Great Britain experienced and that affected also France, Belgium, Holland, and other adjacent countries. With such foods as inevitably form the basic diet under these conditions there is small risk of any nutritional disorder arising.

To justify this statement let me give you two examples. During the worst period of the war,

The late Sir Jack Drummond was the scientific adviser to the Ministry of Food of the United Kingdom, 1939-46. His was the opening paper of the scientific section of the combined conference at Church House, Westminster, December 3, 1951 (see Public Health Reports, July 1952, p. 607).

the winter of 1940-41, when the food supply situation was truly alarming and when civilian morale was being sternly tested by heavy bombing, we, at the Ministry of Food, were under considerable pressure to distribute vitamin preparations to stave off nutritional disaster and boost morale. Our calculations indicated that the food of the people, restricted as it was, provided a sufficiency of all essential nutrients. On that conclusion we stood firm and declined a generous offer to provide what would have been needed to make a nation-wide distribution. A decision that was then taken on what was admittedly rather shaky scientific evidence was amply justified later. A glance at the record of the years 1940-49 recently published by the Ministry of Food (*The Urban Working-Class Household Diet*, H. M. Stationery Office, 1951) makes that clear.

My second example also concerns vitamins. When representatives of the Allied powers were planning in 1943 the relief of the populations of occupied Western Europe, there was again a loud and insistent demand that huge quantities of vitamin preparations of one kind or another be included in the supplies of food to be brought up in the wake of the liberating armies. Intelligence reports had given a grim picture of the widespread incidence of malnutrition among the populations of the large towns and had laid stress on the need for vitamins. Disregarding these reports (intelligence reports concerning what the townspeople were actually eating, as distinct from what they were able to obtain as rations, were disconcertingly misleading), we based a decision on the common-sense reasoning that as rations of staple foods decrease people strive to eke them out with whatever else they can acquire by hook or by crook. Vegetables usually make up a large part of what can be so obtained, and these, together with the increased extraction of cereal flour that is an inevitable consequence of food shortage, tend to raise the general level of vitamin intake. Again, the decision was fully justified when the condition of the urban populations was examined on liberation. Apart from rare cases, appropriate for medical rather than nutritional treatment, the picture in every town of Western Europe was the simple one of deficiency in calories.

Starling coined in 1915 the aphorism "take care of the calories and the proteins will take care of themselves." Had he been dealing with the food situation in 1939-45, he would have been tempted to link with the proteins all other essential nutrients, for it is certainly true that the shift of balance of foods which wartime restrictions nearly always impose tends to raise the intake of vitamins and of important mineral elements. Under the conditions of emergency that form the background to the study of civil defense the problems of food supply become considerably simplified if this argument is accepted. I firmly believe that the history of the last war provides a wealth of evidence to justify its acceptance.

Need 2,900 Calories a Day

I see the major civil defense nutrition problem to be the provision of enough food for all to satisfy hunger, bearing in mind that hunger is closely attuned to energy needs. In round figures that represents 2,900 calories per head per day in the form of supplies to the family. It is a curious fact that this figure applies to a wide variety of conditions of life. It is not greatly influenced by the proportion of the population engaged in heavy physical work nor by different food habits. It is changed substantially only when there is a high proportion of children in the population, as, for instance, in Italy and Eastern Europe.

An energy provision equivalent to 2,900 calories per day per head will not only enable a population to undertake physically all the tasks a grave emergency will present, but with equitable distribution of foods such as were available in Great Britain during 1939-45, it can be made to cover all nutritional requirements without recourse to artificial supplementation of the diet. That, I submit, is a fact of immense practical importance too often obscured by academic discussion of what are, in fact, much less vital problems.

The question of palatability is of no less importance than that concerning calorie supply. Hundreds of striking examples can be drawn from wartime experience to demonstrate how carefully devised nutritional plans can be wrecked by disregarding people's likes and dis-

likes. The half-starved people of Malta threw dried eggs into the street rather than eat an unfamiliar food; rice-eating Hindus in the great famine died before they would touch the millet which relief brought; our troops wore themselves to skin and bone in the Burmese jungle rather than endure the monotony of living exclusively on the famous K ration, one of the most scientifically compounded of all the wartime rations. These facts must not be ignored now that we are again taking stock of the situation. On the contrary, they must color our every thought on emergency feeding. We found by experience in Great Britain that people shaken by bombing don't relish a bowl of hot soup and biscuits. They want a cup of hot, strong tea! It would, I imagine, be coffee if American cities were attacked. Give urgent and serious attention to such problems; their solution will be half the battle won!

Returning now to the all-important calories, consideration must be given to the contingency, a very probable one, that the full provision equivalent to 2,900 calories per head per day cannot be achieved. Any substantial reduction below this figure means either that all go short or that selected groups (e. g., heavy workers, children) have priorities that further reduce the shares of the less fortunate. With the arguments for and against selective rationing I am not here concerned. The whole question is fraught with difficulties and can only be rationally approached in the light of the special circumstances prevailing at the particular place and time. But, however the distribution may be made somebody will have to go short and that somebody will suffer.

Effects of Calorie Deficiency

One deep impression made by the experience during the war is that deficiency of energy intake is associated with signs of a very characteristic nature, signs more immediately recognizable than any of those associated with lack of vitamins or protein about which so much has been written. From the practical standpoint the consequences of energy deficiency are vastly more important than those of any other shortage. They affect morale surprisingly quickly. Discontent, grumbling, and irritability are

characteristic signs associated with a reduction in calorie intake of the order of 20 percent, particularly when it affects those engaged in physical work. The loss of weight related closely to the negative calorie balance is of less importance than the disturbances of mental balance. The picture presented by the underfed victims of the war coincides exactly with that drawn by Dr. Ancel Keys from the close study of his volunteers. It is a picture that calls for the closest study by all who are concerned with food plans to meet a new emergency.

As the food supply is reduced below that required to provide the requisite 2,900 calories per head per day there are two clearly marked levels which can be called critical. The first can be placed at about 2,000 calories. Down to this point it is not difficult to devise differential rationing systems which will enable all groups of the population to get along tolerably well for a considerable time. The output of work will not be optimal and there will be other signs of energy deficiency apparent, but in general the picture will not be disturbing. But below this level the task of allotting the available food will become more and more discouraging until a point is reached at about the level of 1,500 calories at which it is quite impracticable to do more than plan for survival unless part of the population is deliberately subjected to starvation in order to enable the remainder to work, as was done in Leningrad during the siege. I am referring, of course, to periods of more than a few weeks.

In summary, my views on the problem seen in its broad perspective can be condensed into two simple conclusions:

1. In the first place attention should be concentrated primarily on the provision of energy. Apart from the special case of mothers and young children, other nutritional requirements are of quite secondary importance.

2. The palatability and acceptability of the foods to be distributed are qualities of the very highest importance. It is of far greater moment to give people in an emergency food they will wish to eat than to offer them something that is nutritious but unappetizing.

Food Supply and Emergency Feeding In Civil Defense

By PAUL B. MURPHY, LEONARD R. TRAINER, B.S.,
and JAMES M. HUNDLEY, M.D.

The need for feeding the homeless and injured as soon as possible after a disaster has been demonstrated repeatedly. Emergency feeding is important not only to maintain the nourishment of the affected individuals, but it is essential for morale purposes. The experience of Great Britain during World War II demonstrated that a hot drink and a warm meal immediately after a disaster often marked the point at which individuals began to pull themselves together.

A community which can organize mass feeding within several hours after a disaster vividly demonstrates that it is still functioning, and this demonstration tends to allay anxiety and panic. Of equal importance in maintaining morale and in allaying public anxiety is the resumption of

normal food wholesaling and retailing at the earliest possible moment. Finding food in the shops where the public is accustomed to seek it constitutes a major step in the return to "normalcy" and additional evidence that the community is functioning and will survive the disaster. Furthermore, this enables those who can remain in their homes to procure food and thus relieve the burden on public feeding facilities.

Disasters from natural causes are not strangers in the United States. Many organizations, especially the Red Cross, have had extensive experience with this type of problem. However, man-made disasters, which atomic weapons could produce, pose problems of a magnitude and complexity not experienced in this country. Should one or more of our major cities be subjected to atomic attack or to intensive conventional bombing, the resources of large sections or regions might have to be mobilized. A nationally integrated plan is necessary.

The Federal Civil Defense Administration (FCDA) has developed plans and recommended organizational patterns which can be adopted with reasonable uniformity in all parts of the Nation and which should result in the activation of State and local units capable of meeting any anticipated situation when functioning singly or collectively.

Mr. Murphy is food consultant for the Federal Civil Defense Administration and was chairman of the United States delegation to the Combined Conference on Administrative and Scientific Aspects of Food in Civil Defense, London, November 26-December 13, 1951 (see Public Health Reports, July 1952, p. 607). Mr. Trainer is director of the food distribution branch, Production and Marketing Administration, Department of Agriculture. Dr. Hundley is consultant on nutrition for the Federal Civil Defense Administration.

This paper is based on material presented at the London conference. A second paper, by Dr. Hundley, which follows on page 864, outlines the primary characteristics of emergency food reserves.

Food Supply

The National Level

It is evident that after attack the requisite supplies of food should be available whenever

and wherever needed for mass feeding and for home consumption. The basic plan calls for necessary food supplies to be available in normal commercial channels rather than in special stockpiles or reserves. Two Federal agencies—FCDA and the Department of Agriculture (USDA)—share primary responsibility at the national level. Both agencies with full recognition of the interdependence of their respective responsibilities have developed a joint plan for emergency feeding.

The Department of Agriculture has the basic responsibility for the Nation's food supply and for securing maximum food production to meet all needs, including emergency feeding. Further, USDA is responsible for directing food distribution—except actual rationing—so that necessary supplies will be available. USDA has the responsibility of instituting cooperative programs with the food industry and with food wholesalers and retailers to assure that the system of commercial food distribution carries sufficient food inventories to meet both current consumption and emergency food needs. In an actual emergency, USDA will effect any regional or national redirection of food distribution which may be requested by the Federal Civil Defense Administration to assure delivery of food supplies to damaged cities and to reception and evacuation areas as soon as possible after attack, or to areas affected by civil defense operations. USDA also is responsible for assuring adequate food supplies during reconstruction and rehabilitation pending the reestablishment of normal food distribution channels.

Federal Civil Defense Administration works closely with USDA in implementing the above plans and in obtaining the voluntary cooperation of the entire food industry on a nationwide basis. The fullest cooperation of the food industry and the food trade is essential at national, State, and local levels if the plans outlined are to function effectively.

Federal Civil Defense Administration has the further responsibility for perfecting and sponsoring operational plans which will translate the national plan into effective functioning programs at the State and local levels. FCDA Policy Memorandum No. 10 and FCDA Advisory Bulletin No. 78 have been distributed to all

State and major local civil defense units. They describe in detail the State and local plans recommended.

Leadership in the State

FCDA recommends that, at the State level, the governor or the civil defense director appoint a civil defense food director who is thoroughly familiar with the food industries in the State. In most instances, the food director should be a volunteer from leaders within the food industries of the State. The food director

Leadership Channels for Emergency Feeding

NATIONAL . . .	Federal Civil Defense Administration Department of Agriculture
STATE	Governor and Civil Defense Director Civil Defense Food Director—Chairman of Food Advisory Committee Food Advisory Committee—1 member from each local food advisory committee
LOCAL	Civil defense directors in major trade centers Civil defense food advisory committees Directors of emergency feeding in civil defense units Department of Agriculture consultants Representatives of local food industries Caterers and restaurateurs Volunteer workers

would serve as chairman of the State food advisory committee which would include one member selected from the membership of each local food advisory committee.

The State civil defense food advisory committee should perfect, with civil defense supply and transportation divisions cooperating, plans to procure and transport necessary food. A uniform plan of voluntary controls covering the

sale of food for the entire State should be developed in the event of attack.

Local Leadership

A local civil defense food supply advisory committee should be appointed by the local civil defense director in each major jobbing center in the State. The area supervisors of the food distribution branch, Production and Marketing Administration, USDA, are available for consultation in choosing the centers. The local committee should include local representatives of all the important fields of the food industry.

The local food committee functions the same as the State committee but is limited to respective local areas. In addition, the committee must establish a working relationship with local leaders in charge of emergency feeding. Estimates of the food requirements for feeding the homeless, for feeding in hospitals, and for feeding essential civil defense workers and other groups must be obtained so that the food committee can determine the magnitude of its task in light of available resources.

Precise definitions of responsibility must exist among the various local divisions of civil defense assigned to activities related to emergency feeding. The local units must have a clear channel to their respective State and regional organizations, and they, in turn, to their national organization.

Emergency Feeding

Advance planning is essential. Each local civil defense unit must develop an organization capable of preparing and serving meals on a mass basis with limited facilities. Normal water supplies may be unavailable. Public utilities will undoubtedly be disrupted. Electricity and gas for cooking may be unavailable. Plans must be considered for using alternative cooking fuels—bottled gas, solid fuels, or emergency generators—and for cooking with improvised equipment. Thousands of meals may have to be served under primitive conditions and with only a few hours' notice.

A director of emergency feeding must be appointed in each local civil defense unit. The existing facilities for the mass preparation of food must be surveyed. Sites must be selected

for feeding the homeless, the injured, and evacuated groups. The selection must be done in consultation with local leaders who are responsible for medical services and for other civil defense divisions. Plans must be made to feed essential civil defense workers engaged in fire fighting, rescue work, and repair of public utilities. Because workers may have to be fed where they are working, the transportation of prepared food will be another problem.

The facilities of caterers and restaurateurs should be fully utilized. Arrangements should be formalized with these groups so that they can secure food and go into action with a minimum of delay when authorized to do so by competent authority.

The importance of advance planning and organization for emergency feeding cannot be overemphasized. It is obvious that the best food supply arrangements will be useless if personnel and facilities are not available to transform the raw food supplies into nourishing, acceptable meals. It is also obvious that many workers will have to be available and trained.

Recruitment and Training

Groups of volunteers must be recruited, organized into teams, trained, and assigned to the selected feeding centers. The experience and "know how" of dietitians, nutritionists, home economists, commercial chefs, as well as church groups, and such public feeding groups as school lunchroom personnel, should be utilized in training activities. The existence of experienced local Red Cross units in many areas constitutes a valuable resource not to be overlooked.

Coordination of Activities

The activities of the emergency feeding group must be coordinated with other aspects of mass care—clothing, shelter, and evacuation.

It is especially important to establish a sound working relationship between the emergency feeding program and health services. The responsibility for feeding in temporary hospitals and in first-aid stations, for the training of the necessary workers to prepare and distribute the

food, and for provision of the required quantities of food must be clearly understood. Any special foods or abnormal quantities of specific food items which will be required by the medical services should be known in advance in order to arrange necessary procurement.

The sanitation services also have important functions in emergency feeding not only with respect to food sanitation but also to safe water supply, garbage disposal, and to the special problems posed by atomic, biological, or chemical warfare.

International Rheumatic Fever Study

An international cooperative study of rheumatic fever, the first of its kind, has been under way since early 1951 at 13 research centers in the United States, Great Britain, and Canada. Scientific investigators of the three nations are measuring the comparative values of treating rheumatic fever with one of the hormones—ACTH or cortisone—or with salicylates. Although the acute symptoms of rheumatic fever usually subside with all three agents, no clear difference has as yet been established in the rate of completeness of this improvement, according to the preliminary report of a panel of investigators.

A summary statement of the findings in the preliminary report was presented in June to a joint scientific session of the Council on Rheumatic Fever and the American Rheumatism Association in Chicago. The text follows:

"A group of investigators in the United Kingdom, Canada, and the United States initiated in January 1951 a cooperative study on the relative value of ACTH, cortisone, and salicylates in the treatment of rheumatic fever and the prevention of rheumatic heart disease. The plan of study provides for uniform criteria for the diagnosis of rheumatic fever and for the degree of rheumatic activity required for the admission to the study, the random allocation of patients to the three treatment groups, a defined dosage schedule of the drugs for a fixed period of time, a specified period of observation following treatment, and a long-term follow-up schedule. It also lays down precisely the fre-

quency and type of clinical and laboratory observations to be carried out on each patient.

"To date, in all three countries, 658 cases have been admitted to the study, and the analysis of rather less than half of these is the basis of the preliminary report. These cases were analyzed for changes in those symptoms, signs, and laboratory observations usually considered important in evaluating the course of acute rheumatic fever. In the type of cases admitted to the trial and with the regimen of treatment laid down, it appears that individual symptoms, signs, or laboratory observations may have been affected more favorably by one or another of these three drugs, but no consistent pattern is evident. In short, no firm conclusions can at present be drawn concerning the drug most effective in the control of the acute illness. The cases have not been under observation sufficiently long to provide data on the prevention of rheumatic heart disease.

"Admission of new cases to the study will be brought to an end later this year. It is anticipated that a total of 750 cases will be available in all three countries for complete and detailed analysis of the effects of the drugs on the acute course of the disease and later, after adequate follow-up, on the prevention of rheumatic heart disease."

Funds for the international study are being supplied by governmental and voluntary health agencies in the three nations and include the National Heart Institute of the Public Health Service, Federal Security Agency.

Necessary Foods for Emergency Feeding

By JAMES M. HUNDLEY, M.D.

The joint policy of the Federal Civil Defense Administration (FCDA) and the Department of Agriculture (USDA) provides that foods for emergency feeding shall be made available from existing commercial stocks and through normal distribution channels. To accomplish this, the food industry and food transportation facilities would be organized nationally and locally to deliver needed foods to emergency areas. The FCDA-USDA plan for emergency feeding poses problems which are primarily administrative. It does not present any immediate problems from the standpoint of nutrition or food technology.

This emergency feeding plan does not preclude the FCDA-recommended practice that all families with infants under 1 year, and families in critical target areas especially, should maintain in their homes—at all times—a rotating 1-week supply of canned evaporated or similar acceptable milk product, necessary cereals, and other special foods for infants. It does not preclude the desirable, and normal, practice in most families of maintaining a rotating pantry supply of food sufficient for 3 or 4 days.

Nor do the joint-planning agencies—FCDA

Dr. Hundley is chief of the Laboratory of Biochemistry and Nutrition of the National Institute of Arthritis and Metabolic Diseases, Public Health Service. He is also consultant on nutrition with the Health and Special Weapons Defense Division of the Federal Civil Defense Administration.

This paper was presented, in outline, before the scientific section of the London Food Conference on December 3, 1951 (see Public Health Reports, July 1952, page 607).

and USDA—visualize the establishment of any special food stockpiles to be held in readiness for emergency use. Proper organization of food and transportation industries would make stockpiling unnecessary—at least under prevailing conditions. However, it is possible to visualize situations and to anticipate developments which might make it imperative to supplement the existing plan by establishing special stocks of food.

Therefore, it is important to examine and classify the technical information which would govern the establishment and management of food stockpiles, to define areas in which our knowledge is deficient, and to list the foods and food products which are suitable for this purpose. This information should be developed in a form which can be utilized on short notice.

What plans have been considered for providing reserve stocks of food under emergency situations?

Family Food Stocks

In time of emergency, the practice of maintaining a rotating family food shelf should be officially encouraged as much as may be consistent with national food supplies and with due concern for the prevention of hoarding. No technological problems are posed by the family food shelf plan since the foods would be staple products normally procured and used, they would be rotated frequently, and their characteristics are well known to every housewife. Goodhart and Jolliffe (1) have suggested food items which should be included in this family food shelf.

A family food package might be designed as a special packaged ration—or group of pack-

aged foods—for a day's supply sufficient for a family of four. It could be set aside as a permanent reserve and stored in basement and shelter areas. Existing special packaged rations such as those used by the armed forces should be considered.

The desirable characteristics of a family food ration are listed:

1. The food products must be stable for at least 1 year under storage conditions of temperatures fluctuating from 0° to 95° F., and of relative humidity fluctuating from 10 to 90 percent.

2. The foods should be chosen for their general acceptability, for retention of their essential flavor and odor, and for other desirable characteristics under storage conditions.

3. The foods should be well-known types of food which the average housewife can use without detailed instructions.

4. At least a part, and preferably all, of the foods should not require cooking or heating.

5. None of the foods should provoke thirst, and they should require a minimum of water for preparation.

6. The ration should include fruit or vegetable juices to supply fluids when water may not be available.

7. The ration should supply about 2,000 calories per person per day. Detailed consideration of the vitamin, mineral, and protein content is not necessary, but the maximum utilization of natural food products is desirable.

8. All foods should be packaged in dust-proof, closed containers which can be rinsed externally with water, if necessary. Packaging materials should utilize noncritical items to the maximum possible extent.

9. The size, weight, and type of food package should be standardized for easy handling and efficient storage.

10. The foods selected should be items likely to be in good supply, even under conditions of nationally restricted food supplies.

11. The cost should be low.

Warehoused Food Stockpiles

Arrangements could be made for food wholesalers, jobbers, and distributors in suitable locations to increase their normal inventories of

specified food commodities to an extent that would partly or completely meet anticipated needs for emergency use. Since the food commodities specified would be those normally in commercial channels, and since the increased inventories of the wholesalers could rotate at fairly normal rates, problems of storage deterioration are avoided.

Inactive stores of food could be established in selected locations to be held for time of need. Special food stockpiles for civil defense use might contain individual units or family packaged rations in addition to bulk supplies for mass feeding operations.

The 11 recommendations listed for planning a family food ration also apply to inactive warehouse food supplies. However, under the first item mentioned—stability of foods—a storage life of more than one year is recommended. This can be achieved, in part, by more rigid control of storage conditions.

In the stockpiling of food for mass feeding operations, special consideration must be given to food items which require a minimum of preparation and which can be served easily and rapidly on a mass basis. Disorganization and confusion inevitably result in the first hours of an emergency. The simpler the plan for emergency feeding, the more easily it can be organized and put into prompt operation during these critical hours. Normal power and fuel may temporarily be unavailable, and water supplies may be limited.

The establishment of special inactive stockpiles of food offers the greatest challenge to nutritionists and technologists. In many instances, food items which would be desirable for stockpiling are not commercially produced in a form having optimal stability and acceptability characteristics. A more detailed assessment of the technological adequacy of currently available food items for stockpiling is being published (2).

Dehydrated fruits and vegetables, skim or whole dried milk powder, canned evaporated milk, dried eggs, certain types of canned meats, dried soup powder, canned fats, spreads, flour, sugar, cereals, fruit juices, and beverage products are types of food items which currently seem to offer the most promise for stockpiling purposes.

A careful plan would have to be devised for the management of any stockpiles of food to provide for periodic checking and rotating to prevent spoilage and waste. Storage bulk, ease of handling, and protection against rodents and insects should not be overlooked in planning stockpiles for mass feeding.

Special Feeding Problems

Lactating women, in particular, and infants under 1 year have nutritional needs which demand special consideration in the planning of food supplies (see Heseltine, page 872). Individuals with severe burns, fractures, and other major trauma require special nutritional treatment if maximum chances for recovery and speedy convalescence are to be assured (3). Dried eggs, dried whole or skim milk, crude casein, and dehydrated soups offer special promise as products which could be stocked as part of the general ration and which could be made

available in medical facilities to meet the special feeding requirements of the ill and the injured.

Special nutritional supplements—vitamin and mineral enriched food bars, wheat germ, brewer's yeast, tablets and capsules—are not required for civil defense emergency feeding of the homeless. Such products are, however, essential in certain types of major illness or injury. This need can be met by stocking the food supplements as part of medical supplies rather than in general food stocks.

New Sewage Projects

More than 2 million people will receive the benefits of new and improved service upon completion of 111 sewage treatment projects authorized during the first quarter of 1952 by municipalities in 33 States, according to figures released in June by the Public Health Service. New plants will be built in 72 instances, at a total cost of \$17 million. The other 39 contracts call for additions, enlargements, or replacement of existing plants, totaling an expenditure of \$10 million.

The Public Health Service cooperates in this work by developing comprehensive plans to abate water pollution and by providing research and technical assistance. The Water Pollution Control Act of 1948 authorized these services as well as financial aid in the form of grants to the States for investigations of water pollution caused by industrial wastes. The projects were developed through the cooperation of State and interstate water pollution control authorities.

Comparison with construction figures for the same months of previous years reveals that the present rate is less than the average for the years 1948-52. It meets only about one-fourth of the estimated needs arising from the growth of cities and industries.

Special Feeding Problems in an Emergency

By ROY E. BUTLER, M.D.

Much has been done to investigate the special feeding problems anticipated in a severe emergency, but much needs to be done before we are fully competent to handle them. In discussing special feeding problems, I have necessarily drawn heavily on the writings of others with more experience in these fields.

Those of us who have faced the crises of a severe emergency realize full well that previous plans are often abandoned. Instead of clock-work action, there ensues a period of frantic improvising, when available supplies and personnel are insufficient. However, plans are not wasted if they can serve as a framework for amended plans and thereby expedite a reasonable solution of the problems created by the violent disruption of normal activities. One uses what is available and hopes for the best.

Emergency Institutional Feeding

At the time of disaster, the dietary department of a hospital, and of other institutions as well, can provide prompt emergency food service to many casualties in addition to the patients, hospital staff, and volunteer workers (1).

It is essential that the hospital dietary department be represented on any over-all emergency planning committee for coordinating

dietary activities with other hospital services. There should also be a planning committee in the dietary department, composed of dietitians and representatives of the nonprofessional hospital staff and of the volunteers.

Detailed plans for an emergency food service would include menus to be served, items to be discontinued, kitchens to be used, foods to be stocked and requisitioned, measures for protecting food from contamination, details of the food service, personnel required and their duties, training of dietary staff for specific duties, instruction on water conservation and accident prevention, preparation of designated infant formulas, and space for each function.

Emergency planning for institutional feeding should also consider the preparation of one-dish meals from customary food supplies.

A useful exercise is to inventory hospital food supplies for any one day. Its usefulness can be increased by planning menus for a 3-day period, using the average population of the hospital, then doubling or tripling that number. Such a hypothetical problem may reveal the need for a limited stockpiling of necessary foods; one example—the supply of powdered skim milk may make the difference between an adequate and an inadequate diet.

Plans for personnel staffing are perhaps the most important item, inasmuch as adequate numbers of well-trained, dependable people will mean the difference in service between efficiency and chaos. A staff of well-trained members is the result of adequate planning and instruction. The staff should be able to function under fairly primitive conditions.

In cooking outdoors over improvised stoves, can the staff maintain sanitary conditions? Will they be alert to possible contamination?

Dr. Butler, a member of the health emergency planning staff in the Office of the Surgeon General, Public Health Service, prepared this material for presentation at the Combined Conference on Administrative and Scientific Aspects of Food in Civil Defense, held in London, November 26 to December 13, 1951 (see Public Health Reports, July 1952, p. 607).

Will they be aware of practicable correctives?

Staff training under simulated emergency conditions will point up areas in which there is lack of understanding and insufficient information.

Special Disaster Diets

Nutritional considerations are included in the therapy of burns, radiation damage, fractures, shock, and other trauma under emergency conditions.

Burns

As a basis for discussing nutrition in the therapy of burns, I have turned to the "Symposium on Burns" of the National Research Council (2).

Malnutrition frequently develops after severe burns. Prevention efforts should be instituted early and continued throughout the healing process. A coexisting anemia is associated with burns, which may be partly connected with an improper dietary intake. The treatment of a burn should be directed toward the rapid restoration of the normal anatomical structure.

Of probable importance to an individual's recovery following thermal burns is nitrogen metabolism. Severe burns result in significant nitrogen depletion. The loss of nitrogenous compounds depends upon the degree of the burn, the extent of burn, and the presence of infection. Nitrogenous products are lost from the surface of a burn. There is also an increased urinary excretion of nonprotein nitrogen, which begins a few days after the burn, reaches a maximum in 10 days, and lasts for several weeks.

The negative potassium balance, which is observed during the first few days after the burn, may be overcome by the oral administration of potassium. No relation exists apparently between the potassium depletion and the nitrogen depletion. The former is rapidly corrected while the latter lasts several days to a week or more.

Information is much more complete for sodium potassium and chloride depletion than for the other minerals.

Changes in the carbohydrate metabolism as manifested by hyperglycemia, lactic acidemia,

and lowered CO₂ (carbon dioxide) combining power are frequently observed following burns. These changes may last for several days and may result from gluconeogenesis and peripheral carbohydrate breakdown.

The vitamin requirements of patients with burns and their metabolism have not received adequate study. Some studies have been made of ascorbic acid, riboflavin, thiamine, and nicotinamide with respect to urinary excretion and load tests for saturation.

The dietary requirements for burn patients seem definitely to be higher than for normal patients. The diet should be well balanced, with adequate amounts of protein, carbohydrate, fat, minerals, and vitamins. Oral feeding of burn patients is preferable, but other methods may be used such as gastric, jejunal, and parenteral feedings, alone or combined. The optimum amounts for feeding have yet to be determined.

There is some lack of agreement about the time of beginning the higher intake of food. Some believe it should be delayed a day or two. Others believe it should be started as soon as possible. However, children were maintained in good nutritional condition following severe burns when they received from the beginning an intake one and one-half times the National Research Council optimal recommendations for normal children. Men who have been given 1.5 grams of protein and 45 calories per kilogram of body weight from the start showed some nutritional depletion. However, they showed less depletion than if the food intake had been started later.

Oral intakes at high levels are well tolerated when given soon after the burn. A delay of several days may be followed by gastrointestinal upsets. In such cases, continuous gastric drip feeding may be acceptable. If the intake levels are increased to 70 calories and 2 grams of protein per kilogram of body weight, continuous gastric feeding will not be tolerated by some adult patients.

Liquid diets with a reasonably acceptable mixture of the nutrients needed are considered practical for treating burned patients over long periods. Protein is provided in liquid diets through the liberal use of milk solids. Additional quantities of carbohydrates, fat, miner-

als, water, and vitamins will make a reasonably complete food. But the possibility of urinary calculi may be aggravated by the presence of calcium and phosphorus in large quantities of milk. Peanut butter has been suggested as a source of protein with a low calcium content.

Gavage feeding through an inlying gastric tube can be used wherever it is impossible, or inadvisable, to take food orally. Feedings of this type should be frequent at first and small in quantity, with a gradual increase in amounts over several days. The gastric tube may be left in place and removed only for weekly cleaning.

The drip apparatus may be used instead of feeding the liquid mixture in intermittent doses. Because of their high solubility and tolerance, hydrolyzed protein preparations are useful in gavage feeding. Tube feedings, either through small-caliber plastic tubing or rubber Levine tubes, may be continued for as long as 3 to 5 months. A liver protein preparation may be used because of its nutritional value and its low calcium content.

Fat supplies 20 percent of the calories in both tube and oral feedings. If fat absorption is impaired or faulty, an emulsifier such as Tween 80 or a finely homogenized oil may be added to the food.

Frederick J. Stare (2) has conducted studies on the intravenous and oral use of fat emulsions. He believes that the body uses the fat emulsion efficiently without side reactions. Coconut oil, with most of the particles less than a half micron, is mixed with a phosphatide preparation and a polyglycerol ester of oleic acid, as a costabilizer, to form the basis of the emulsion. Glucose and some water are added to give isotonicity to the emulsion. Stare has also studied the oral use of fat emulsions for increasing the caloric intake.

Radiation

In the event of radiation injuries, the diet should be a well-balanced one, rich in minerals and vitamins. To avoid the development of intestinal ulcers, it would be advisable to reduce roughage in the diet. There is little indication that such hematopoietic agents as folic acid and vitamin B₁₂ would be effective. Likewise, iron, or diets rich in iron, would seem useless until blood regeneration is observed.

Available data (2, 3) suggest that individuals in good nutritional status resist radiation injury better and that morbidity and mortality rates are lower for individuals whose nutritional states are maintained at high levels after injury.

The optimum caloric intake and the proper proportion of the nutrients needed has not been determined. If the patient has combined thermal and radiation injury, oral feeding may be difficult because of the gastrointestinal upsets which follow radiation injury.

The urinary output should be maintained by an adequate intake of fluids. The acid base equilibrium can be maintained by laboratory-controlled administration of electrolytes.

A nitrogen deficit may be relieved by amino acid preparations, hydrolyzed proteins, or protein-rich foods. Restricting the sodium chloride intake may assist in preventing edema.

Fractures

In fracture cases, the patient's diet should be adequate, and its caloric content should be consistent with energy expenditures. For many years, diets to expedite the healing of fractures have been debated. Some have favored a high calcium diet because it seemed logical that a greater calcium intake would be beneficial in the presence of lesions. Others have felt that vitamin D should supplement the diet. It can be said, however, that a sufficient amount of calcium or vitamin D is commonly supplied by adequate diets and sunshine. Nor is it thought that a fracture gives rise to increased requirements. Undoubtedly, there are other dietary factors given especial powers by some physicians. Malunion or un-united fractures are sometimes attributed to a faulty diet. Far more frequently, however, the fault lies in the failure to hold bone fragments in alinement.

The immobilization of a limb, or of an individual, may produce physiological difficulties. A leg or arm immobilized in traction or plaster without proper physiotherapy will show evidence of wasting of the soft parts and decalcification of bone. In leg fractures, it was found that disability was reduced by using pins to transfix bone fragments and by placing walking calipers in the plaster cast to permit free movement. When the fracture healed and the cast

was removed, the leg was found to be in better condition than those legs which had been immobilized in plaster for several weeks.

Individuals immobilized for fractures of the femur, it has been observed, are soon found to be in negative nitrogen balance. This condition apparently has no adverse effect on the healing of the fracture, but it may contribute to the weakness and debility which follow the inactivity attendant upon healing. That the negative balance can be changed to a positive nitrogen balance by sufficiently increasing the protein intake is a matter undergoing intensive study.

Shock

Shock is usually treated as a surgical or medical problem in which the therapeutic measures are well established. In an acute emergency there may be, however, shortages of blood, plasma or blood expanders, intravenous sets, and facilities for their use. The Public Health Service has found the oral administration of a salt solution to be of value in treating shock. A simple remedy, the solution uses familiar and readily available compounds: 1 level teaspoonful salt; one-half teaspoonful soda, and 1 quart water. Still the subject of study, and not a substitute for blood, the simple salt solution may temporarily tide an individual over until a transfusion can be given.

The National Research Council subcommittee on shock has recommended the manufacture of dextran as a blood expander in the treatment of shock. Dextran is thought to be well metabolized in the body and can be administered with relatively few side reactions. Other promising substances are under investigation.

Therapeutic Diets

Peptic Ulcer Patients

A regimen of frequent feedings of milk and cream for peptic ulcer patients would not be possible during the disruption of war. For their treatment these patients would find it necessary to depend upon antacids and coating substances. The danger of hemorrhage would not increase much with this course of action. Obviously, surgery should be reserved only for extreme cases.

Many ulcer patients, if not seriously ill, would want to assist in civil defense. They would be expected to eat whatever food was available. The enthusiasm of some ulcer patients for their civil defense duties might even lead to the complete disappearance of the ulcer symptoms.

Diabetic Patients

According to estimates, there are about one million known diabetic patients in the United States (4). As many again are believed to be undiscovered or not under medical care. About 70 percent of the known patients are taking insulin daily, a percentage which would undoubtedly be increased in an emergency: burns and other injuries would increase insulin requirements.

Patients who control their diabetic condition can serve usefully in civil defense or in industry. Complete understanding of their own disease and its treatment is their best safeguard.

For prompt recognition in an emergency, a diabetic patient should carry proper identification. To protect himself, he should also have a reserve stock of insulin sufficient to last a month or two, a simple test kit for glycosuria, and an extra insulin syringe and needles.

The education of the diabetic patient should be directed to the end that each one will be fully aware of the measures he must take before any emergency arises. He should know how to control his diabetes by diet alone if insulin is not available. Personnel with the task of feeding evacuees and casualties should receive rudimentary instructions on diets for diabetic patients. Such training applies more to personnel in emergency hospitals than to those in general hospitals where personnel and facilities for the proper handling of diabetes are likely to be present.

All diabetic diets should be nutritionally adequate. The diet most commonly used by physicians is one with protein (1 gram per kilogram), carbohydrate from 120 to 250 grams, and fat contributing 40 to 55 percent of the calories. In this diet protein meets all requirements. A pint of milk supplies the necessary calcium. Vitamin requirements are met without difficulty.

Another commonly used diet has fat supplying 20 to 25 percent of the calories; carbohydrate, 60 percent. With a diet supplying be-

tween 1,600 and 2,400 calories, the carbohydrate intake would amount to 240 to 380 grams a day.

There is a third type of diet which does not differ from a normal diet, where fat would contribute 35 percent, and carbohydrates, 50 percent of the calories.

Tuberculous Patients

In an emergency, the rich diet of the tuberculous patient must necessarily be restricted. During normal times, his diet would be high in calories and well balanced as to mineral and vitamin content, with emphasis on the protein component. Only an approximation of this diet may be available in an emergency, and the degree attained will depend on the food stocks at hand. Supplemental vitamins and minerals may bolster a diet otherwise lacking in these factors. For short-term emergencies, moderate to severe deprivation probably will not result in irreparable damage. Patients with fever will have an increased metabolism which will accentuate the need for additional food.

Conclusion

In general, I am in agreement with the philosophy of the Federal Civil Defense Administration as expressed in the manual on "Health Services and Special Weapons Defense" (5).

The Federal Civil Defense Administration

recognizes that special therapeutic menus need not be provided immediately after a major disaster. For experienced nutritionists and dietitians to be assigned at such a time to the procurement of special foods would be impracticable. Conditions for which special diets are usually prescribed could be controlled temporarily with drugs and medicines until an orderly flow of food supplies is re-established.

New Chief of Division of Dental Public Health

Dr. Thomas L. Hagan was appointed chief of the Public Health Service's Division of Dental Public Health in June 1952. He succeeds Dr. John W. Knutson, who was named chief dental officer of the Public Health Service.

Entering the Public Health Service in 1929, Dr. Hagan became a member of the commissioned corps in 1930. He has served as dental clinician in Public Health Service hospitals in Boston, New York, Pittsburgh, and Louisville, as dental consultant in regional offices in New Orleans and Atlanta, and since 1950, as assistant chief of the Division of Dental Public Health and dental consultant for Federal Security Agency Region III.

Dr. Hagan graduated from the Georgetown University Dental School and obtained a master's degree in public health at the University of Michigan.

Feeding of Mothers and Children Under Emergency Conditions

By MARJORIE M. HESELTINE, M.A.

Infants, children, and pregnant and lactating women, even though healthy and uninjured, are generally conceded to need special consideration under emergency conditions. They have heightened nutritional needs that cannot be met in full from the food allowance for the "normal consumer." Failure to meet these needs may have lasting consequences for the human resources of the Nation. Provision for dependents sustains the morale of heads of families who are working in essential industries and in civil defense.

Although the special problems associated with feeding these groups vary with the intensity and duration of the emergency, any plan for providing food under conditions of stress should meet at least three criteria.

Hunger must be allayed and physiological needs for maintenance of health and for normal growth should be met. The essential nutrients must be provided in a form and under conditions that avoid any danger to health through contamination, whether bacteriological, chemical, or radiological. Both the foods and conditions of feeding should help to minimize psychological trauma associated with the disaster

and, insofar as possible, should contribute to a sense of security.

These criteria shift in relative importance according to the specific age group in question and the severity and duration of the emergency.

Since the emphasis in civil defense food planning in the United States has been on an emergency period of less than 30 days, the problems associated with special groups for that period are given chief consideration in this discussion with but brief reference to a more prolonged state of abnormal food supplies and facilities. We have thought of this emergency as affecting a population which in the main has had enough food and consequently is in reasonably good nutritional condition. We have also assumed the existence of sufficient supplies of food to meet minimal emergency needs of normal consumers plus enough processed foods to supplement the diet of vulnerable groups for the immediate postdisaster period. A third assumption is that civilian food rationing is not in effect at the outset of the emergency.

Meeting Physiological Needs

The recommended dietary allowances of the National Research Council that apply to mothers and children provide the objective toward which emergency food plans should strive. Insofar as possible the needs for energy, protein, and thiamine of such especially vulnerable groups as children under 2 years and lactating women should be met even during short periods of emergency feeding. The recommended allowances of these nutrients amount to:

Miss Heseltine is chief of the nutrition section in the Division of Health Services, Children's Bureau, Social Security Administration. Her paper is based on material presented before the Combined Conferences on Administrative and Scientific Aspects of Food in Civil Defense held in London last winter (see Public Health Reports, July 1952, p. 607).

<i>Group</i>	<i>Calories</i>	<i>Protein (gm.)</i>	<i>Thiamine (mg.)</i>
Infants under 1 year-----	800	25	0.4
Children 1 to 2 years-----	1,200	40	.6
Lactating women-----	3,000	100	1.5

If these essential nutrients are eaten in the form of such foods as milk, bread, and potatoes, other vitamins and minerals will also be supplied in quantities that, added to those stored in the tissues of well-nourished individuals, will meet minimal requirements for a few days or even weeks.

Priorities Among Mothers and Children

During an acute emergency when it may be impossible to make special provision for all mothers and children, it is recommended that the first to receive attention be infants under 2 years of age and lactating women. For periods of less than a week, healthy and previously well-fed children over 2 and pregnant women should not suffer by subsisting on the food made available to the general population. For emergencies of more than a week, it is hoped that children between the ages of 2 and 6 years and women during the last half of pregnancy can be added to the groups receiving supplementary foods. During periods of prolonged food shortage, it is highly desirable that children of school age be added to the groups for which supplementary foods are provided, probably through meals served at school or in child care institutions. Although the special nutritional requirements of adolescents are recognized, it does not seem feasible to make special provision for them unless they are attending school or are engaged in an essential industry or civil defense work. Under these circumstances they can be supplied with at least one meal in addition to those eaten with the family.

Water and Milk

Water is the most essential of all nutrients, especially for infants. Pediatricians estimate that the daily allowance, including water used in the milk formula and in the cooking of cereal porridges, should be approximately 1 quart per day. An equal quantity of water as such or in beverages should meet the minimal needs of older children for drinking except in very hot

or dry climatic conditions. The infant's need for water as such is obviously made more acute by the general reliance on concentrated milks for infant formulas in the absence of ample safe supplies of fresh fluid milk. Provision of uncontaminated water therefore takes a top priority in child feeding programs. The household emergency shelf should provide ample supplies of potable water for dilution of the infant's milk mixture. If water is temporarily unavailable, other suitable fluids, such as bottled fruit beverages and mineral water, might be used in the formula.

A suitable source of energy to allay hunger and support activity and growth ranks next in importance to water. For infants under 2 years of age this means whole milk supplemented chiefly by cereals. The form of milk suggested for emergency child feeding in urban areas of the United States is evaporated (unsweetened condensed) milk, available in cans containing the equivalent of slightly less than 1 quart of fresh fluid milk. Practically all evaporated milk is fortified with vitamin D (chiefly in the form of 7-dehydrocholesterol) in the concentration of 400 international units to the reconstituted quart. Because this milk is widely used in infant feeding under normal conditions, it is a familiar and acceptable food. A daily allowance of one 14½-ounce can per child under 2 will allow for inevitable losses in preparation and for rejection of individual feedings by young infants. It will also compensate in part for shortages in other foods that are normally consumed by children from 1 to 2. If supplies of whole milk are not sufficient to provide the equivalent of 1 quart to all children under 2, infants under 6 months of age and nursing mothers should be taken care of first. Whatever is left could be prorated among the group between 6 months and 2 years.

As British experience in World War II has demonstrated convincingly, another form of milk that is satisfactory for emergency feeding, when safe water and facilities for reconstitution are available, is spray-dried whole milk. Preference should be given to those brands that are fortified with vitamin D. Four and one-half ounces of dried whole milk represent the solids in 1 quart of fresh whole milk.

Sugar is commonly added to infant formulas

of diluted whole milk as a supplementary source of energy. If uncontaminated sugar is not available, an equal quantity of a less dilute milk mixture will meet energy needs without causing digestive disturbances, provided that the milk has been modified by heat, as is evaporated milk, so that a finely divided curd is formed in the stomach. The baby, however, may indicate some displeasure at the absence of the familiar sweet taste in his feedings.

The usual practice of warming milk to body temperature before giving it to the infant may have to be abandoned in an emergency. Fortunately, there seems to be no evidence that bacteriologically safe unwarmed milk will cause digestive upsets.

In short, numerous adaptations to abnormal conditions can be made in providing milk without sacrifice of the infant's nutritional well-being.

For children over 2 and for pregnant and nursing mothers, skim milk can be used for part or all of their milk supply. The most readily available form of skim milk in American cities, nonfat dry milk solids, is well suited for emergency feeding if there is sufficient safe water and the necessary equipment for reconstituting the milk.

Other Foods

Cereal products will constitute the principal source of energy for mothers and older children and a supplementary source for infants. The cereal foods that are manufactured especially for babies, fortified as they are with minerals and vitamins and requiring only the addition of milk or water to make them ready to serve, are well suited for emergency conditions. Bread, which will probably be the main source of energy for the population as a whole, can be soaked to a suitable consistency for even very young children. When bread must constitute such a large part of the ration, it is important that it be of superior nutritive value—made of whole grain or enriched flour and containing a significant proportion of milk solids.

Other foods that are commonly given to children to supply vitamins, minerals, and additional protein and energy can be dispensed with in emergency feeding of not more than 1

month's duration. However, if supplies should be readily available, they will contribute appreciably to the nutritive value of the diet and to the peace of mind of mothers and children. American children under 2 normally consume large quantities of canned foods packed especially for their age—sieved or chopped fruits, vegetables, meat, and soup mixtures. These foods, which are packed in cans ranging from $3\frac{1}{2}$ to 5 or more ounces and are reasonably acceptable to the young palate even without the customary warming, lend themselves to emergency feeding schemes as a supplement to milk and bread or cereal. For emergencies of short duration, it is not felt to be necessary to supply vitamin or mineral supplements for children under 2 or for pregnant and lactating women. Enriched bread and whole-grain or restored cereals, together with milk, will take care of most of the B vitamins and of iron. The use of fortified evaporated milk will provide protection against rickets for most infants who consume the equivalent of a quart. During a prolonged emergency, young infants who take considerably less than 1 quart of milk per day should be given 400 units of supplemental vitamin D if at all possible. For such long emergencies, it is highly desirable to provide minimal quantities of ascorbic acid (25 milligrams per day) for infants, especially those fed exclusively on milk and cereals.

During the second half of pregnancy and lactation, adequate protein to support growth of the fetus or of the young child is highly desirable although under emergency conditions it is secondary in importance to meeting energy needs. An adequate supply of energy from such natural foods as lightly milled or fortified grain products, potatoes, and dried legumes (pulses) will not only contribute substantial quantities of protein but will insure the availability for tissue-building of whatever protein is provided from these foods or from milk.

To summarize, emergency nutritional needs of infants, young children, and pregnant and lactating women would probably be met by the following daily allowances:

For an emergency of even a few days' duration

1. Infants under 6 months: 1 large can ($14\frac{1}{2}$ ounces) evaporated milk, or $4\frac{1}{2}$ ounces dried whole milk, or 1 quart whole milk. Preference to be given to milk forti-

fied with 400 international units of vitamin D per quart.

2. Children from 6 months to 2 years: Same quantity of whole milk as for infants under 6 months plus enough staple foods to satisfy hunger from whatever is available for rest of family or group.

3. Lactating women: One quart of whole or skim milk or its equivalent in evaporated or dried milk, preferably fortified with 400 international units of vitamin D to the quart plus full food allowance for other adults.

For emergencies lasting more than 1 week

These additional groups should also be provided for:

1. Children from 2 to 6 years: At least 1 pint of whole or skim milk or its equivalent in evaporated or dried milk, preferably fortified with 400 international units of vitamin D to the quart plus staple foods to satisfy hunger.

2. Women during the last half of pregnancy: Same as for lactating women.

Protection Against Contamination

The usual hazards to infants and young children from contaminated water and milk are greatly increased under emergency conditions. Contamination from "peace-time bacteria" is likely to be the greatest threat since public water supplies may become polluted, facilities for sterilization by heat and for refrigeration nonexistent, and the job of preparing the food entrusted to inexperienced volunteers. In addition there are the potential dangers associated with atomic, biological, or chemical warfare.

Because water that has been made safe for general consumption by emergency treatment is believed suitable also for infants, those responsible for infant feeding under disaster conditions may well concentrate on techniques for formula preparation. Both the milk mixture and the container from which it is served should be free from contamination at the time of feeding. Experts in food sanitation can indicate safe emergency measures for sanitizing bottles and nipples when boiling water or steam is unobtainable. Terminal heating of the assembled unit—filled bottle with nipple in place and, if possible, protected by a nipple cap—should be employed whenever feasible. The time of sterilization in a boiling water bath should be the full 25 minutes currently recommended by the American Hospital Association for hospital formula rooms and by the Children's Bureau

for home use. In the household where refrigeration is unavailable, the bottles of sterilized formula should be left in the tightly covered container in which they were processed, removing only as many bottles as are needed for a feeding and replacing the cover on the kettle at once.

Bolstering Emotional Security

The foods given to young children and the conditions of emergency feeding have profound implications for their emotional reaction to a disaster. The experience of war-ravaged countries has proved how important it is that infants and young children be given familiar foods by familiar hands. As the British reports during the Combined Conference on Administrative and Scientific Aspects of Food in Civil Defense in London brought home repeatedly to those of us from overseas, emergency feeding is not necessarily mass feeding. Especially in the case of infants and young children, every measure should be taken to provide the necessary food within the accustomed setting of the family, the home, or the immediate neighborhood. The household that has a few days' supply of essential foods and fluids for young children on its emergency shelf and that knows how to improvise equipment for cooking and cleansing may not have to expose its most vulnerable members to the disturbing surroundings of an emergency feeding center. When mass care cannot be avoided, either in a temporary rest center or in the course of evacuation, the presence of a familiar figure, preferably the mother, will help to minimize the sense of insecurity. If breast feeding can be maintained under emergency conditions, both mother and infant will benefit. It is to give all possible encouragement to the lactating mother that special food allowances are recommended for her under emergency conditions even of short duration. Physiologically, it is of little consequence that her nutritive needs be met during an emergency of a few days' duration. Psychologically, she may profit greatly from the recognition of the contribution that she is making to the well-being of her baby and to society.

Ideas

Seeing Is Believing

CONNECTICUT. State restaurant inspectors recently introduced a modification in their swab-testing program. They streak a Petri dish of nutrient agar and leave it on the premises to incubate.

At the end of the 48 hours, they revisit the establishment. The food service personnel are asked to estimate the number of bacteria colonies. Then, the cover of the badly contaminated dish is removed, and the personnel are given a whiff of the obnoxious gases which have accumulated.

Such an olfactovisual demonstration is far more convincing to owners and food handlers than a mere

typewritten report of the number of colonies discovered by laboratory count. The State health department reports that it has had a veritable spate of requests for materials and methods to improve dishwashing procedures. So satisfactory has been the demonstration, the health department believes special classes for food handlers can be eliminated this year. Proprietors and food-service personnel alike have exhibited a sincere desire to improve the sanitary ratings of their establishments.

Community Evaluation

NEW JERSEY. The State health department has developed a survey or evaluation form for use by local citizen groups who are concerned about their local health situation—what it is—what is needed.

The citizens group fills out the survey form, requesting the assistance of the State health department

whenever necessary. The completed survey is analyzed in the State office. Then, a health planning team—State district health officer, public health engineer, supervising nurse, community health organizer, and statistician—will meet with the local group to explain the deficiencies found in the local service and ways of overcoming them.

Laboratory Suggestion

BROOKLYN, N. Y. Save purchasing capillary tubes—substitute a 4-inch metal needle for a capillary pipette in adding blood to the Wintrobe sedimentation rate tube. The needle should be long enough to reach to the bottom of the Wintrobe tube.

Glass capillary tubes may last only once, the laboratory of the Public Health Service Hospital at Manhattan Beach has discovered, but a steel needle will last indefinitely.

Immunization Drive Cartoons

LOS ANGELES, CALIF. For 3 years in a row, artist Bruce Russell of the *Los Angeles Times*, a Pulitzer prize-winning cartoonist, has contributed his gifted pen to the annual immunization drives of the Los Angeles health department.

Titled (reading from the left) "The Narrow Distance Between Two Points," "Two Birds, One Stone," and "Guardian Angel," one of the cartoons below appeared on the opening day of immunization in the public schools when wide-scale pub-

licity called the attention of parents to the need for immunization.

Immunization results showed the effectiveness of intensive newspaper, radio, and television publicity—each year's drive from 1949 through 1951 went over the goal.

Cancer Control in the United States

By RAYMOND F. KAISER, M.D.

The expanding attack on cancer has been sharply accelerated during the past 5 years by the efforts of public health agencies and other groups throughout the country to reduce mortality from this disease through early suspicion, accurate diagnosis, and effective treatment. These well-directed efforts at cancer control add a new and powerful force to basic and clinical research.

An upsweep of public interest following World War II contributed much to the establishment of cancer control programs. Even more vital have been the contributions of State health agencies, voluntary organizations, hospitals, universities and medical schools, and other institutions. Many of these groups have received Federal support under the cancer control program of the National Cancer Institute of the National Institutes of Health, Public Health Service.

The extent of the cancer problem makes clear why public health emphasis on cancer is strong. In relation to other diseases, cancer has advanced in the last 30 years from sixth to second place as a cause of death in the United States. It is responsible for more than 200,000 deaths a year and accounts for 14 percent of mortality from all causes.

Control programs are aimed at reducing cancer mortality: first, by finding ways to shorten the dangerous intervals between the onset of the disease and diagnosis, and between diagnosis and the start of treatment; and second, by improving cancer diagnosis and

clinical management. To these ends, real progress has been made since 1947 in developing programs of action throughout the country.

Today, official agencies in all the States, the District of Columbia, Alaska, Hawaii, Puerto Rico, and the Virgin Islands have cancer control programs. Thirty-three States and the District of Columbia are making specific appropriations for cancer control activities. In the District of Columbia and more than half the States and Territories, cancer has been made a reportable disease. Cancer teaching programs in almost all of the Nation's medical and dental schools have been strengthened. Postgraduate training of physicians in the field of cancer has been expanded, and educational programs for public health workers, general practitioners, dentists, and nurses have been started. Intensive public educational campaigns—notably those of the American Cancer Society and the National Cancer Institute—are under way, and substantial improvements have been made in the treatment facilities and diagnostic services reaching the individual citizen.

Increased Federal support has been an important factor in the accomplishments of the past 5 years. Up to July 1946, when Congress appropriated \$2,500,000 for cancer grants to the States, the Public Health Service had been able to assist State and community cancer control activities only through consultation services and funds amounting to less than \$250,000 a year. Since then, the National Cancer Institute has allotted \$17,300,000 in Public Health grants-in-aid for expansion of the cancer control programs of the States, the District of Columbia, Alaska, Hawaii, Puerto Rico, and the Virgin Islands. During this period \$14,815,000 has also been allotted in special grants-

Dr. Kaiser is chief of the control branch of the National Cancer Institute, National Institutes of Health, Public Health Service.

in-aid to institutions and individuals engaging in educational, research, and clinical projects dealing with cancer control. These allocations are made with the advice of a Cancer Control Committee of 12 members representing the American College of Surgeons, American Cancer Society, State health departments, hospitals, and medical schools.

Professional Education

Since the person with cancer is usually seen first by his family doctor, major cancer control emphasis is on programs designed to improve the diagnostic ability of the general practitioner. Such programs not only offer better professional education to undergraduates, graduates, and postgraduates, but also provide diagnostic and other special services to help the practicing physician.

So that oncoming general practitioners will be better prepared to meet the cancer problem, teaching grants totaling more than \$7,000,000 have been made to 79 medical schools to augment teaching staffs and to provide training materials (1).

Postgraduate training for physicians has also been emphasized. Clinical traineeships totaling about \$2,000,000 have assisted 450 young physicians, including 14 women, in taking advanced training in radiology, surgery, pathology, and other specialties. These physicians are established in practice or in positions where their special training benefits cancer patients.

In addition, many new aids to better cancer diagnosis and therapy are available to all physicians in general practice. The American Cancer Society and the National Cancer Institute have jointly produced a series of motion pictures on the problem of early diagnosis of cancer. A collection of slides assembled by the National Cancer Institute shows typical lesions and other aspects of the disease. Information on the progress of research, development of control techniques, and epidemio-statistical activities is available in printed form.

Thirty-nine of the Nation's dental schools have also used grants of funds to give students better grounding in cancer pathology, recognition of early lesions, and principles of cancer

Physicians add to their knowledge of cancer by taking part in meetings of hospital tumor boards. In the board meeting shown here a physician (standing) discusses a cancer patient with the director of the tumor clinic and other members of the tumor board while medical students look on.

diagnosis and treatment (2). An oral cancer exhibit and a set of projection slides showing oral cancer lesions have been made available to dentists throughout the country, and special cancer education programs for practicing dentists have been conducted by the State health departments of Idaho and Michigan.

Nurses and Cancer Control

The extent to which public health nurses and other registered nurses have been brought into cancer control accounts for much of the success of these programs. Regular courses in cancer nursing and cancer control are now taught at the University of Minnesota and Columbia University. Early in 1952 the Department of Nursing at Skidmore College, New York, and the School of Nursing at Boston University began pilot studies to develop better methods for teaching undergraduate nurses about cancer. For this they are using a monograph on "Cancer Nursing in the Basic Professional Nursing Curriculum—Suggested Content and Methods," provided by the National Cancer Institute. Another aid, "Cancer Nursing—A Manual for Public Health Nurses," produced by the New York State Department of Health

and the National Cancer Institute, is being widely used.

Cancer nursing seminars have been conducted in several States, Hawaii, and Puerto Rico, and a number of universities have offered concentrated, full-credit courses in cancer nursing.

Programs for Public Health Workers

The increasing public health problem of cancer is of special concern to health educators, medical social workers, statisticians, medical record librarians, and other public health personnel.

The Schools of Public Health at Yale, Harvard, and the University of Michigan have made use of grants-in-aid to establish courses in cancer control for public health workers. A number of cancer publications for public health workers have been prepared by various organizations during the last 3 years. The newest is "Cancer Control: A Manual for Public Health Officers," developed cooperatively by the New York State Department of Health and the National Cancer Institute, and soon to be published.

Pharmacists throughout the country became active in cancer control programs in 1948 through an educational campaign conducted by the American Pharmaceutical Association and the National Cancer Institute (3). During the year-long campaign, pharmacists in some 15,000 drug stores displayed counter cards to the public and posted bulletins in their prescription rooms giving information on the signs of early cancer.

Public Education

Effective measures for cancer control have their foundations largely in public education. Public and voluntary agencies in the cancer field have evolved programs of public information and education designed to enlist the cooperation of the layman by alerting him to the threat of cancer and guiding him to medical aid.

A timely example of public educational work is the nation-wide campaign to control breast cancer by urging women to adopt a simple procedure for monthly self-examination and to report to a physician any lump or other

abnormality discovered. State health departments, the American Cancer Society, the medical profession, and many other organizations have joined in a campaign to carry this message to the 32,000,000 American women 35 years of age and older. This is being done through showing a 15-minute motion picture, "Breast Self-Examination," jointly produced and distributed by the American Cancer Society and the National Cancer Institute.

The public learns about cancer from exhibits like this. Women's clubs and professional groups in the United States are using the exhibit shown above in the campaign to control breast cancer.

It is still too early to estimate the number of lives which may be saved by this campaign. However, a long-range study undertaken during 1951 in Iowa by the State Medical Society, the State Health Department, the Iowa Division of the American Cancer Society, and the National Cancer Institute is expected to provide basic data for a representative population of American women. Effectiveness of the film in teaching women how to examine their breasts has been indicated in a preliminary study made in New Haven by the Yale University Department of Public Health. This study found that 77 percent of the women who had not previously examined their breasts did so as a result of seeing the film (4).

Other instruments for public educational use have been developed. One especially suitable for high school and college students is the motion picture, "Challenge—Science Against

Cancer," sponsored by the Canadian Department of National Health and Welfare and the National Cancer Institute of the Public Health Service. The film points up the meaning in cancer research of new achievements in biology, physics, chemistry, and genetics.

Public educational work is also aided by a variety of pamphlets, leaflets, and other publications. Distribution of material of this kind in 1 year alone totaled 11,374,950 (5). These publications reach virtually all segments of the general population through activities of the American Cancer Society, the Public Health Service, State, county, and city public health departments, women's clubs and other organizations, and physicians in general practice.

Cancer Diagnostic Services

Striking increases and improvements in cancer diagnostic services and treatment facilities have been made since 1947 (6).

The number of approved cancer clinics grew from 407 in 1946 to 659 in 1951, stimulated by funds granted to the American College of Surgeons and State health departments.

Thirty States, the District of Columbia, Alaska, Hawaii, and Puerto Rico have added tissue diagnostic services to their cancer control programs. In Kentucky and Florida mobile cancer diagnostic units have been provided for rural patients.

Tumor registers and tissue-slide loan services, established at a number of universities, medical schools, and hospitals, have greatly improved training facilities for pathologists.

Studies to develop improved cancer therapy have also been conducted by universities, medical schools, and hospitals in various parts of the country.

Case-Finding Studies

Searchers for a practicable cancer case-finding method are exploring the possibilities of screening the general population by conventional clinical methods or of finding a suitable clinical test for cancer.

Although none of the diagnostic tests developed thus far has proved specific or sensitive enough to be of practical value, work in this

field continues. To develop new tests, a direct operational unit was set up at the University of Washington, Seattle, to work principally in the fields of immunology, enzyme chemistry, and blood proteins. Two national conferences have been held to review developments in the continuing search.

Cancer informational materials go abroad. Shown above are United States cancer magazines, books, pamphlets, and exhibits displayed in Paris at the Fifth International Cancer Congress, 1950.

The practicability of the cancer detection center as a case-finding device was studied during 1947 and 1948 by the National Cancer Institute through its operation of a cancer investigation center at Hot Springs, Ark. (7). The Hot Springs experience indicated that the detection center as such did not offer an economical, practical approach to the problem of controlling cancer. The study revealed that the vaginal cytologic test of Papanicolaou might be useful for screening the general female population. To obtain a group large enough for such screening, the center was moved to Memphis, Tenn. In general, most authorities feel at the present time that cancer detection centers have served a definite educational role for the profession, as well as the communities where they are located, by demonstrating the need for cancer clinic services in an area. The present tendency is to convert detection centers into cancer clinics.

Six cytology training centers are now in operation, one each at Cornell University, Tulane and Louisiana State Universities, and the Universities of California, Colorado, and Oregon.

Environment and Cancer

Environmental cancer-causing hazards and their control are subjects of intensive study. State health departments are conducting occupational and environmental cancer studies and surveys of selected industries in California, Colorado, Connecticut, New Jersey, Ohio, and Pennsylvania. Of special interest is the study of the exposure of workers and inhabitants on the Colorado plateau to radioactive substances in the uranium mining and processing industry. One completed occupational cancer survey in Ohio has yielded new facts and concepts on chromate cancer of the lung and associated health hazards. In a new project, the Ohio Department of Health is investigating possible cancer hazards to which workers in the rubber industry may become exposed.

Environmental cancer research units are also in operation at the Universities of Utah, Pittsburgh, and Southern California. The Utah unit is studying cancer hazards associated with the mining and milling of uranium ores and other radioactive materials. The Pittsburgh study deals with substances derived by high-temperature distillation of coal and coal tar products. The California group is investigating potential cancer-causing environmental hydrocarbons related to the petroleum industry.

Other work in this field is being done by the National Cancer Institute at its cancerigenic research laboratory established in 1949 at the Georgetown University Medical School in Washington, D. C. These investigators are studying environmental cancer-inciting agents in metals, environmental poisons, and synthetic oils.

Studies of Cancer Morbidity

Valuable new information on the size and nature of the cancer problem in the United States has been collected since the close of World War II.

New studies of cancer morbidity during 1947 covering 10 major metropolitan areas in the United States, first surveyed in 1937, have been completed by the National Cancer Institute. Individual reports have been published on the areas centering about San Francisco and Alameda Counties, Calif.; Atlanta, New Orleans, Denver, and Pittsburgh (see table); and, more recently, Chicago. Reports on Dallas, Detroit, Birmingham, and Philadelphia are in the process of publication.

These studies provide basic information on cancer incidence, prevalence, and mortality with regard to such factors as site, sex, age, and race. They re-emphasize the importance of

Incidence, prevalence, and mortality rates per 100,000 population for all cancers, 1947 and 1937, by sex

[Based upon data collected in Atlanta, San Francisco, New Orleans, Denver, and Pittsburgh, and adjusted on continental United States population, 1947.]

the various programs directed toward early case finding and early diagnosis.

Cancer in Human Experience

Much is being learned from cancer epidemiology, the study of cancer in human experience. Its immediate objective is to describe group characteristics associated with cancer and those associated with its absence, with the ultimate aim of explaining the natural history of cancer and thus provide a basis for prevention and control.

Physicians at Beilinson Hospital in Israel are studying the incidence of cancer of the uterine cervix, other female genital organs, and the breast among Hebrew women in Israel. The ethnic distribution of cancer in Hawaii is receiving special attention in epidemiological studies by the Territorial Department of Health. Epidemiologists at the University of Southern California are studying cancer of the uterine cervix. The Medical College of Georgia is conducting a one-county study of the incidence and control of cervical cancer by general population screening. Genetics of human cancer are being investigated by scientists at the University of Utah. Other cancer epidemiology studies are being conducted by the Maryland State Department of Health, the University of Cincinnati, Georgetown University, and Washington University.

Epidemiological records collected from cancer clinics in New York City, St. Louis, and New Orleans are being analyzed at the National Cancer Institute to test, on a large series of cases, a number of factors thought to have etiological significance in human cancer and to evaluate the further usefulness of this type of study in learning more about the etiology of human cancer. Among factors being studied are the relationship of fertility and marital status to cancer of the breast and cervix, and the relationship between smoking and cancer of the lung. The geographic distribution of leukemia in the United States is also being studied.

There Is Hope

How well are we getting at the control of cancer?

The question is partly answered by a recent report of the Metropolitan Life Insurance Company which stated: "Some encouraging signs are already evident in the postwar record of industrial policyholders. A comparison of death rates for 1946-47 and 1949-50 shows reductions in mortality from the malignant neoplasms among white females at ages 25 to 74 years. For the accessible sites as a group, both sexes experienced declines in mortality, white males by 2.4 percent and white females by 7.2 percent. Both sexes were favored with reductions in mortality for such specific sites as the stomach, the intestines and duodenum, the rectum and anus, the liver and biliary passages, and the bladder" (8).

Other signs of progress can be seen. The atmosphere of pessimism which has surrounded the cancer problem for so many years is being cleared away. Knowledge of etiological factors of cancer is increasing. Improved techniques for cancer therapy are numerous and varied. Programs and facilities for maximum discovery, early diagnosis, and adequate therapy have been created. These advances point to a progressive reduction in the death rates from cancer and to control of the disease.

Primary Isolation of *Brucella* From Human Blood Clots

By S. R. DAMON, Ph.D., DORIS BUNNELL, M.S., KATHLEEN GAY, B.S.,
and L. M. HUTCHINGS, D.V.M., Ph.D.

Clotted blood has been utilized by many laboratories as a dual-purpose type of specimen for aiding the physician in his differential diagnosis of brucellosis. The serum is used for the agglutination test, and the accompanying clot is cultured for the causative organism. Unfortunately, efforts at recovering *Brucella* from clots have not always proved productive.

In the bureau of laboratories of the Indiana State Board of Health, clot examination procedures were begun in the spring of 1946 as an adjunct to the seroagglutination test. Since that time more than 41,000 specimens have been examined serologically, and more than 10,000 of the accompanying clots cultured for *Brucella*. Experimentally, in vivo methods employing guinea pigs and embryonating eggs have at times supplemented the routine in vitro enrichment broth procedure.

Dr. Damon and Miss Gay are with the bureau of laboratories, Indiana State Board of Health, Indianapolis; Dr. Hutchings and Miss Bunnell are with the department of veterinary science, Purdue University, Lafayette.

The investigation was a joint study between members of the two departments, and was supported in part by a research grant from the Division of Research Grants and Fellowships of the National Institutes of Health, Public Health Service. The Communicable Disease Center of the Public Health Service provided funds in partial support of the guinea pig investigations conducted at Purdue University.

In conjunction with the Indiana brucellosis project, an opportunity was provided to study the over-all technique of clot culturing. Consequently, during the period of this study (1946-50, inclusive), efforts were directed toward improvement of procedures and the development of a more productive isolation method. This paper is a report of the experimental use of several different mediums in isolating *Brucella* from clots.

Isolation Procedures

Specimens employed in this study were clots from samples of human blood submitted routinely to the Indiana State Board of Health laboratories for one or more of the febrile agglutination tests. The serum from each clot was decanted and tested for *Brucella* agglutinins with a standardized *Brucella abortus* slide test antigen. If complete agglutination occurred in the 1:80 serum dilution, or in the latter part of the study at the 1:20 level, the clot was examined by at least two of the isolation procedures. Some clots from persons exhibiting no agglutinins, or only a low titer, were included because of the special significance of such clots.

With the exception of such divergences as will be noted, the following methods were employed throughout the project.

G-V Broth Enrichment

Approximately one-half of each clot was forced through a 5-ml. syringe, without the

needle, into crystal violet tryptose broth (C-V broth), made up as follows:

Tryptose (Bacto)-----	3.0 gm.
Dextrose (Bacto)-----	1.0 gm.
NaCl-----	.5 gm.
Thiamine HCl (Betalblon-Merck)---	.5 mg.
Distilled water-----	100.0 ml.
Agar (Difco, granular)-----	.1 gm.

The ingredients were dissolved in an Arnold sterilizer and when necessary the solution adjusted to a pH of 6.6 to 6.8 with 1 N NaOH. One-teenth milliliter of crystal violet dye (1:1,000 aqueous solution) was added and mixed thoroughly. The broth was dispensed in 10-ml. amounts and autoclaved 15 minutes at 115° C.

The clot and the broth were mixed thoroughly and incubated at 36° to 37° C. under an increased CO₂ atmosphere of approximately 10 percent. The blood clot-broth mixture was incubated one week and then subcultured to crystal violet tryptose agar plates (dye concentration 1:1,000,000). Three weekly subcultures were made from the broth before discarding it as negative. This method is further discussed in a report by Damon and Albright (1).

Guinea Pig Injection

The remaining half of the clot was forced through the syringe into 20 ml. plain tryptose broth (Difco dehydrated product), and about once a week the accumulated specimens were transported to the department of veterinary science, Purdue University. (These clot-broth mixtures were incubated under increased CO₂ tension until the time of shipment.) At the laboratory of the department of veterinary science, a 2-ml. aliquot of each of the specimens was injected subcutaneously into the groin region of each of two guinea pigs. These pairs of animals were maintained in separate cages, and quartered in a building separate from that housing the stock supply. A month following the injections, the pigs were autopsied. Samples of heart blood were collected for agglutination tests and the spleens were cultured for *Brucella*, since previous experience had shown the spleen to be the most consistent site of isolation. Each spleen was bisected and the exposed surfaces serrated before streaking onto a plain tryptose agar plate. The inoculated plates were incubated in an atmosphere of approximately 10 percent CO₂.

Yolk Sac Inoculation

The yolk sac inoculation technique, described in detail in another paper (2), consisted of injecting 0.5 ml. of comminuted blood clot-tryptose broth mixture into each of four embryonating White Leghorn eggs 3 to 5 days old. The injections were made with a syringe and 20-gauge needle directly into the yolk sac through a small opening in the large end of the eggs.

Typing of Cultures

For typing the species of *Brucella* recovered as above, both serologic and biochemical reactions were determined. Each isolated strain was checked for CO₂ growth requirements, ability to produce H₂S, and dye inhibition on basic fuchsin and thionin plates (dye concentration 1:100,000). Strain antigens were tested against known *Brucella* antisera.

Initial Use of Enrichment Broth and Guinea Pigs

Over a period of 3 years 1,698 human blood clots were examined both by guinea pig inoculation and by C-V broth enrichment as previously described. From these specimens 90 *Brucella* strains—61 *abortus*, 21 *swis* and 8 *melitensis*—were recovered, representing a 5.3 percent isolation.

In table 1, the 90 isolations have been tabulated as to the species and the method or methods of recovery. It is to be noted that only 26 of the 90 isolations, or 28.9 percent, were obtained by both broth enrichment and guinea pig inoculation of the same specimen. In other words, 64 *Brucella* strains, or 71.1 percent, were recovered by only one or the other of the techniques. This inconsistency appeared not to involve any one species.

From the foregoing results, it was evident that the two techniques for isolation were quite inconsistent in yielding duplicate recovery of *Brucella* strains. Although actually more recoveries were obtained from the C-V broth enrichment of the clots, the use of the guinea pigs added considerably to the total isolations.

As previously noted, that portion of the clot received by the guinea pigs was first inoculated into plain tryptose broth and held at 37° C. under increased CO₂ tension for several days

Table 1. Recovery of *Brucella* from C-V broth inoculated with clotted blood and from guinea pigs inoculated with clotted blood enriched in plain tryptose broth

Species	Guinea pig+ broth—	Guinea pig— broth+	Guinea pig+ broth+	Total recoveries from	
				Guinea pig	Broth
<i>Br. suis</i>	8	8	5	13	13
<i>Br. abortus</i>	16	28	17	33	45
<i>Br. melitensis</i>	2	2	4	6	6
Total.....	26	38	26	52	64
Percent isolations.....	28.9	42.2	28.9	57.8	71.1
Grand total=90 strains					

prior to injection. It seemed plausible that this preliminary enrichment of the inoculums might have been a determining factor in the incongruity of the results. The question then arose as to how efficient a medium of isolation the guinea pig would be if the clotted blood material were inoculated directly, following the same technique as before but excluding the initial enrichment of the clot.

The following experiment was then conducted in order to determine, if possible, the value of the guinea pig as an isolation medium when unenriched clotted blood was injected. Furthermore, since by this time an egg yolk sac inoculation technique was being used experimentally with some success, it seemed desirable to expand the study so as to compare this method with the guinea pig and C-V tryptose enrichment broth procedures.

Experimental Methods

The type of specimen was the same as previously employed, except that all clots from serums showing complete agglutination with the slide antigen at the 1:20 dilution level were included.

One-half of each clot was inoculated into C-V tryptose broth for enrichment and subcultured periodically as previously described. The other half was expelled through a syringe into a bottle containing 5 to 7 ml. of plain tryptose broth and small glass beads. The bottle was then shaken 3 minutes to further disintegrate the clot. This was the inoculum for the guinea pigs and for the embryonating

eggs whenever used. Duplicate guinea pigs were inoculated subcutaneously with 1.0 to 1.5 ml. of this mixture at the Indiana State Board of Health laboratories. Each pair was placed in a separate cage and the animals were transported to the veterinary research laboratory, Purdue University, where they were kept for 1 month before they were sacrificed for the examination. For a part of the experiment, 0.5 ml. of the same inoculum was injected concurrently into each of four embryonating White Leghorn eggs 3 to 5 days old, as already described.

Results

Over a period of 1½ years, 276 blood clots were examined for the presence of *Brucella* organisms. A total of 181 specimens was injected into both C-V tryptose broth and into guinea pigs; and 95 were examined by inoculating C-V tryptose broth, guinea pigs, and embryonating eggs as previously described.

Ten *Brucella* strains were isolated from the group of 181 specimens inoculated into guinea pigs and C-V broth. Two of the strains were recovered from the guinea pigs, whereas portions of the same specimens, following enrichment in the C-V broth, yielded 9 strains. One strain was isolated from both mediums. All recoveries were identified as *Br. abortus*.

From the 95 specimens examined by inoculation into the C-V broth, guinea pigs, and embryonating eggs, a total of 13 *Brucella* strains was recovered. The species and methods of isolation are tabulated in table 2. Twelve of the 13 strains were isolated via the embryo yolk sac technique. The guinea pigs yielded 1 strain

Table 2. Methods of recovery of *Brucella* (13 strains) from blood clots examined by injection into guinea pigs, C-V broth, and embryonating eggs

Species	Number of recoveries from		
	C-V broth	Guinea pig	Eggs
<i>Br. suis</i>	2	1	3
<i>Br. abortus</i>	4	0	8
<i>Br. melitensis</i>	0	0	1
Total.....	6	1	12

and the C-V broth 6 strains. The 1 strain which was not recovered from the eggs by the method employed was a *Br. suis* and was isolated from both the guinea pigs and the C-V broth.

The results of the entire study as reported in this paper are summarized in table 3, with a division of the data into three categories. The first group comprises the initial attempt at isolating *Brucella*, during which time that portion of the clot to be injected into guinea pigs received a preliminary broth enrichment. The second group is the experimental group, in which the guinea pigs were injected without prior enrichment of the specimens and concurrently with the inoculation of the C-V broth. The third group of data includes only those clots which were examined by injection into all three mediums—embryonating eggs, C-V tryptose broth, and guinea pigs.

The use of the three mediums as indicated

in the third group increased the total percentage of isolations from 5.3 to 13.6 percent. This increase was primarily due to the inclusion of the egg embryo technique. Statistically, there was no significant difference found in the percentage of isolations yielded by the C-V broth alone in any of the three categories. Likewise, in the first group, the difference in the percentage of isolations yielded by the C-V broth and by the guinea pigs was not found to be significant; however, in the second series, the opposite was true. The guinea pig technique was significantly inferior to the use of C-V broth in the isolation of *Brucella* from the blood clots.

In the third group of data only 95 specimens are included as being examined by all three methods. Although this number is not sufficient for a final statistical evaluation, it is obvious that a difference in the abilities of the three mediums to isolate *Brucella* does exist. Of the 13 recoveries from this group, only 1 is accredited to the guinea pig and less than half to the C-V broth. On the other hand, the embryonating eggs yielded all but 1 of these strains.

Of the guinea pigs injected, only the ones yielding an isolation had developed a titer. The remaining guinea pigs showed no evidence of agglutinins.

Discussion

The guinea pig, as employed in this study, appeared of little value in the primary isolation of *Brucella* from clotted blood material when the specimens were injected directly, without a preliminary enrichment. However, when the

Table 3. Summary of results of using different techniques for isolating *Brucella* from blood clots

		Inoculated into embryo yolk sacs.			12	1	12.6

blood inoculums were incubated in tryptose enrichment broth for several days prior to injection, different results were obtained. In the former instance *Brucella* was recovered from only 1.1 percent of the specimens; under the latter conditions the organism was recovered from 3.1 percent. It is believed that the number of organisms in the inoculums, rather than increased resistance of the guinea pig stock to *Brucella* infection, was a principal factor in the differing results obtained during these two phases of the investigation. This guinea pig stock was also being currently employed in other experiments, and there was never an indication that the animals might have suddenly developed an immunity to *Brucella* infection.

Of the in vivo methods, which involved the injection of both unenriched and enriched clots into guinea pigs, and of unenriched clots into embryonating eggs, the latter procedure gave the highest percentage of recoveries from the clots examined and has to date appeared superior to the in vitro C-V tryptose enrichment broth technique.

From the 1,974 specimens included in this study, 113 (5.7 percent) recoveries were made. This proportion is much higher than that reported by West and Borman (3) when clots from all specimens submitted for agglutination tests were cultured, including those from negative serums. It is lower than the total percentage of recoveries made in the laboratories of the Georgia Department of Public Health (4) when special blood culture outfits were used for collecting specimens from persons exhibiting agglutination titers of at least 1:320 in order to supplement clot culturing. However, based on the limited number of clots injected into embryonating eggs, this medium yielded as high a percentage of isolations as the Georgia laboratories obtained with their special supplementary specimens.

The culturing of all clots routinely, without regard to titers of the accompanying serums or symptomatology of patients, has not proved very profitable in this laboratory. From 7,906 unselected clots, only 0.3 percent isolations were

obtained, with only two recoveries from specimens with negative agglutination titers (1). In conclusion, clot examinations in the bureau of laboratories of the Indiana State Board of Health have been quite profitable when clots were selected from specimens with an agglutination titer of at least 1:40, and especially when these clots were injected into embryonating eggs.

Summary

During 4½ years, three basic techniques for the isolation of *Brucella* from human blood clots—employing guinea pigs, a crystal violet tryptose enrichment broth, and embryonating chick eggs—were studied.

Altogether, 1,974 specimens were examined and 113 *Brucella* strains were recovered: 79 *Br. abortus*, 9 *Br. melitensis*, and 25 *Br. suis*.

It was found that the incubation of portions of the blood clots in tryptose broth for several days before injecting them into guinea pigs apparently accounted for most of the isolations obtained from guinea pigs. Injection of clotted blood directly into these animals yielded very few isolations. Of the three methods of isolation, the guinea pig proved the least efficient and the egg inoculation technique yielded the largest percentage of recoveries.

thus becomes a question of the feasibility of changing the factors, or, in its simplest terms, of how much it costs in time and money to change B or the slopes of P or C. This cost is determined by local conditions for each species and is naturally extremely variable. It is hard to change the slope of C, because this implies changing the inherent psychology of the species. Therefore, only environment (B) and predation (P) remain to work with.

Predation Intensity

Clearly, a sufficient increase of rate of predation will reduce the population. Existing data help to indicate how much increase in predation is sufficient. For insects there is considerable evidence that predation can be increased under some conditions (13), but for vertebrates there is little evidence that natural predators or disease hold a population below the level determined by density-independent factors. For example, Errington (4) found no increase in rate of mortality from predation in many species. These data show that under usual conditions the predators are well adjusted to their prey and have little effect on the numbers. Indeed, even intensive hunting did not reduce pheasants in Michigan (1). But these cases are at one end of a scale of intensities. The slope of the predation rate can be any value from 0 to 1—no predation to complete predation (right-hand diagram, fig. 1). Krumholz (5) found that *Gambusia* clearly limit the population of mosquito larvae. Russell (11) summarized the obvious effects of excessive fishing on supplies of commercial fish. Rothschild (9) quotes many cases of extermination of birds by cats, dogs, and rats on islands.

Thus, there is a continuous series of examples from no effect to complete extermination. It is even possible that predation is not intense enough for maximum population. Swingle and Smith (14) showed that increased fishing was desirable to increase the yield from farm ponds in Alabama, while Lynch and associates (8) found that intensive trapping of muskrats was necessary to prevent the muskrats from increasing so greatly that they destroy their habitat.

Although predation may occur at any inten-

Figure 2. Changes in rat population in blocks in Baltimore after poisoning with compound 42 (warfarin). In the smallest block (A) the greatest decline (96 percent) was obtained and the slowest subsequent increase. In block B a good reduction (85 percent) resulted. In the largest block (C) a fair reduction (69 percent) was followed by a rapid return to the original number.

sity, the practical problem is how to attain the proper intensity of predation in a given circumstance. Whether the result is a trivial effect or extermination depends upon the effort expended. In actual practice the effort ex-

pended is rarely enough to reduce the population to a satisfactory level. Poisoning and trapping, for instance, have as yet been unable to reduce rats to the low level desired by the health officer. Poisons and traps can reduce rats enough to satisfy the farmer and some householders, but that is a question of sanitation standards.

Change in Reproduction

The converse of a change in mortality is, of course, a change in reproduction. The upper horizontal line in figure 1 represents rate of reproduction, which is assumed to be constant, although it probably is concave downwards. If reproduction is increased from R_1 to R_2 and the slopes of the predation and competition lines are not changed, the population will obviously increase. Reproduction can be increased in several ways: (a) some heredity mechanism; (b) increased food and shelter; and (c) artificial introductions of young or adult individuals. The first is outside the scope of this discussion since we are assuming a given species. The second is obvious: more food and shelter mean more reproduction. The third is a favorite panacea of sportsmen for all hunting troubles. Although it is possible to raise game or fish and release them in areas where sportsmen can get them, this system soon degenerates into the notorious "put-and-take" scheme in which the game commission dumps trout into the stream a few yards away from the fishermen who catch them.

The problem of stocking fish and game, like predation, is a question of intensity. Examples can be cited for the whole gamut of results from trivial effect to satisfactory solution. But as a practical problem of dollars and cents, stocking rarely is effective at a level that the sportsmen will support by taxes or fees. Buechner (3) showed that success was seldom attained with quail. Fish hatcheries have limited value for the improvement of fishing (10). But stocking has a place. Baumgartner (2) showed that the stocking of quail was beneficial in low populations but not in high populations. Krumholz (6) discusses the obvious conclusion that stocking newly constructed farm ponds is beneficial. Unfortunately, for higher verte-

brates the predation + competition line rises very steeply at high populations, and hence great expense is required to increase the population by stocking methods. Thus, as in predation, a problem of practicability confronts the investigator.

Predation Results

What are the practical means at our disposal for changing the population? It is clear that an increase in predation (the slope of line P, fig. 1) will reduce the population. This increase can be obtained for a sum of money that may or may not be available, depending upon conditions. But increase of predation also reduces competition and thereby makes conditions better for the survivors. Thus, the increase of predation is partially opposed by a reduction in competition.

Figure 3. Results of three levels of intensity of environmental control of rats in blocks in Baltimore. The "rehabilitation block" was greatly improved. The "police block" was partially improved. The "reference block" was not changed until January 1950 (S). The reduction in rat population is proportional to the intensity of rehabilitation.

In contrast, an increase of B (mortality due to environment) will reduce the population more effectively because B is increased by reducing the food and shelter. These measures, however, have additional effects. The rate of reproduction is decreased and the slope of the rate of predation is increased.

Conversely, a decrease of B will increase a species. These changes in turn also increase the rate of reproduction and decrease the rate of predation. Thus, this management procedure has three means of action.

The results of predation can be compared directly for rat populations in three blocks in Baltimore. Figure 2 shows the history of rat populations in three blocks in which compound 42 (warfarin) was used by a highly competent technician. The percentage reduction was greatest in the block with the smallest population, and also the increase was least in the block with the smallest population. These three populations show the points emphasized above. Predation can be intense enough to be satisfactory in some blocks (A), but it is often unsatisfactory (C). The question is simply how frequently the reduction in A can be accomplished. Unfortunately, budgets are a limiting factor in such accomplishments.

Housing Improvements Effective

Contrasted with poisoning is the rat reduction resulting from improved housing and sanitation in blocks rehabilitated by the Baltimore City Health Department (fig. 3). The "rehabilitation block" was inspected by the health department in April 1948, and the rat population was eventually exterminated. The "police block" was inspected by the police, who do less intensive work. The "reference block" was not affected until January 1950, when sanitation (S) was begun. The difference in results in the poisoning experiments needs no comment, but the costs do. The only cost of rehabilitation to the taxpayer was for inspection and enforcement. The actual sanitation was performed by the tenants and landlords. No figures on cost per premise are available, but the cost must be divided according to the benefits in all aspects of housing because the rehabilitation consisted of improving the construction, repairing the

floors, cementing the cellar, correcting the plumbing, cleaning the yard, and similar improvements. If we assume the average cost is about \$50 and that the actual rat work is one-fifth of the total, then the rat control is \$10 divided between tenant and landlord. This multiple benefit aspect is extremely important. Few cities would advocate a rat control program at \$50 a premise, but many would at \$10 a premise.

Summary

This discussion has emphasized the problem of intensities and interrelations. Rat control is simply a problem of increasing the mortality rates. A perspective derived from comparison of other species shows clearly that a change in the environment gives the most results for the money spent. But in some cases, for economic or cultural reasons, the expenditure of even moderate sums is impossible. In these areas the cost of temporary poisoning jobs must be met until adequate improvements in conditions can do a real job.

The simple objective of getting rid of rats is too narrow to merit the attention of health officers. The worthy objective is to improve living conditions so that a variety of diseases and pests will disappear and a better community will result.

New Aid For Venereal Disease Nursing

In response to inquiries by public health nursing educators about the nurse's responsibility in the changing pattern of venereal disease control, the Public Health Service, through the Division of Venereal Disease Control in the Bureau of State Services, cooperated with the Georgia State Department of Health in holding a 2-week work conference early in 1951 at the Alto Medical Center, Alto, Ga. Sixteen States and 23 universities were represented by faculty members attending the conference.

An outgrowth of the conference is the publication of a 28-page "Suggested Outline for the Teaching of Venereal Disease Control," by the National League of Nursing Education, 2 Park Avenue, New York 16, N. Y. Divided into three major units, the outline covers: medical aspects of venereal disease; venereal disease within the framework of nursing; and community education in venereal disease.

The outline is planned to serve as groundwork for revising courses of instruction for the student nurse in venereal disease control. Its use will depend on the individual instructor, the needs and interests of the students, available resources, the scope of the curriculum, and the area where the school of nursing is located. Methods and activities are suggested to the instructor for selecting realistic activities in the development of learning situations.

The Practical Management of the Recalcitrant Tuberculous Patient

By CEDRIC NORTHROP, M.D., JOHN H. FOUNTAIN, M.D.,
and DANIEL W. ZAHN, M.D.

Prevention of the development of recalcitrance is the logical beginning of practical management of tuberculous patients who fail to follow medical recommendations. Several steps can be taken to assist in lessening the uncooperative behavior of these patients.

Sanatorium Care

The first step in the prevention of recalcitrance is to have enough sanatorium beds available for the immediate care of all persons who have active tuberculosis. These beds should be located in reasonably attractive, conveniently located sanatoriums, staffed by competent and sympathetic personnel. To direct any great effort toward coercion of the uncooperative patient when there are cooperative patients awaiting hospitalization seems to be a questionable procedure.

Waiting lists for sanatorium care were abolished in Washington in 1948. As a result of

building programs in Spokane, Yakima, and Tacoma, plus the acquisition of a surplus military hospital in Seattle, 2,400 beds, exclusive of those in Federal and mental institutions, are now available for the care of Washington tuberculosis patients. This number, divided by the 310 tuberculosis deaths of Washington residents (provisional data for 1951), establishes a ratio of 7.7 available beds per annual death. The average number of patients hospitalized in 1951 was 2,100—a ratio of 6.7 patients per annual death.

Patient Orientation

Adequate indoctrination of the patient prior to admission to a sanatorium is also fundamental. The physician who makes the diagnosis of tuberculosis and refers the patient for sanatorium care will need to take the time to explain skillfully and in simple language the significance of the patient's individual tuberculosis problem and the steps he must take both to get well and to protect his family and his community. The assistance of public health nurses and medical social workers is valuable to reinforce this preliminary indoctrination.

However, a physician cannot delegate his full responsibilities to his assistants. He himself must start the education of the patient. Following preliminary discussion of the medical facts by the patient and his physician, the clinician refers the patient to the medical social service department and the public health nurse.

Dr. Northrop is tuberculosis control officer, Washington State Department of Health; Dr. Fountain is director of the division of tuberculosis control, Seattle City-King County Department of Public Health; and Dr. Zahn is chief of the medical service at Firland Sanatorium, Seattle, Wash. This paper was presented before the forty-eighth annual meeting of the National Tuberculosis Association, Boston, May 27, 1952.

for further help. The support of the family, the care of the children or of the farm, and many other problems are reviewed and careful plans are made to meet the various situations that will arise during sanatorium treatment.

In many areas in the United States, the financial eligibility provisions written into the tuberculosis control law are stumbling blocks to sanatorium placement. The Washington statute states simply that the arrangements for hospital care for tuberculous patients shall be the responsibility of the jurisdictional health officer, and this officer shall also have responsibility for determining the financial eligibility of patients admitted to tuberculosis hospitals. Since no standards for admission are written into the law, the health officer may concentrate on the epidemiological implications of the case rather than consider primarily the fiscal aspects. In other words, tuberculosis hospitalization becomes a part of a communicable disease control program rather than a component of medical care for the indigent. To the best of our knowledge, no tuberculosis patient needing sanatorium care in our State is staying at home because of financial obstacles.

Prevention in the Sanatorium

The next step in preventing the development of uncooperative patients takes place in the sanatorium. An interested, sympathetic medical staff, sufficient in number, is necessary. At Firland Sanatorium, Seattle, there is a staff of 19 full-time physicians to serve the 1,058 patients now in residence—55 resident patients per physician. This number of physicians is exclusive of interns, residents, pathologists, surgeons, or of the many part-time consultants. The medical staff is supplemented by five auxiliary services: education, occupational therapy, recreation, vocational guidance, and medical social service.

Irregular Discharges

In spite of adequate facilities for their care, many tuberculous patients refuse to enter the sanatorium, and a considerable number of those who do enter become irregular discharges (against medical advice, absent without leave,

disciplinary). At Firland these irregular discharges constituted 47 percent of all discharges (exclusive of deaths) in 1948; 44 percent in 1950; 37 percent in 1951; and 36 percent the first 4 months of 1952.

In 1949 Drolet and Porter (1) reported a detailed study of patients discharged in 1947 from tuberculosis institutions serving the New York metropolitan area. Of 1,413 discharges (deaths excluded), 731 (52 percent) were irregular. Apparently, this problem is severe in other seaport cities besides Seattle.

Analysis of the irregularly discharged patients at Firland Sanatorium in 1950 shows that 29 percent were alcoholics, 8 percent had obvious psychiatric difficulties, and 9 percent had records of jail sentences. In spite of the availability of adequate sanatorium care, slightly more than one-third of the discharges (other than patients who died) have been without medical approval. The magnitude of the problem has been recognized by health authorities, and some steps have been taken to reduce it.

Legal Authority

The first step was to strengthen the authority of the health officer in handling the uncooperative patient with communicable tuberculosis. The Washington law (Remington's Revised Statutes, sec. 6094, enacted in 1903) states in part: ". . . Every health officer shall have the power to remove to and restrain in a pest-house or isolation hospital, or to quarantine or isolate, any person sick with any dangerous, contagious, or infectious disease until such sick person shall have thoroughly recovered."

To define the power of the health officer further, on December 4, 1948, the Washington State Board of Health adopted the following regulation on pulmonary tuberculosis:

Isolation. Of such active cases as do not observe the precautions to prevent the spread of the disease. The place of isolation to be in such quarters as designated appropriate by the jurisdictional health officer, and for such time as necessary until one of the following conditions is fulfilled: (1) The patient's pulmonary disease is considered to be "apparently arrested" (National Tuberculosis Association Classification—1940); (2) the patient agrees to accept routine sanatorium care; (3) the patient dies; (4) other arrangements for adequate isolation are made, which,

in the opinion of the jurisdictional health officer, protect the public from the spread of his infection.

Quarantine. Whenever, in the opinion of the jurisdictional health officer, he deems it necessary in the interest of the protection of the public, in uncooperative cases who refuse to observe precautions recognized as necessary to prevent the spread of this disease, quarantine procedures should be employed in accordance with the provisions under "isolation."

The deputy prosecuting attorney of King County was exceedingly helpful in specifying to the health officer the exact steps to be followed to conform to the principles of sound legal procedure. The first isolation order was issued by the King County Health Department on October 7, 1948; the first court order of commitment in King County for violation of an isolation order was issued February 4, 1949.

Locked Ward

As the compulsory isolation procedure was applied, it became apparent that a locked ward was necessary to handle the difficult individuals at Firland. Such a ward, of 27 beds, was made available at the sanatorium June 21, 1949.

The usual practice has been to keep the patient in the locked ward for 2 weeks after admission, and then transfer him to the regular wards of the hospital, the length of his stay there to depend on good behavior. If he disregards the institutional rules, gets drunk, or leaves the sanatorium, he is subject to reassignment to the locked ward for a longer time. Because of the admission of a few intractable patients, several of whom tried to set the ward on fire, experienced officials of the Seattle city police and fire departments were consulted. These officials helped to promulgate security regulations for safer operation of the locked ward.

Once the locked ward had been established and the procedure for its use simplified, the number of patients under isolation order increased markedly. As of May 15, 1952, there were 118 persons at Firland under isolation order, 12 in the locked ward and 106 in regular wards with the same privileges as other patients, except that if they violate hospital rules or run away, back to the locked ward they go. Men patients requiring isolation predominate in the ratio of 5 to 1. Four other sanatoriums in

Washington have set up locked wards varying in size from two to nine beds.

As the result of having adequate sanatorium facilities available, many of the small and medium-sized counties do not have one case of active tuberculosis known to the local health department in which the patient is staying at home against the recommendation of the health officer.

Emotional Problems

It was apparent by 1948 that many of the patients who were irregularly discharged had emotional problems of varying intensity, some of them frank psychoses. The development of the auxiliary services—education, occupational therapy, recreation, vocational guidance, and medical social service—is a constructive step forward. These services are helpful in creating a successful adjustment to sanatorium life for many patients.

However, they are not enough. There remains a group of patients unable or unwilling to comprehend the benefits of the sanatorium care provided for them. We have undertaken several services in an attempt to meet these needs. One of the first steps was the formation of a chapter of Alcoholics Anonymous, with regular meetings in the sanatorium. The first meeting was held September 20, 1950, and meetings have continued, with an average attendance of approximately 20 members.

We hope that the provision of psychiatric consultation may help to combat irregular discharges. In cooperation with the University of Washington Medical School, psychiatric consultation services were expanded in 1949. Based on 2 years of experience, the consulting psychiatrist has formed some ideas on the management of maladjusted sanatorium patients, among whom alcoholics predominate.

Participation in Alcoholics Anonymous is very useful for the patients with mild to moderate maladjustment and can successfully tide many of them through their period of rest regimen. For the severe alcoholic, psychotherapy is difficult and often hopeless. Compulsory isolation and segregation are necessary if the patient and his community are to be protected. Some psychiatrists have maintained

that this forcible isolation of recalcitrant tuberculous patients would create a group of bitter and highly antagonistic people. Our experience indicates that most of the patients isolated under compulsory quarantine have proved to be tractable and capable of being managed successfully, once they learn that they can be restrained successfully if they fail to cooperate.

One of the most valuable byproducts of the psychiatric consultation service is the education of the sanatorium medical staff on day-to-day evaluation and management of adjustment problems of patients. The value of this service cannot be overemphasized.

X-raying Jail Population

Edwards and Reisner (2) reported in 1940 on the value of X-raying the jail population in New York City. In Washington several partial surveys were done in jails and one fairly complete, continuous survey in the Spokane County jail, which is located close to the health department, where miniature film equipment was available.

An X-ray machine was installed in the county jail in Seattle in June 1951 for routine X-raying of prisoners on admission. The group having the largest number of active cases was made up of the prisoners being sent to the county farm for rehabilitation of alcoholics. Of the 510 prisoners in this group, 88 (17.2 percent) were found to have active tuberculosis.

Case-finding efforts in jails are very lucrative in terms of cases found per amount of money spent. However, they do make absolutely necessary the provision of a locked ward for the prisoners discovered to have active tuberculosis. A prisoner may be sent to the sanatorium while awaiting trial or, if he has been tried and found guilty, the judge may suspend sentence provided the prisoner goes to the sanatorium for treatment. If the security facilities of the sanatorium locked ward are not adequate, there are single rooms in the county jail and a tuberculosis ward in the State penitentiary at Walla Walla.

Management Possible

Much experience has been gained during the past 3 years concerning the recalcitrant tuber-

culosis patient and his management. Among the large number of recalcitrant individuals handled during this period, the Seattle City-King County Health Department has had to secure only 16 warrants for the arrest of individual patients. Only 12, plus 2 repeaters, have been tried in court; all others have been handled through health department isolation regulations. The last instance in which it was necessary to go to court was on January 17, 1951—manifestation of the fact that the local health department and the sanatorium are now "on top of the problem" and the group of individuals who are headstrong or distorted in their thinking can be handled successfully.

If the ultimate objective of wiping out tuberculosis is ever attained, it will be necessary for every metropolitan area to seek cases "on the other side of the tracks," and for every city to have a case-finding program in jails, prisons, and the flophouse district. In consequence it will be mandatory to set up in every city a facility for the detention of this type of patient. The epidemiological benefits will justify all the trouble; the expense is modest.

It is true that in the first 4 months of 1952 the irregular discharges still constituted 36 percent of all discharges (exclusive of deaths) from Firland. However, most of these patients were individuals who had progressed with their treatment to the point where they were ambulatory or semiambulatory, and merely left the sanatorium before fulfilling the recommended standard of 4 hours of work tolerance for 3 months. The health department usually rounds up fairly promptly patients who are sputum-positive and constitute a definite public health menace. These patients immediately return to the sanatorium or are sent back under a health department isolation order.

In King County (population 760,000), on May 20, 1952, three patients with active, communicable tuberculosis were known by the health department to be at home contrary to the wishes of the department. An additional 60 patients with communicable tuberculosis were at home, but their cooperation with the health department and their circumstances were such that they were not considered a public health menace. None was working and none had children at home.

Summary

1. The practical management of the recalcitrant tuberculous patient begins with prevention of uncooperative behavior. Especially important is sanatorium care that is adequate both quantitatively and qualitatively.

2. The more nearly complete the job of tuberculosis control becomes, the higher the percentage of patients who are difficult to manage.

3. To solve the problem of the recalcitrant tuberculous patient two things are needed: (a) adequate laws requiring isolation of the patient; (b) a place for forcible isolation, preferably where treatment can be given.

4. Of the 1,058 patients now at Firland Sanatorium in Seattle, Wash., 118 (11 percent) are under isolation order. Forcible isolation of these patients has not developed a group of bitter, antagonistic individuals; most of them become tractable and readily manageable.

Rabies Conference

The South Middle Atlantic Regional Rabies Conference, attended by delegates from Pennsylvania, Ohio, Maryland, Delaware, Virginia, West Virginia, Tennessee, Kentucky, North Carolina, South Carolina, Georgia, and the District of Columbia, was held June 2-3 in Washington, D. C. Among the recommendations made were these: Each State should establish a rabies control program to be carried out through a committee composed of representatives from State agencies; provisions should be made for exchange of rabies control information between States; and each State should arrange for the prompt reporting of rabies cases in all animals.

The conference, called by the Public Health Service staff of the Region III office of the Federal Security Agency and co-sponsored by the Fish and Wildlife Service of the Interior Department and the Bureau of Animal Industry of the Department of Agriculture, stressed the need for dog immunization clinics and for the control of stray dogs. It called attention to the increase of rabies in the wildlife in this area, particularly in foxes and skunks, and the increased dangers of infection in cattle and such domestic animals as cats and dogs.

An Eastern Regional Rabies Council, a continuing body representing the States which took part in the conference, was established to develop plans and procedures to put the recommendations into effect.

Swimming Pool Classification Program In West Virginia

By ROBERT S. JACOBSON, B.S.

The division of sanitary engineering of the West Virginia State Department of Health is now completing the second year of work on a proposed system of swimming pool classification. The trial program, started in the summer of 1950 and continued in 1951 with only minor changes, will continue during 1952. Personnel limitations, Government building restrictions, and material shortages have prevented the program from being established as rapidly as was originally planned.

For the past 25 years, it has been a requirement in West Virginia that all new pool construction be approved by the State health department, and compliance with this requirement has resulted in reasonably good installations. The State health department has also made it a practice to visit some of the pools during the year, and, through the cooperation of sanitarians from local health departments, to have more or less regular bacteriological sampling of the majority of the pools. Although this irregular coverage was of considerable benefit, many substandard pools continued in operation. The less desirable pools were generally quite old, dating back as far as 40 years. But it was not uncommon to find

newer pools, constructed according to present standards, which had deteriorated through poor operation and maintenance. The swimming pool classification program was undertaken to eliminate the substandard pools by rehabilitation or closure.

Procedures

Trained sanitarians from local health departments, serving 50 of the 55 counties in West Virginia, are responsible for providing the following on pools in their areas:

1. Outdoor pools: Each week while the pool is in operation, one bacteriological sample is taken; and free and combined chlorine residual, pH, and water clarity readings are recorded on a bacteriological survey sheet.

2. Indoor pools: Reporting is the same as for outdoor pools except inspections are made monthly and two bacteriological samples, one from the deep end of the pool and one from the shallow end, are provided.

All bacteriological samples are taken at a time when the pool has a substantial bather load and at the point or points of poorest chlorine distribution and the points of highest bather load, or both. The clarity standard is a 6-inch black disk on a white background, placed at the deepest point in the pool and observed from 10 yards. If the disk is clearly seen, water clarity is classified as "good," if dimly seen, "fair," and if not seen, "poor."

This information is submitted immediately to the State health department, where it is recorded. It is then returned to the sanitarians

Mr. Jacobson is assistant engineer of the division of sanitary engineering, West Virginia Department of Health, Charleston. He presented this paper at the twenty-first annual meeting of the Southern Branch of the American Public Health Association, Baltimore, Md., April 17, 1952.

Figure 1. Distribution of swimming pools according to classification and type, 1950-52.

along with the results of the bacteriological samples.

An engineer from the State health department's division of sanitary engineering visits each pool at least once a year—outdoor pools during the month of June and indoor pools prior to January 1. He inspects the pool, with the help of the local sanitarian, and scores it, using the Swimming Pool Classification Schedule. This schedule provides for scoring of pool construction, dressing room conditions, water treatment facilities, bacteriological count, and operation practices. It lists maximum points, indicating satisfactory attainment, for each item and subitem. The scores determine classification of the pools as AA, A, B, or C.

This classification program is patterned after a program developed by R. G. McCall of the

University of North Carolina. The standards used are based on the report on "Swimming Pools and Other Bathing Places," published jointly by the American Public Health Association and the Conference of State Sanitary Engineers. Minimum construction and operation requirements include the following:

1. Pool construction: Required to be of impervious, smooth material; overflow gutters around periphery of pool with drains at 15-foot intervals; sufficient inlets and outlets to produce uniform circulation, maintain chlorine residuals, and eliminate dead spots; depth proportions sufficient to provide adequate area under 5 feet and adequate depth at diving end; fence or barrier around pool area; ladders for exit from pool; and proper depth markings.

2. Dressing rooms: Located conveniently to

pool with entrances at shallow end and access to pool only after passing through a shower; one shower per 40 bathers expected at time of maximum load; and one toilet per 40 women and one toilet plus one urinal per 60 men.

3. Water treatment: Turnover, with filters, every 8 hours or less; constant head orifice or positive displacement pump-type chemical feeders for alum and soda ash; positive feed chlorinator and control kit; indicator to show rate of filtration and backwash; wash water visibility; hair and lint catchers; suction cleaner; loss of head gauges; and absence of cross connections with city water supply.

4. Operation: Chlorine residual at least 0.3 ppm free available chlorine or 0.8 ppm combined chlorine; pH between 7.0 and 7.6; water clarity as indicated above; no sediment or slime on pool bottom; inspection of bathers prior to entering the pool for cleanliness, respiratory infections, open cuts or sores; and adequate lifeguards and first aid equipment.

The active participation of the local sanitarian in this program is an essential requirement for its success. Out of a possible total of 100 points, about half (47) are based on information submitted by him.

Thus far pool grades are available only to the pool owner and the local health department. It is intended, however, that, when the program becomes a State health department regulation, grades shall be announced publicly—on July 1 for outdoor pools and on January 1 for indoor

Figure 2. Relationship between bacteriological quality of pool water and chlorine residuals.

Figure 3. Distribution of samples according to chlorine residuals.

pools. A continuous record will be kept on each pool from the information submitted by the local sanitarian, and when this information indicates a change of classification, the change will be made and publicly announced. It is also planned that operating permits will not be issued to pools classified as C. At present, public opinion is the chief "wedge" for improvement, although the State health department can and does close dangerous public pools.

Prior to the outdoor swimming pool season of 1951, four 1-day swimming pool clinics were held at various locations in the State. These clinics were well attended, and it was generally agreed that they were of help to pool operators and owners. Included among topics discussed were: modern recirculation equipment; good swimming pool housekeeping; chemical treatment and control; swimming pool paint and resurfacing material; and the pool classification program.

Results

A great deal of improvement has been made in practically all swimming pools in the State, and the interest and cooperation of the pool owners and operators have been very good.

Figure 1 illustrates graphically the improvement made in outdoor pools. During the 2-year period (not including 1952), 48 percent of the fill and draw pools have been converted to the recirculation type. The number of Class AA and Class A pools has increased 39 percent, and the number of Class C pools has decreased 29 percent.

It has long been established that free chlorine is a much better disinfecting agent than combined chlorine. A comparison of the effects of these two agents on the bacteriological quality of pool water substantiated this point (fig. 2). The data for this analysis were based on 819 samples of pool water (4,095 10-ml. portions) and 819 chlorine residual readings, submitted by the local sanitarians.

In interpreting figure 2, consideration should be given to the data in figure 3, which show that a comparatively small number of samples was submitted for high combined-chlorine residual readings. This portion of the curve in figure 2, therefore, is not as accurate as the rest. However, it should be pointed out that since no pools in West Virginia use chlorine-ammonia treatment, samples containing combined chlorine at concentrations of 0.5 and above probably contained some free chlorine. Furthermore, although uniform instructions were issued to all sanitarians on the methods by which free and combined chlorine should be determined, it is reasonable to assume that these instructions were misinterpreted by a few.

Summary and Conclusions

After 2 years of experience in operating a swimming pool classification program on a trial basis, the West Virginia State Department of Health reports the following results and conclusions:

1. The interest and cooperation of the local sanitarian are necessary to the success of the program.
2. Free chlorine has been verified as a better disinfecting agent than combined chlorine.
3. The number of fill and draw pools has been reduced 48 percent.
4. The number of Class AA and Class A pools has been increased 39 percent.
5. The number of Class C pools has decreased 29 percent.
6. The interest and cooperation of pool owners and operators have been very good.
7. The results obtained indicate that the program is worth while, and it is planned to continue it within the limits of existing facilities.

Onchocerciasis: The Blinding Filariasis

16 mm., sound, color, 17 minutes. 1951.
Audience: Physicians, medical students,
specialists in tropical medicine.

Available: Loan—Apply Public Inquiries
Branch, Public Health Service, Federal
Security Agency, Washington
25, D. C. Purchase—To be ar-
ranged through Castle Film Division,
United World Films, 1445 Park Ave-
nue, New York 29, N. Y.

Serving both as a graphic intro-
duction to onchocerciasis and as an
interesting documentation of an

epidemiological approach to the
study of this important tropical dis-
ease, this film was produced jointly
by the Laboratory of Tropical Dis-
eases, National Institutes of Health
and the Pan American Sanitary
Bureau.

It is divided into five main sec-
tions: etiology, epidemiology, clini-
cal manifestations, diagnosis, and
treatment.

The etiology section details the
clinical and laboratory investigative
techniques used, including biopsy
sampling, microscopic and pho-
tomicrographic observation, and
microgross examination of the Sim-
uliidae. The epidemiology section
documents the fly habits, larvae,
pupae and adult stages, and collec-
tion-identification methods by dye

powder coloring. The section on
clinical manifestations elaborates
on the chronic aspects of the disease
and discusses, by means of the
perimeter and corneal microscope,
the conditions of photophobia, con-
junctival pigmentation, atrophy of
the iris, and visual acuity. The
diagnosis section includes biopsy and
microscopic examination, particu-
larly the characteristic protein reac-
tion induced by oil of hetrazan.
Surgical methods and methods of
medication involving suramin so-
dium compounds, such as ger-
manin, bayer 205, and antrypol, are
portrayed in the treatment section.

The majority of the footage of the
film was taken by Dr. Thomas A.
Burch, in the Yepocapa area of
Guatemala.

Environmental Health Needs

In a Dynamic Society

By MARK D. HOLLIS, C.E.

When we speak of a healthful environment, we think mainly of safe, wholesome, palatable water, of a healthful diet, of clean air, and of shelter for our families where they live, and work, and rest.

The need for a healthful environment is common to all peoples: it cuts across boundaries of occupation, race, class, and politics. If it differs from neighborhood to neighborhood, and from region to region, it differs not in fundamentals but only in complexity.

Today, our Nation's needs for environmental health services are the most complex in history because of the environmental changes created by economic and technological advances. The job today for environmental services is to keep up with, or ahead of, total historical trends.

If we do not keep ahead of some of these changes, we may be obligated to suffer them indefinitely. Already we are dangerously behind the trend in water pollution. In communities like Los Angeles, will people continue to suffer from polluted air?

Are we committed to live with a scandalous number of home and highway casualties?

Are we endangering future generations by our increasing exposure to ionizing radiations?

We have come a long way since Benjamin Rush attacked filth in Philadelphia. A century ago, we were obliged to advance the techniques of sanitation by a trial and error process.

Assistant Surgeon General Mark D. Hollis is the chief sanitary engineering officer of the Public Health Service.

Shortly thereafter scientific studies began the identification of microbes, leading to the modern life-saving techniques of pasteurization and chlorination. Since then, also, teams of health workers have organized effective attacks upon a host of disease vectors. Equally significant studies prepared the ground for the chemical approach to nutrition.

Today, the Nation aims to carry on what has been begun so well. Also, we are beginning to explore relatively new worlds: the viruses, fungi, and pollens; the effects of noise, radiations, dusts, temperature, humidity, and other physical forces; the environmental needs of an aging population; nutritional and other environmental factors in chronic disease; methods for reducing the appalling toll of home accidents; and the biological effects of penetration of the environment by commercial chemicals.

The feed-back process creates new problems as rapidly as old ones are solved. The chemicals used to control vectors, for example, may themselves become environmental hazards. Radiations used to sterilize sealed foods, an imminent development, may themselves be hazards in the working environment.

The outstanding historical trend is the increasing rapidity and continuing complexity of environmental change. Though we may realize that industrial production has increased sevenfold since 1900, it is difficult to sense the significance of the fact that half of this increase has come within the past 10 years. The speed of progressive technology has tossed us far out onto uncharted waters. From here on, we travel without precedent. We must review our

health programs constantly and adjust them frequently to keep in pace with the times.

Our Resources

Our 300-billion-dollar productive capacity assures the ability to provide essential environmental services. We have the material resources, the knowledge, and the techniques with which to train personnel. We have also a respectable body of capital equipment for water and sewerage systems, for food processing, for shelter of all kinds, and for laboratory experiments. Public water supply systems serve more than half the population, and they serve 90 percent of the families in the areas where they are installed. About 90 percent of fluid milk on the market is pasteurized. Even though specific deficiencies remain, we have unquestionably the greatest per capita investment in the world in a healthful environment.

Our institutional resources are equally valuable. With the collaboration of private institutions, we have formed the core of a successful team of Federal, State, and local public health agencies. The present pattern of administering public health programs assures flexibility and opportunity to experiment and to diversify. At the same time, it makes possible the development and use of uniform standards, equipment, or methods, once the advantages of uniformity are fully realized.

Health departments, to be sure, have not engaged directly in every field of environmental health service: often services are managed as commercial or mechanical functions and sometimes with little regard for their relationship to public health.

Current Needs

Our paramount need is to recognize that a healthful environment is a basic social objective. Such recognition should be established not only among professionals but also among the general public. It is not merely a matter of securing funds to support health work. Funds now available are not always spent as well as they should be—where there is no appreciation of prime health objectives.

Where health is a major objective, money can be used to anticipate future health problems. It is not necessary to delay action until there is a

clear and present danger. Professional health workers usually know the need for environmental services years before public opinion and public officials support such services.

Widespread recognition of health objectives may also help to extend participation in health activities to persons outside the public health profession. Environmental health services have grown so complex that they can no longer be managed exclusively by a handful of public health employees—a mere 8,500 engaged in sanitation work in all State and city health departments. Active collaboration must come from physicians, engineers, farmers, food handlers, builders, and city planners, to name but a few of the professions and trades concerned.

Traditionally, health work has been negative: it has aimed to prevent disease rather than to promote health.

We are in a position today to conceive of health in positive terms. We can define healthful living conditions, and we can work toward such conditions.

For example, it would have been good engineering and good economics, too, if we had worked as hard to secure and protect clean raw water as we have worked to treat polluted water. The positive concept applies to housing, dental health, and to other fields. The positive concept of health may be the decisive difference between environmental health work as we have known it and as we may see it in the future.

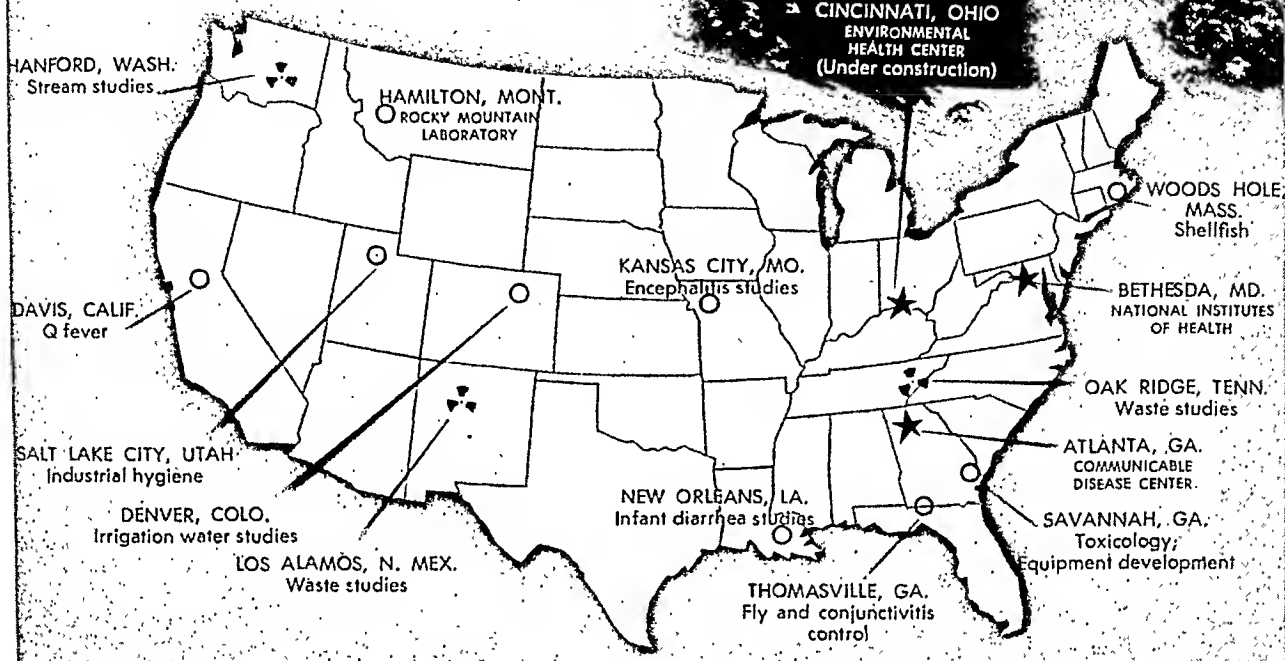

As we consider specific fields for positive action—air, water, food, and shelter—it would seem we have two simultaneous tasks. One is to increase progress in established fields. The other is to probe the unknown, to probe new problems, and to develop new instruments and new tactics.

In recent years, there has been a tendency for environmental services to remain static. This tendency results partly from the hypnotic effects of routine, partly from the failure to value these public health services as highly as personal health services, especially for certain chronic diseases, and partly from indifference to obsolescence of practices and equipment.

Air

Although, pound for pound, our intake of air is 10 times as much as our intake of water, the

LOCATIONS OF CURRENT ENVIRONMENTAL HEALTH LABORATORY RESEARCH ACTIVITIES U. S. PUBLIC HEALTH SERVICE

—From "Environment and Health," Public Health Service Publication No. 84, 1951.

atmosphere is one of the relatively neglected fields of public health. Presumably, different atmospheric standards would apply to the kitchen, laundry, and nursery; to the school and the factory; to the city and the country. But we don't know what they should be. Meanwhile, we have observed the discomfort of 4 million victims of hay fever; the chronic irritation in Los Angeles; the deaths, notably among the aged, in Donora; and specific lung diseases, such as silicosis and lung cancer, in certain industrial areas. We have seen that a polluted atmosphere attacks not only the lungs but also the skin and eyes. Atmospheric chemicals enter the blood stream also and produce secondary organic effects.

In this field, there is a need for more and better standards; legislation and administrative organization; a better knowledge of the contents of the atmosphere, of the techniques of regulating atmospheric conditions, and of the chronic effects of low-level exposure to impurities. What all this will cost, no one can say,

but it is not likely to cost as much as the present losses that result from dust, corrosion, illness, and other effects of atmospheric pollution.

There is need also to strengthen determination to act in the presence of alarming changes in the natural environment before all the evidence is in. This policy is needed to deal with radioactive dusts and with germs or poison gases which may enter the air, whether by accident or design, as well as with the more familiar hazards. We can't afford to postpone corrective action until all scientific questions have been answered.

Water

Although the highest use of water in our society is to relieve thirst, its other uses are equally essential. For this reason, we have come to feel it has been a basic error to separate the need for a safe drinking water supply from the need to prevent gross pollution of the raw water source. The tendency today is to approach the development and utilization of

the water resource as a unit. Water is a factor in nutrition, dental health, waste disposal, shelter, atmospheric conditioning, radiation exposure, recreation, and in industrial production.

The need to maintain and extend basic water services is unrelenting. We should extend the public supply lines to the 10 percent of the population living in settled areas which are not now served. Seven million homes need to be supplied with running water. Water-carriage systems of waste disposal are needed in an even greater number of homes. Four million rural families need new or improved water sources.

There is need also to reclaim water in polluted sources; to abate pollution now entering streams, lakes, and harbors; to extend the practice of fluoridation; and to improve techniques for managing certain trade wastes. There is a need also to modernize techniques.

There is need to anticipate expanding demands and uses of water. The economy may be expected to grow at a rate of 3 percent a year. It is predicted that, by 1975, output will be double the level of production in 1950. The Census Bureau estimates a population of 193 million in 1975, with a working force of 82 million. The work week is expected to be 15 percent shorter. And labor productivity is expected to rise 2.5 percent annually. These figures all suggest increases in both the total and per capita level of consumption of goods and services.

The backlog of proposed water works construction projects is estimated at \$1.4 billion. The backlog of sewerage projects proposed is put at \$2.4 billion. This backlog does not contain all projects needed to anticipate future needs arising from the growth of population and production. A 10-year program of investment in treatment facilities for municipal and industrial wastes is estimated to run from \$9 to \$12 billion.

Food

Unless there is danger of infection or poisoning, it is usual to think of food as a commodity. Environmental services have applied to the food environment rather than to the food itself. But with the development of a positive view towards health, the tendency is to think of food less as a commodity and more as an essential to

health. This tendency was accelerated by the experience of England during the war years. There the general level of nutrition was improved despite a decline in the total quantity of food available. American concern with the quality and quantity of diet and its availability began with isolation of the vitamins and with Goldberger's pellagra studies. The extent of malnutrition 20 years ago intensified this concern.

Economic developments since 1941 seem to have turned the tables: for Americans, the major food problem today seems to be obesity. Deficiency diseases—pellagra, beriberi, and rickets—have become relatively rare. But we still lack a sound index of where we stand on nutrition. The practice of adding vitamins to certain foods is a voluntary act by the processor.

Efforts to protect food from contamination have been aimed chiefly at certain organisms and their toxins. The need to apply such protection to public eating places is chronic. But we have little of the knowledge needed to control chemicals in food. The select committee of the House of Representatives to investigate the use of chemicals in food products (H. R. Res. 323, 81st Cong.) states there are 704 chemicals used in food, and only 428 are known to be safe. Some chemical additives, in appropriate amounts, are beneficial, as are fluorides, iodine, or vitamin D. But others may bear further investigation. A Federal food board has been suggested to rule on the safety of using chemical additives.

The need for uniform regulations, uniformly administered, has been noted particularly in the food industry. Fortunately, the milk industry and public authorities have developed a co-operative program which seems likely to facilitate the movement of milk across State lines. Uniformity is expected also to achieve major economies in the design, manufacture, and use of equipment.

Shelter

Our concept of shelter was once limited to a roof and four walls, but this concept has broadened to the belief that environmental services focus upon the health of the family in the home, and that the safeguards applied at the

water works, the factory, the school, the office, or the dairy are simply extensions of the family roof.

In practice, decent shelter provides a potable supply of water, sanitary disposal of sewage and garbage, healthful atmosphere and temperature, and good lighting; quiet and privacy; enough space for safe movement; for storage, and for play; screening and other protection against pests or disease carriers; safe, fireproof design and construction; and reasonable access to community facilities in an orderly neighborhood. These are rough specifications of what is meant by the national housing policy approved by Congress, stating that "the health of the people . . . requires a decent home and a suitable living environment . . . for each American family"—(Public Law 171, 81st Cong., 1st sess.).

Despite this policy, and despite a prodigious record of building in the past 5 years, one-third of the Nation's dwellings today have one or more basic health defects. As noted above, 7 million dwellings lack running water. Only half of these are in farm areas. Another 7 million lack hot running water. Almost 7 million dwellings are overcrowded. Almost 13 million dwellings lack decent toilet facilities, and only a third of these are in farm areas. More than 12 million have no shower or bathtub, and less than half of these are on farms.

Before the discovery of microbes, health departments actively enforced minimum standards of health and sanitation in housing, because they recognized that these were their best defenses against disease. A short-sighted notion that germs could be controlled without sanitation tended to discourage this activity. Another reaction against sanitation occurred as a result of the use of DDT and other chemicals. A few enthusiasts began to think that disease-carriers could be controlled chemically without sanitation measures. They have since learned that they were wrong.

The current housing shortage has encouraged progressive health departments to apply enforcement measures to improve the supply of decent shelter. Baltimore, Los Angeles, and Milwaukee are among more than 40 cities with programs under way. Health departments in at least 40 other cities have initiated programs.

Such programs could add 500,000 decent units a year to the present supply for over 30 years.

Builders and real estate operators are giving this movement their support. Public health officials, recognizing that private building and public housing cannot satisfy the total demand in all income brackets for decent homes, can contribute outstandingly to this one phase of the shelter problem. There is a need to apply the standards of decent shelter also to the facilities used by a million migrant workers and by other transients.

Personnel and Training

A review of personnel and training must consider that environmental services are not the private domain of a single profession exclusively. The health team has replaced the individual professional in health practice. But even in the team, we look to the individual leader. Leadership is given to the personality with the capacity and competence. It is not a professional monopoly.

The need for broad-gauge men and cooperative relations with those in related fields is indicated by our industrial growth. Our economic future depends upon the determination of industrial engineers and health workers to keep the byproducts of modern technology under control.

The emerging problem of ionizing radiations appears to be one mainly of organizing competence in local and State health departments. Their responsibilities in the atomic age are suggested by the growth of the facilities of the Atomic Energy Commission and the concomitant use of radiations in private industry. Health departments will soon require the knowledge and training to protect this generation, and future generations, from the consequences of excessive exposure. Meanwhile, there is a great need to establish programs to evaluate radiation exposure and to develop protective practices.

Research

To overemphasize the importance of broad, popular understanding of the environmental conditions fundamental to public health would be difficult. Perhaps the development of a broad understanding should be a phase of ad-

ministrative research. The key to this need may be that the man at the desk seldom takes the total health needs as seriously as he takes the water supply in his own kitchen. It is difficult to stir him with the fact that accidents in the home are the leading cause of death in children. Chronically, he takes the view that home accidents happen to somebody else, until they happen to him. There is a need to know how such a personal view of public health can be broadened.

Other research needs—the need for modern techniques of operation and management, and the need for modern procedures for evaluating health conditions and techniques—have been mentioned previously in relation to specific operations.

However, one relatively untouched but important field of research is the study of the relationship between health and total economic prosperity. On the one hand, we need to know what health services the economy can afford. On the other, we need to know how much environmental controls contribute to the expansion of the economy. It would be useful to know on what terms our resources could assure a decent home for every family. It would be useful also to measure the effects of health on the productivity of the working population or the cash advantage realized from industrial uses of water. Both industry and the public may benefit from such studies. With such knowledge, we may find it possible to raise health standards substantially.

For water pollution control particularly, there is a need for continuous, automatic monitoring instruments, such as we have developed for measuring radiations. New kinds of measuring instruments are needed too, because the character of pollution has changed in recent years. The development of these instruments obliges us to inquire whether the expense and complexity of the operation is justified, but generally any machine may be used in repetitive operations to advantage. There is a need to develop techniques for removal of specific pathogens from water and for removal of organic chemicals and radioactive substances. There is need for a major shift in emphasis from the simple disposal of waste material to its capture and conversion into useful commercial prod-

ucts. This need is the more urgent in view of the depletion of certain nonrenewable resources and the importance of organic fertilizers. This need will grow with time.

If it is agreed that environmental research seeks practical applications rather than basic knowledge, then it is important to evaluate both research and operations in terms of the ends we seek. Such evaluations would determine whether our efforts are meeting their objectives. They would provide a solid basis for planning. And they would tell us whether we are developing techniques and facilities to deal with predictable developments.

Summary

Environmental health services today need greater recognition to enable the Nation to adjust to the demands of a rapidly changing environment. Recognition may come if the public learns to associate personal needs in environmental services with the public need. Recognition may be improved also by open efforts to advance and extend familiar services, and to develop future services.

The four fundamentals of environment—air, water, food, and shelter—in the United States right now present a complex assembly of inter-related needs. In each field there are the recurrent needs of administration, personnel, research, and positive concepts.

To look ahead, it appears a certainty that our hopes and objectives for public health are bound to be integrated with public policy as a whole, our economic development, our role in world affairs, our social institutions, and our common hopes and aspirations.

The pessimists among us are convinced that society is about to enter a new eclipse of ignorance and darkness. The optimists are confident that the golden age is around the corner. One must be a realist; one must recognize the complexities and difficulties of this period of transition and still endeavor that, with no problems completely resolved, we shall use our technical powers so that the next generation will still have grounds to feel confidence and pride in its health services. We have reason to hope that, within the next 20 years, the Nation need not suffer neglect of the environment of any family, any neighborhood, or any community.

A Coordinated Investigation of a Food Poisoning Outbreak

By FERDINAND A. KORFF, MATTHEW TABACK, A.M.,
and J. HOWARD BEARD, M.D., M.P.H.

The investigation of an outbreak of food poisoning near Baltimore in July 1951 demonstrates a statistical epidemiological procedure which, it is believed, will be of value in determining offending foods in the absence of laboratory analyses. The purpose of this type of investigation is to locate the focus of poisoning so that measures which will decrease the possibility of recurrence of the unfavorable incident may be applied.

Initial Report

On July 19, 1951, the bureau of food control, Baltimore City Health Department, learned from a friend of one of the victims that a number of office workers had become ill after attending a picnic the previous day. The picnic was sponsored by the employees of a local insurance company. The office manager of the company was therefore requested to complete the questionnaire used by the Baltimore City Health Department in investigating outbreaks of food poisoning. The following information was obtained.

On July 18, 1951, the office personnel of the insurance company held an "outing" at a semi-

private resort approximately 30 miles from the city in an adjoining county of the State. Traveling by private automobile and public bus, 320 employees plus friends reached the resort at about 1 p. m. The day was cloudy, humid, and warm. Upon arrival, a number participated in bathing, horseshoe pitching, golfing, and playing soft ball. Exercise was normal, not too strenuous for such an occasion. Beer and pretzels were served constantly, "as much as desired." At about 6 p. m. a buffet style meal was served in an open casino. The food, displayed on tables and served by temporarily employed food handlers, was sliced cooked ham, recently fried crab cakes, potato salad, sliced tomatoes, heated baked beans, sliced bread, ice cream, cake, and hot coffee. Single-service containers only were used. Illness, principally nausea and vomiting, began about 2 hours after the food was eaten.

Field Investigation

On July 20, 1951, the county health officer investigated the resort food-handling procedure and interviewed the manager of the resort. It became readily apparent that the remainder of the food had been disposed of and that the manager was on guard so that the outbreak would not affect his future income from the resort. However, it was ascertained that the precooked ham, potatoes, and beans were purchased from a jobber nearby and delivered to the resort on the morning of the picnic. The crab meat in cans was stored in a standard

Mr. Korff is director of the bureau of food control and Mr. Taback is director of the bureau of biostatistics, Baltimore City Health Department, Baltimore, Md. Dr. Beard is assistant health officer of the Anne Arundel County Health Department, Annapolis, Md.

family-sized electric refrigerator until the time of preparation. The tomatoes were procured the afternoon of the picnic from a wholesale vegetable supplier.

The management supplemented the regular staff of four cooks and waiters with nine extra helpers for the day. Food preparation began at 2 p. m. and was continued until serving at 6 p. m. The precooked ham, tomatoes, cake, and ice cream did not demand any special preparation.

The potato salad preparation began at 2 p. m. and continued until 4 p. m. This salad consisted of cut potatoes, saladaise, onions, peppers, pimento, celery seed, pickled relish, vinegar, salt, and pepper. The saladaise was procured in 1-gallon jars, which were kept in a basement storeroom until used. In the preparation of the salad a single gallon jar of saladaise had been used. The pickled relish was also purchased in 1-gallon jars which were kept in a basement storeroom until used. All other ingredients were either fresh or kept on hand as standard season products in the usual commercial containers. The cook used his hands to mix the salad ingredients. There is every reason to believe that he did not wash his hands before

preparing the salad, although neither the manager nor the cook would confirm this statement. After preparation, the salad was covered with waxed paper and left on the work table until serving time.

The crab meat in cans was delivered to the kitchen at noon of July 18, and the cook immediately began to prepare the crab cake patties, which consisted of bread crumbs, Worcestershire and Tabasco sauce, parsley, and pimentos, in addition to the crab meat. The patties were placed on large fryers and fried in deep fat at approximately 350° F. Before heating, the patties and ingredients were handled by the cook. The crab cakes were ready for serving about 5 p. m.

At approximately 5:30 p. m. the crab cakes, potato salad, baked beans, coffee, sliced ham, sliced tomatoes, sliced bread, squares of cake, ice cream in dry ice containers, paper napkins, individual cups, spoons, forks, and plates were transported in an open truck from the kitchen to the picnic area. The food was placed on long tables and served by the waiters to the line of guests, beginning at 6 p. m. Some of the party continued to have "seconds" until about 10 p. m., at which time the service was discontinued. After the remaining food was removed from the picnic area to the kitchen, it was given to the extra helpers to eat and to take home. The manager stated that not a single case of illness developed among the persons who consumed the food "leftovers." This statement had to be accepted as true.

The inspection of the kitchen revealed that general sanitation was "fair." The most sig-

nificant findings were: (a) improper cleaning of the meat grinder, resulting in residual putrified meat on the parts; (b) 70° F. temperature in one of the two family-size iceboxes; (c) cracked work-table top; (d) no three-compartment sink for cleaning and disinfecting equipment; (e) glasses standing on shelves; (f) no facilities for handling kitchen working utensils; (g) no easily available hand-washing facilities. The general condition of work tables and butcher tables indicated the need for better equipment.

The water used was procured by electric pumps from a 90-foot driven well. For the last few years it has been of acceptable quality. A bacteriological analysis of the water taken on June 11, 1951, was negative for coliform organisms.

From the questionnaire information, 146 persons stated that they had become ill. The total number of persons fed, according to the manager of the resort, was 332.

Statistical Analysis of Food Histories

Questionnaires initiated by the bureau of food control and completed by persons attending the picnic provided information on 304 individuals. To facilitate analysis, punch cards were prepared for each person providing a food history.

The statistical analysis of the data obtained through the questionnaire was designed to indicate which segments of the group attending the picnic were selected for attack by gastrointestinal disease.

A description of the individuals attending the picnic, according to age and sex, is shown in table 1. The attack rate among females was significantly higher than that for males,

Table 4. Attack rates for specified food combinations

although the difference, approximately 10 percent, was not striking. Differences are noted among the age groups, but here also it is apparent that the attack of all groups at a high rate is of more significance than the differentials.

A distribution of the individuals who were attacked, according to time between eating the food and onset of symptoms, is shown in table 2. The median time of onset was 5.2 hours, with 85 percent of all cases occurring from 3 to 8 hours following consumption of food. The outbreak of gastrointestinal disease appeared therefore to be associated with a single focus of exposure.

The manner in which individuals in attendance were attacked, according to their food histories, is given in table 3. The highest attack rate occurred among persons eating potato salad. However, relatively high rates also occurred for each of the other foods. The baked beans, tomatoes, and ice cream, however, could be considered as not being the cause of the illnesses. The beans were recently cooked and served hot; the ice cream was pasteurized under supervision and consumed by many persons who did not attend the picnic; and the tomatoes, unless contaminated by a chemical, could not be the cause of the illnesses. The severity as well as the timing of the illness did not indicate that it was caused by a contaminating chemical. The search for the offending

Table 3. Attack rates according to food consumed

Food consumed	Total eating	Number ill	Number not ill	Percent ill
Ham.....	230	108	122	47
Crab cake.....	235	124	111	53
Potato salad.....	246	142	104	58
Tomatoes.....	253	127	126	50
Ice cream.....	201	98	103	49
Beans.....	258	129	129	50

food was therefore narrowed down to the ham, crab cakes, or potato salad.

In view of the fact that the individuals attending the picnic had eaten several foods, it was thought that high rates of all suspect foods were the result of their close association with one another so far as their consumption was concerned. In order to determine the specific effect of a single food, a series of attack rates for combinations was undertaken (table 4). In the absence of potato salad, the attack rates associated with crab cake and ham became relatively insignificant. The attack rate for potato salad, however, remained high whether or not the salad was associated with other foods. Thus, high attack rates were associated specifically with the consumption of potato salad.

This method of determining attack rates for various food combinations is not too often possible because the number of individuals from whom detailed data can be secured in conjunction with a food poisoning incident is usually small. An alternative procedure commonly employed is the comparison of attack rates for persons consuming particular foods with attack rates for persons not consuming the specified foods. This type of analysis is shown in table 5.

Statistically significant differences in attack rates are obtained only for potato salad and crab cake. In the remaining cases, the attack rates seem to be independent of the consumption of the given foodstuffs. This type of analysis, although usually capable of providing a clear-cut inference concerning a source of food infection, only narrows down the possibilities in this incident. The information in table 4 furnishes the final solution to the specific vehicle of infection.

Table 6. Distribution of ill persons according to time of onset and symptoms of disease

Total	120	26	146
1			
2	3		3
3	11	2	13
4	31	4	35
5	30	2	32
6	23	4	27
7	13		13
8	2	2	4
10	1		1
11	6	12	18

An explanation of the manner in which potato salad could have caused the illnesses may be developed from a study of the distribution of time of onset of symptoms, shown in table 6, and from the information obtained by the health officer during his investigation.

The only food of the three suspected ones that was handled with the bare hands and eaten without subsequent heat treatment was the potato salad. The deep-fat frying procedure used in the preparation of the crab cakes requires the fat to be above 300° F., which is sufficient to destroy any thermo-stable staphylococcic enterotoxin that may have been present. Ham usually becomes infected only in spots. The salad, with less solid consistency, maintained at a temperature of about 70° F. and prepared about 4 hours prior to serving, provided ample opportunity for infection, growth of the organism, and formation of the enterotoxin. The time of onset of the illness, 3 to 8 hours after consumption of the food, and the symptoms, chiefly emesis, indicate poisoning by an entero-

Table 5. Attack rates for specified foods according to history of consumption

Type of foodstuff	Total eating	Incidence of illness		Total not eating	Incidence of illness	
		Number	Percent		Number	Percent
Ham	230	108	47	74	38	51
Crab cake	235	124	53	69	22	32
Potato salad	246	142	58	58	4	7
Tomatoes	253	127	50	51	19	37
Ice cream	201	98	49	103	48	47
Beans	258	129	50	46	17	37

toxin produced by a staphylococcus. This time of onset and emesis are not indicative of botulism, salmonellosis, or parasitic infection, and poisoning by an inorganic chemical usually causes emesis within a shorter period.

Summary

Although statistical classification is used in this study as the primary instrument for uncovering causal sequences, a certain amount of past experience is also used. It is known that certain foods are unlikely to be responsible for outbreaks in which the symptoms and times of onset of the illness appear to have been caused

by a staphylococcal enterotoxin. Ice cream made by a plant known to pasteurize its product adequately, tomatoes, bread, cake, and coffee are very unlikely to support the growth of the staphylococcus in quantities sufficient to cause the symptoms experienced by those who became ill. The symptoms of the illnesses also probably eliminate a chemical as the cause. Concentration of search, therefore, was pointed to the ham, crab cakes, and potato salad. By determination of attack rates, which are specific for given foods and combinations of foods, a single focus, potato salad, was isolated as the probable cause of illness.

Radioactive Cortisone To Be Manufactured

Radioactive cortisone, which should prove valuable in the study of arthritis and the various metabolic diseases involving adrenal gland hormones, will soon be manufactured in sufficient quantities for research purposes. Funds for this project will be supplied by the National Institute of Arthritis and Metabolic Diseases, Public Health Service.

This cortisone contains radioactive carbon which makes it possible to trace it through the bodies of experimental animals. Such tracer studies may help solve the mystery of how cortisone acts to produce its dramatic effects in health and disease.

A small committee of scientists from non-Federal research institutions will administer the \$66,000 fund allotted for the project. Headed by Dr. Charles Huggins of the University of Chicago, this group will plan the project, bring together the starting materials, and contract with a suitable manufacturer. The product will be distributed to qualified scientists who submit formal research proposals to the National Institute of Arthritis and Metabolic Diseases.

Milk Sanitation Honor Roll for 1950-52

Forty-eight communities have been added to the Public Health Service "honor roll" of safe milk communities, and 42 communities on the previous list have been dropped. This revision covers the period from July 1, 1950, to June 30, 1952, and includes a total of 258 cities and counties.

Communities on the "honor roll" have complied substantially with the various items of sanitation required by the Milk Ordinance and Code—1952 Recommendations, of the Public Health Service. The State milk sanitation authorities concerned must report this compliance to the Public Health Service. The rating of 90 percent or more, which is necessary for inclusion on the list, is computed from the weighted average of the percentages of compliance. Separate lists are compiled for communities in which all market milk is pasteurized and for those in which both raw and pasteurized milk is sold.

The Public Health Service Milk Ordinance, which forms the basis for the milk ratings, is now in effect through voluntary adoption in 397 counties and 1,542 municipalities. These represent increases of 10 and 7, respectively, in the past 6 months. The ordinance has been adopted as regulation by 34 States and 2 Territories. In 11 States and the 2 Territories it is in effect state-wide.

Although the ratings do not represent a complete measure of safety, they do indicate how closely a community's milk supply conforms to the standards for grade A milk as stated in the Public Health Service milk ordinance. High-grade pasteurized milk is safer than high-grade raw milk because of the added protection of pasteurization. The second list, therefore, shows the percentage of pasteurized milk in a community.

This compilation is from the Division of Sanitation of the Bureau of State Services, Public Health Service. The previous listing was published in Public Health Reports, March 1952, pp. 268-271. The rating method was described in Public Health Reports 53: 1386 (1938). Reprint No. 1970.

Although semiannual publication of the list is intended to encourage communities operating under the Public Health Service ordinance to attain and maintain a high level of enforcement of its provisions, no comparison is intended with communities operating under other milk ordinances. Some communities might be deserving of inclusion, but they cannot be listed because no arrangements have been made for determination of their ratings by the State milk sanitation authority concerned. In other cases, the ratings which were submitted have lapsed because they were over 2 years old. Still other communities, some of which may have high-grade milk supplies, have indicated no desire for rating or inclusion.

The rules for inclusion of a community on the "honor roll" are:

1. All ratings must be determined by the State milk sanitation authority in accordance with the Public Health Service rating method, which is based upon the grade A pasteurized milk and the grade A raw milk requirements of the Public Health Service milk ordinance. (A recent departure from the method described consists of computing the pasteurized milk rating by weighting the pasteurization plant rating twice that of the raw milk intended for pasteurization.)

2. No community will be included in the list unless both its pasteurized

milk and its raw milk ratings are 90 percent or more. Communities in which only raw milk is sold will be included if the raw milk rating is 90 percent or more.

3. The rating used will be the latest submitted to the Public Health Service, but no rating will be used which is more than 2 years old. (In order to promote continuous rigid enforcement rather than occasional "clean-up campaigns," it is suggested that when the rating of a community on the list falls below 90 percent no resurvey be made for at least 6 months. This will result in the removal of the community from the subsequent semiannual list.)

4. No community will be included on the list whose milk supply is not under an established program of official routine inspection and laboratory control provided by itself, the county, a milk control district, or the State. (In the absence of such an official program there can be no assurance that only milk from sources rating 90 percent or more will be used continuously.)

5. The Public Health Service will make occasional check surveys of cities for which ratings of 90 percent or more have been reported by the State. (If the check rating is less than 90 percent, but not less than 85, the city will be removed from the 90-percent list after 6 months unless a resurvey, submitted by the State during this probationary interim shows a rating of 90 percent or more. If the check rating is less than 85 percent, the city will be removed from the list immediately. If the check rating is 90 percent or more, the city will be retained on the list for 2 years from the date of the check survey, unless a subsequent rating during this period warrants its removal.)

Communities Awarded Milk Sanitation Ratings of 90 Percent or More, July 1950-June 1952

				Kanawha County, 96.....	6- 6-1952

NOTE: In these communities the pasteurized market milk shows a 90-percent or more compliance with the grade A pasteurized milk requirements and the raw market milk shows a 90-percent or more compli-

ance with the grade A raw milk requirements of the Public Health Service Milk Ordinance and Code.

Note particularly the percentage of milk pasteurized in the various communities listed. This percentage

is an important factor to consider in estimating the safety of a city's milk supply. All milk should be pasteurized or boiled, either commercially or at home, before it is consumed.

Professional Examinations For Public Health Service Officers

By SIDNEY H. NEWMAN, Ph.D.

Professional examinations play a significant role in the professional lives of the individuals who take them. Traditionally, they have been of the essay or discussion type. Only recently has the objective type of examination been used in professional examinations. But more and more, objective professional examinations for a variety of purposes are being developed by Federal and State civil service systems, by professional specialty or diplomate boards, by professional licensing boards, and by professional or graduate schools (1-7). The Public Health Service is in the fore of this trend.

The problems of examining candidates for appointment as commissioned officers in the Public Health Service are relevant to all professional examinations. To be considered are the factors of fairness and accuracy, adequacy of construction, and measurement of professional competence and significant intellectual processes.

Officer Selection

Membership in the commissioned officer corps of the Public Health Service offers a lifetime career to the successful candidate. The Public Health Service offers two types of commissions: Regular and Reserve. Officer grades and salaries correspond to their equivalents in the Army and Navy.

Dr. Newman, a psychologist, is chief of the research branch, Division of Commissioned Officers of the Public Health Service.

The officer selection and evaluation program of the Public Health Service, initiated in the fall of 1947, is among the first to attack, in a broad and systematic manner, the problems of selection and evaluation of medical, scientific, and other professional health personnel. The development of efficient, objective methods for selecting the best qualified officers and for assuring equitable personnel actions within the commissioned corps is the goal of the program.

Professional examinations constitute only a part of the selection and evaluation procedures of the program. Background, personality, interest, and aptitudes are all recognized as factors important to the success of a Public Health Service officer. Selection methods also include interview board and file-evaluation board procedures as well as medical examinations (8).

Why Professional Examinations?

Professional examinations are designed to measure professional competence and knowledge. The individual undergoing examination is expected to demonstrate his ability to understand and to utilize the principles and knowledge of his profession. In solving examination problems, moreover, he will use the intellectual processes of reasoning, judgment, organization of ideas, integration of specific facts into generalizations, and application of facts and principles.

There is ample evidence that examinations are measuring individual differences among applicants for the commissioned officer corps. The evidence lies in the widely distributed scores

in the 150 or more different objective professional examinations which have been administered since 1947.

It is apparent that the possession of like professional degrees does not guarantee the exhibition of similar professional abilities, as measured by the tests. Professional competence is a clear-cut requisite for satisfactory performance in the commissioned officer corps. Therefore, it is important to identify all candidates who stand relatively low on the scoring.

Objective Examinations

The objective type of test is most commonly utilized because of its generally accepted advantages over the discussion or essay kind:

More accurate and more equitable comparisons among candidates are possible because the rapid machine-scoring of the tests is uniform, and bias is eliminated.

By yielding more reliable and more stable results, the test scores are better suited to statistical treatment, making it possible to develop test standards and to compare groups of candidates.

The candidate is required to deal with the subject of the question, thereby revealing his strength or weakness.

It is possible to examine a candidate's professional competence and knowledge more quickly, more intensively, and more extensively.

The five-alternative multiple-choice form is the kind of objective question now used. The question states a problem or situation and presents five answers or solutions, only one of which is considered to be correct. The question is not limited to verbal material—it may contain diagrams, pictures, graphs, symbols, or numbers.

Although it is planned to explore the possibilities of other objective test forms, three main considerations led to the current use of the multiple-choice question. First of all, it lends itself to reliable, uniform, and stable scoring. It can be carefully constructed to measure complex intellectual processes. Also, it has been found easier to demonstrate to subject-matter experts the construction of complex multiple-

choice items than the construction of various other forms of items.

Questions which assess rote memory and straight knowledge are used as little as possible.

From four to six 3-hour objective examinations in each professional category are used in selecting officer candidates for the Regular Corps. Objective examinations are also used, partly, for promotions within the Regular Corps to the grades of assistant and senior assistant, which are the equivalents in the Navy, for example, of lieutenant, j. g., and lieutenant. A brief but comprehensive 3-hour test is administered to Reserve Corps applicants in designated categories. Each examination usually contains from 100 to 150 items.

Practical and Essay-Type Examinations

Two other types of professional examinations are used in the selection and evaluation program. These are the 10-hour practical work examination for dental officer candidates and a specially devised essay examination for scientist officer candidates.

In the practical dental examination, the candidate places an amalgam restoration in a patient's mouth and constructs a gold inlay in a green or ivory tooth. The candidate is observed while performing the restoration at an examining center by two dental officers who independently rate his work on specially constructed observation-rating schedules. The gold inlays are sent to a central board of three dental officers in Washington who independently grade the cavity preparation and the finished inlays on special rating scales. The third part of the examination is completely objective: the candidate responds to multiple-choice questions by identifying oral pathological conditions which have been depicted on color slides.

Various studies of the observation and rating methods used in the practical dental examination are in progress. The administration and scoring of the practical examination have proved to be satisfactory. It is likely that practical work tests in some other professional categories would also be useful.

In the scientist officer examination, the discussion-type questions on scientific problems

and research are planned to measure characteristics of originality, judgment, and organization and expression of ideas. Even though this kind of question does have disadvantages, it is worth while to see if the essay question, when carefully constructed by scientist officers, could aid in the measurement of complex intellectual processes.

Rating scales similar to those generally used for evaluating individual performance have been developed for improving the grading of the essay question. Degrees of performance are defined for the graders, and score points are assigned to each question. Three scientist officers independently grade each paper.

The specially devised essay examination for scientist officers will afford an opportunity to study the reliability of this type of approach as well as the relationship between scores obtained by essay and objective methods.

Examination Construction

The Professional Examination Service staff of the American Public Health Association collaborates with the research branch personnel of the Division of Commissioned Officers of the Public Health Service in constructing objective examinations. In this cooperative endeavor, each organization performs the functions it is best equipped to do. The determination of examination policy, structure, and content is the responsibility of the research branch and other Public Health Service officers. The APHA Professional Examination Service staff aids and advises in the planning.

Procedural steps in constructing professional examinations are outlined:

1. Specialists in the professional fields prepare outlines covering the subject matter relevant to the training and experience requirements for each profession.
2. Experts in the subject profession prepare examination items on specified topics. They are given instructions for constructing multiple-choice questions and descriptions of the intellectual processes which the items should measure.
3. Test construction specialists check the items for format, grammar, and intelligibility.
4. A specialist in the subject field reviews the

items for accuracy, content, and adherence to construction outline.

5. Experts in the appropriate professional field review logically grouped items.

6. Specialists revise the items in the light of criticisms from the expert reviewers.

7. Experts select the best of the reviewed items and arrange them in the examination according to subject matter and estimated difficulty.

After administration of each examination, continuous analyses of test scores and test items are used to improve and revise the examinations.

Test-construction procedures give reasonable assurance of the soundness, accuracy, and appropriateness of each item. Up to the present, approximately 1,900 experts in various professional fields have participated in the construction of tests. About 80 percent of these experts are not in the Public Health Service. A minimum of five experts reviews each test item.

Regular Corps Examinations

Professional examinations have been developed for selection of Regular Corps officers in each of the 10 major professional categories of the commissioned officer corps. Within professional categories, entrance and promotion examinations are given for the grades of junior assistant, assistant, and senior assistant. Professional examinations for different grades may bear the same title but may vary in content or in scoring standards.

The scope and variety of professional examinations which have been prepared for the Regular Corps since 1947 are seen in the list.

New examinations for physical therapist, sanitarian (medical social worker), sanitarian (psychiatric social worker), and scientist (physicist) are in preparation, to be given for the first time in 1952-53.

Effectiveness

Underlying the use of the professional examination is the theory that measurable differences in professional competence will be related to professional competence exhibited later in the Public Health Service. Testing this theory is

Regular Corps Examinations

DENTAL OFFICER

Oral: Bacteriology, pathology, medicine, and surgery.
General: Anatomy, pathology, and pharmacology.
Operative and prosthetic dentistry, and dental materials.
Periodontia, roentgenology, pedodontia, and dental public health.
Practical work-performance.

DIETETICS OFFICER

Junior Assistant and Assistant

Institutional management.

difficult, primarily because of the necessity for finding a reliable measure or criterion of professional competence as demonstrated on the job. A first approach to this problem has been made.

Criteria of Success

As a research project, Public Health Service officers at many installations rated each other on 20-point rating scales. These strictly confidential ratings of job proficiency, administrative ability, personality, and value to the Public Health Service were made with the understanding that the results would not be used in any type of personnel action. The ratings became the criteria for developing a new efficiency

report and for validating methods of selecting officers. The new efficiency report should be a useful criterion of job performance.

However, such criteria as group ratings and efficiency reports are not actual, direct measures of work performance. Some aspects of job proficiency may be reflected in the group ratings, but other proficiency factors may be omitted.

For example, the practical work examination for dental officer candidates could more directly measure competence in clinical dentistry than could group ratings. This is not to disparage the importance of such ratings as useful criteria, particularly where colleagues might

readily observe factors of job competence during daily contacts.

It is hoped that future research will develop reliable and direct measures of actual work performance in the various professional categories. They could serve as validation criteria for professional examinations, group ratings, and efficiency reports.

Intellectual Measurements

Corollary to the theory that professional examinations do measure professional competence is the hypothesis that they also are measuring such complex intellectual processes as interpreting, judging, reasoning, and integrating. To test the hypothesis, it is appropriate to ask, "What intellectual processes are most closely related to successful performance in the Public Health Service?"

Since multiple-choice items are constructed to measure complex intellectual processes, and are accepted by testing experts as doing so, they furnish a good starting point in seeking answers to the above question. Suitable analytical studies of the relationships between the items might reveal interrelated groups of items, and might yield hypotheses or data on the factors measured by each group. The relationship of each group to criteria of performance in the Public Health Service could then be studied. Those item groups yielding scores most closely related to performance could serve as models for similar items or questions. In addition,

forms of objective test items other than multiple-choice questions could be similarly investigated.

More Research Needed

Because there is surprisingly little published research about professional examinations, the experience of the officer selection and evaluation program and of the APHA Professional Examination Service will benefit organizations that use, or plan to use, professional examinations. It is evident that careful planning and research are needed to develop professional tests which are adequate, suitable, and appropriate to the measurement that is required and which actually measure professional competence and knowledge with the utmost scientific objectivity.

ACKNOWLEDGMENTS

Appreciation is expressed for the aid and support of the following officers in the initiation and development of the officer selection and evaluation program: Deputy Surgeon General W. Palmer Dearing, formerly chief, Division of Commissioned Officers (1947-48); Medical Director Eugene A. Gillis, formerly chief, Division of Commissioned Officers (1948-52); Medical Di-

rector Robert H. Felix, director, National Institute of Mental Health.

Shaw Heads Division of Hospitals

The appointment of Dr. James R. Shaw as chief of the Division of Hospitals, Bureau of Medical Services, Public Health Service, was announced in July.

Formerly medical officer in charge of the Public Health Service Hospital, Detroit, Mich., Dr. Shaw succeeds Dr. G. Halsey Hunt, who was recently named associate chief, Bureau of Medical Services.

In 1936, after receiving his medical degree at the University of Michigan Medical School, Dr. Shaw joined the Public Health Service as medical intern, assigned to its hospital at New Orleans, La. In addition to a fellowship in internal medicine at the Mayo Clinic, Dr. Shaw took postgraduate work in hospital administration at Stanford University, San Francisco, and the University of California. Before coming to the Public Health Service Hospital in Detroit, Dr. Shaw's Public Health Service career included assignment in the internal medicine departments of several of its hospitals and out-patient clinics, a tour of duty as district Coast Guard medical officer, Long Beach, Calif., and medical officer in charge of the Public Health Service clinics at Los Angeles and San Pedro, Calif.

VDRL, Kahn, and Kolmer Tests for Syphilis

By SIDNEY OLANSKY, M.D., AD HARRIS, FRED G. HARB, M.D.,
HILFRED N. BOSSAK, B.S., and ROXIE NEVIL, B.S.

The diagnosis of central nervous system (CNS) syphilis is frequently dependent on laboratory findings. The spinal fluid tests most widely employed include white cell counts, total protein determinations, colloidal precipitation techniques, and complement fixation or flocculation tests for syphilis.

Several studies comparing the VDRL and Kolmer spinal fluid tests have been reported (1-3), but the laboratory findings were not correlated or compared with physical findings or diagnoses.

In a 6-month cooperative study by the Venereal Disease Research Laboratory of the Division of Venereal Disease, Public Health Service, and the Alto Medical Center of the Georgia State Department of Health, on 5,539 patients admitted to the treatment center, the VDRL, Kahn, and Kolmer tests on the spinal fluid of each patient were evaluated in their relation to other laboratory findings and diagnoses.

Methods

Duplicate tubes of spinal fluid were collected from patients admitted to the treatment center at Alto. A white cell count, total protein determination (biuret method), and Kahn test

were performed on one tube of this fluid in the laboratory at the treatment center. The second tube of spinal fluid was sent to the Venereal Disease Research Laboratory at Chamblee, Ga., by auto (approximately 60 miles and 2 hours away), where the VDRL and Kolmer tests for syphilis and another total protein determination (4) were performed.

For analyses, the results of the VDRL, Kahn, and Kolmer tests are divided into reactive (positive and doubtful) and nonreactive (negative) groupings. The broad relationship of the results of these three tests in this study is shown in table 1.

Disagreement existed between results obtained with VDRL, Kahn, and Kolmer tests on 132 spinal fluids. Agreement-disagreement ratios for these tests for syphilis, on this group of specimens, and correlation of these results with other laboratory findings and diagnoses are recorded in table 2. White cell counts of five or more and total protein of 41 mg. per 100 cc. or greater were considered as abnormal findings for the categories in table 2.

When they were admitted to the treatment center, all patients in this study had evidence of syphilis infection, including a positive or doubtful blood test. Since the doctors at the treatment center received only the results of the Kahn and other tests performed in the laboratory at that facility, positive reactions in the VDRL and Kolmer tests were not used as bases for diagnoses of asymptomatic neurosyphilis. However, positive Kahn tests on spinal fluids were frequently the prime, and sometimes the only, determinants of decisions regarding asymptomatic neuroinvasion phases of syphilitic infection.

Dr. Olansky is director of the Venereal Disease Research Laboratory, Venereal Disease Division, Public Health Service, Chamblee, Ga.; Mr. Harris, assistant director, is chief of the serology section, and Mr. Bossak is assistant chief. Dr. Harb and Miss Nevil are medical officer in charge and laboratory director, respectively, of the Alto Medical Center, Alto, Ga.

Patients in categories C and D, "No neurosyphilis diagnosis" (table 2), are those who have had no such diagnoses on previous admissions, or during the present admission to the Alto rapid treatment center. However, discharge diagnoses from present admissions may in some instances be altered in this regard if attending physicians consider that cell count and total protein spinal fluid findings indicate neuroinvasion.

Analysis of Test Results

The figures recorded in table 1 show little percentage-wise differences between the three listed tests. However, 12 more positive reactions were reported for the VDRL test than for either the Kahn or Kolmer method. Since admissions to the treatment center at Alto are principally predicated on positive blood tests for syphilis without reference to current spinal fluid findings, and, since spinal fluids used in this study were collected from unselected routine admissions over a period of 6 months, the reactivity rates recorded in table 1 probably represent average expectancy in the selected population group served by this center. Of the 5,539 spinal fluids tested in this study, 9.1 percent (an average of 1 to each 11 admissions to the treatment center) reacted in one or more of the three spinal fluid tests for syphilis.

Results of the Kahn and Kolmer tests (table 1) appear to be in closer agreement than are those of the VDRL test with either of the other two tests. However, reference to the test agreement-disagreement listings in table 2 shows that there is greater agreement between the VDRL and Kolmer tests than between any two of the other tests. In the 132 instances where the three tests failed to agree, the VDRL-Kolmer combination was reactive 38 times and nonreactive 52 times—a total agreement of 90 times. In this group of discrepancies, the Kahn-Kolmer combination showed agreement in 30 instances and the VDRL-Kahn combinations agreed only 12 times.

All other findings in tests for syphilis on the 5,539 spinal fluids used in this study were in agreement, that is, all three tests were nonreactive (5,036) or all three tests were reactive (371). The VDRL and Kolmer tests were in

agreement on 5,497 of 5,539 spinal fluids tested (99.2 percent), the Kolmer and Kahn test combination agreed 5,437 times (98.2 percent), and the VDRL and Kahn test results agreed in 5,419 spinal fluids (97.8 percent), tested in this study.

Table 1. Results obtained with VDRL, Kahn, and Kolmer tests of spinal fluids of 5,539 patients

Tests	Number of spinal fluids			
	Reactive (positive and doubtful)		Nonreactive (negative)	
	Num- ber	Per- cent	Num- ber	Per- cent
VDRL-----	437	7.9	5,102	92.1
Kahn-----	425	7.7	5,114	92.3
Kolmer-----	423	7.6	5,116	92.4
1 or more tests-----	503	9.1	-----	-----
All 3 tests-----	371	6.7	5,036	90.9

In categories A and B, made up of patients with a diagnosis of neurosyphilis, as in categories C and D, which were made up of patients in whom this diagnosis was lacking, approximately equal numbers of positive reactions (table 2) were obtained by using the VDRL test alone, the Kolmer test alone, and both the VDRL and the Kolmer test. A large proportion (44 of 52) of the reactions (+) in the Kahn test alone were in the group of patients having neurosyphilis diagnoses. However, these two types of findings were definitely influenced by the fact that many original diagnoses of neurosyphilis were predicated on Kahn spinal fluid test findings alone, since results of the other two tests for syphilis were not available to the attending physicians at the time that the original diagnoses were made. It was also interesting to note (table 2) that in only two instances were reactions in both the Kahn and Kolmer tests accompanied by negative findings in the VDRL test. Although reactions with either the VDRL or Kahn test were associated with negative Kolmer test findings, a negative Kolmer test was found in no instance where both the VDRL and Kahn tests reacted (+).

In patient category A (table 2) 18, 15, and 13 positive or doubtful reactions (+) were ob-

tained with the Kahn, VDRL, and Kolmer tests, respectively. In the B category of this table, 28 Kahn, 18 VDRL, and 14 Kolmer test reactions (+) were reported. Since 19 of the 48 diagnoses in the B category were made on Kahn test findings alone, these figures, and, conversely, those in the C and D categories were weighted in favor of the Kahn test by this factor.

The C category of table 2 shows 13 VDRL, 9 Kolmer, and only 3 Kahn test reactions (+), while the D category contains 20 VDRL, 16 Kolmer, and only 5 Kahn test reactions (+). The significance of the diagnosis on the basis of the Kahn test alone in categories B, C, and D in influencing these findings is stated in the preceding paragraph.

A comparison of the results of the VDRL, Kahn, and Kolmer test findings with abnormalities in the cell count and total protein reports may be visualized by combining findings recorded in categories A and C (table 2). The 53 spinal fluids in these two categories had higher than normal findings in either or both protein content and cell count. In these 53 spinal fluids, positive (+) findings were obtained in 28, 22, and 21 instances by the VDRL, Kolmer, and Kahn tests, respectively. Thus, a slightly greater correlation was obtained between positive findings with the VDRL test and cell count plus total protein results than was

produced by either of the other two tests for syphilis.

The test in use in the laboratory providing the data on which the original diagnosis is based is in a favored position. Since asymptomatic neurosyphilis is a laboratory diagnosis, the result of the test for syphilis often establishes the diagnosis. For example, in the B category, (column 2, table 2), 19 patients were diagnosed asymptomatic CNS syphilis on the basis of a positive Kahn test alone. Had the VDRL or the Kolmer spinal fluid test been used instead, there would have been no diagnosis of CNS syphilis in these instances. In other words, since the diagnosis is based on laboratory findings, the particular test employed in the institution will check 100 percent with the diagnoses. In the category of asymptomatic CNS syphilis, it is impossible to determine the specificity of the spinal fluid tests for syphilis, since the clinical findings are normal. One may be partially guided by the cell count and total protein, but abnormalities in these, although frequently more significant, may be even less specific than the spinal fluid tests for syphilis.

Our findings can point out no marked superiority of any of the test procedures studied. However, since the diagnosis of CNS syphilis may be determined by spinal fluid tests for syphilis, which may disagree, more information is available to the diagnostician if two or more

Table 2. Relationship of 132 discrepant reactions obtained with the VDRL, Kahn, and Kolmer tests on spinal fluids to clinical status of patients

Categories ¹	VDRL+ Kahn— Kolmer—	VDRL— Kahn+ Kolmer—	VDRL— Kahn— Kolmer+	VDRL+ Kahn+ Kolmer—	VDRL+ Kahn— Kolmer+	VDRL— Kahn+ Kolmer+	Total
A. Neurosyphilis (past or present), cell count ² and/or total protein ³ abnormal.	5	18	3	0	10	0	36
B. Neurosyphilis (past or present), cell count and total protein normal.	8	26	2	0	10	2	48
C. No neurosyphilis, cell count ² and/or total protein ³ abnormal.	5	3	1	0	8	0	17
D. No neurosyphilis, cell count and total protein normal.	10	5	6	0	10	0	31
Total.....	28	52	12	0	38	2	132

¹ By diagnosis and present cell count and/or total protein.

² Abnormal cell count=more than 5 per mm.

³ Abnormal total protein=more than 40 mg. per cubic centimeter.

⁴ Includes 19 diagnosed as having asymptomatic CNS syphilis with the Kahn test the only positive spinal fluid finding.

+ Positive or doubtful.

— Negative.

Directory of State and Territorial Health Authorities, 1952

Revised as of May 1, 1952, the directory lists all State and Territorial health authorities and the officials of the State agencies participating in grant programs administered by the Public Health Service. Health officials of each State are presented on the basis of the State's organizational pattern for carrying out the health activities incorporated in the comprehensive health program. The State agencies, other than health departments, listed are: mental health agencies, hospital planning and construction agencies, and water pollution control agencies. Public Health Service personnel in charge of functions closely associated with State health departments are also listed.

for the general public

Snake Bite

The first part of this leaflet is devoted to information on the habits of snakes, where they rest, and when and how they attack. The reader is given advice on ways of protecting himself from possible snake bite. This is followed by detailed instructions for first aid treatment with emphasis on keeping the victim quiet. Getting the patient to a physician or hospital for antivenin as quickly as possible is stressed. The reader is also instructed on how to administer first aid if alone when bitten.

• • •

Snake Bite. Health Information Series, No. 10 (Public Health Service

Publication No. 188). Revised 1952. 2-fold leaflet. 5 cents; \$1.25 per 100.

Heart Disease

Because of advances in knowledge of heart disease and an increased demand for information on the Nation's leading cause of death and disability, the National Heart Institute and the Division of Chronic Disease and Tuberculosis, Public Health Service, have brought up to date and expanded three earlier leaflets to form a new series of four.

Heart Disease. The first in the series contains general information on the physiology of the heart, the current status of knowledge on heart disease and a brief discussion of the three common types, rheumatic heart disease, coronary artery disease, and hypertension, in terms of cause, manner in which they affect the heart, and the age groups involved. The reader is advised that symptoms of heart disease may or may not be apparent and the warning signs may indicate that something else is wrong. A physical check-up once a year is suggested and emphasis is placed on cooperation of the patient with his physician in the treatment of heart disease.

Rheumatic Heart Disease. This leaflet contains a discussion of the cause of rheumatic heart disease, rheumatic fever, the streptococcal infection that usually precedes it, and the ways in which the heart itself may be damaged by the infection. The difficulty of diagnosis is pointed out, with a description of the various tests the physician will use in detecting the disease. The importance of the role of the parents in caring for a child during prolonged bed rest is stressed. Means of preventing recurrent attacks of streptococcal infection are suggested and the need for community health facilities is discussed.

Coronary Artery Disease. Presented as the story of Roger Franklin's heart attack, this leaflet gives information on the coronary arteries, how they function, and how coronary artery disease affects them. The manner in which nature develops collateral circulation following

coronary thrombosis is described, emphasizing the necessity for maintaining a balance between rest and activity, and the necessity for cooperation between the patient and his physician during treatment.

Hypertension. The fourth leaflet in the series begins with a description of the mechanics of high blood pressure, or hypertension—the tightening up of the arterioles, and the loss of the elasticity of the blood vessels. While it is explained that the reason for these changes is unknown, some probable causes are suggested. Variations in normal blood pressure and low blood pressure are discussed as in the first three leaflets, and following the doctor's advice in the course of treatment is stressed. A list of common-sense rules for the hypertensive patient are given at the end, the most general one being moderation in everything.

Single copies of most Public Health Service publications can be obtained without charge from the Public Inquiries Branch, Public Health Service, Washington 25, D. C.

Perspectives

in the Practice of Public Health

DURING the past half century the concepts and the practice of public health have undergone an evolutionary development of increasing momentum and significance. In the wake of the great sanitary awakening and the golden age of bacteriology came the control of communicable disease and the management of the primary threats to infant and maternal survival. Latterly there has come more adequate medical care, a closer linkage of curative and preventive medicine, and the beginnings of serious attacks on the chronic diseases through organized research and community action. There has been increasing recognition of the broader implications of the terms "environmental health" and "occupational health," of the health implications of a maturing United States population, and of the impact on health of a shrinking world. Yet these are but a few of the components which must be dealt with today when we speak of "the public health."

An enlightened perspective is demanded if we are to meet successfully the day's tasks and are to prepare intelligently for coming challenges. *Public Health Reports*, in common with other scientific journals, deals largely with current history, with records of contemporary research, with evaluations of the present and relatively immediate past, and with an occasional probing into tomorrow.

Together with the *American Journal of Public Health*, our pages mirror many segments of the history of public health since 1878; through these pages one can follow, if he will, the growth of a great biosocial movement. But broader obligations than mere reporting rest upon a journal such as ours. It is also our task to provide continuing opportunities for critical appraisal of policies and practices and for review of the record.

This issue of *Public Health Reports* marks a serious effort to meet our obligation afresh. Regrettably, the occasion is the passing of a distinguished figure from the public health scene—Dr. Joseph Walter Mountin. His career is reviewed in the following pages by his friend and colleague, Dr. Thomas Parran, who has chosen to look upon this chronicle with a degree of historical perspective. The fact is Dr. Mountin's career spanned an era of public health, and his record is inextricably interwoven with the story of public health from the 1920's to the present. Particularly it is a significant portion of the story of the Public Health Service, for in a profound manner the man's work and his organization interacted upon one another.

We are, of course, too close to the facts to measure Dr. Mountin's contribution to public health. He was one of a company of dynamic personalities who, in actuality, changed the very life of America. Time will reveal the scope and depth of his particular influence, his vision, his basic practicality. However, it is worth reviewing now, in the spirit of Dr. Mountin, the events of these past three decades. For we are in a period of great change, moving toward a momentous synthesis of medicine and public health; and much of what we may expect is pointed to in the career of public service and in the writings of this man.

Over the years *Public Health Reports* has been privileged to publish many papers by Dr. Mountin and his co-workers. The posthumous publication in this issue of the last two papers he presented, together with Dr. Parran's article, adds to a significant chapter in the history of a vital and purposeful social movement.

THE EDITORS

A Career in Public Health

By THOMAS PARRAN, M.D.

In late 1895 a diphtheria epidemic was raging through eastern Wisconsin. Two of the seven children on the Mountin farm in Hartford were stricken. It was a small town. Medical facilities were meager; the new diphtheria antitoxin in short supply. Doctors did what they could, but the deaths continued to climb. In the Mountin household, Ned, age 5, succumbed. His younger brother, Joe, managed to pull through.

During his lifetime, Joe Mountin was to see diphtheria and many other infections virtually conquered. But he was to be no mere spectator on the sidelines as the United States advanced from an epidemic-ravaged, insanitary country to one which is among the nations having the highest standards of health and productivity. He was to be an indefatigable leader, giving his entire adult life to the service of others, in the great biosocial movement that is public health. Almost every phase of that movement felt the impact of his mind and energy.

Man and Organization

Mountin came to the Public Health Service soon after graduation from medical school, had the experiences common to a medical career in public health, advanced in position and responsibility through the years, and became chief of

one of the important bureaus of the Public Health Service shortly before his death. At first glance, this could be the biography of any one of a number of first-rate administrative officials in public health or other fields, in Federal or State government, who merit remembrance for a job well done.

There was something more to Joe Mountin. He was a cut above most of his contemporaries—above and ahead—yet he was of them and part of a working partnership with his colleagues.

When Joseph W. Mountin died at 61, April 26, 1952, the American people lost a devoted public servant, the public health profession lost one of its most stimulating philosophers, and the world health movement lost a pioneer.

He was all of these largely because of two things: Mountin had vision—a vision of the future, but with first steps in the present. Equally significant, he was part of a functional, purposeful organism which was itself responsive to stimuli from within as well as from without.

The Public Health Service encompassed his entire professional career. It was a compatible union not unmarked by superficial differences and periods of minor discord, but based on a mutual respect that grew stronger year by year. Much of what he was and did was possible largely because he was a working element of a many-faceted but integrated organization as it grew into a place of increasing significance in the total health arena. He, in turn, had much to do with the growth and development of the Service.

Dr. Parran, dean of the Graduate School of Public Health of the University of Pittsburgh, was Surgeon General of the United States Public Health Service from 1936 to 1948.

The Surgeon General's staff in 1942. Left to right: Assistant Surgeons General Joseph W. Mountin, States Relations Division, R. E. Dyer, National Institute of Health, Lawrence Kolb, Division of Mental Hygiene; Assistant to the Surgeon General Warren F. Draper; Surgeon General Thomas Parran; Chief Inspection Officer L. R. Thompson; Assistant Surgeons General M. C. Guthrie, Division of Foreign and Insular Quarantine and Immigration, Paul M. Stewart, Division of Personnel and Accounts, E. R. Coffey, Division of Sanitary Reports and Statistics, W. F. Ossenfort, Division of Marine Hospitals and Relief. Not present, Assistant Surgeon General Raymond A. Vonderlehr, Division of Venereal Diseases.

Public Health Beginnings

Mountin's reputation does not rest on any single outstanding accomplishment. His name is not associated with any great medical or research achievement, nor with the discovery of a new cure for disease, nor even with the administration of a particular health program that had immediate, dramatic results. His contributions were varied, all-embracing, identified with a wide spectrum of public health. The measure of his stature may be found in this very diffusion, in the catholicity of his interests and influence. For he viewed public health in terms of all the resources which could be brought to bear upon the objective of more satisfying and more healthful human life. Years ago he foresaw the synthesis of medicine and public health as a positive concept and practical possibility.

In 1891, when Mountin was born, public

health was in the golden age of bacteriology, but health conditions were poor. Epidemics of cholera and yellow fever were constant threats. Malaria was endemic over large areas of the country. Filthy and insanitary conditions characterized most of our cities. As a result typhoid fever was rampant and infant mortality high. Services for the prevention and care of communicable diseases were fragmentary, and what health machinery existed was meager.

These conditions changed but slowly during Mountin's boyhood and youth. Perhaps they fired his youthful imagination with curiosity and his humanitarian instincts with determination. In any event, he chose a medical career, and after receiving a medical degree in 1914 (with a bachelor of science in 1916) served internships at the Milwaukee County and the Chicago Lying-In Hospitals. His natural curiosity about hospital and dispensary or-

ganization was stimulated in these years, and he made a special tour to study clinical organization and management in several eastern cities. Upon his return to Milwaukee he organized the Marquette University Dispensary Clinic, which he directed for about a year.

Mountin began his public health career in 1917 with his friend and classmate, John F. Mahoney, who 29 years later was to receive the Lasker Award for developing penicillin treatment for syphilis. Each joined the Public Health Service as a "scientific assistant."

World War I had brought to the Public Health Service an important new responsibility—safeguarding the health of military personnel and civilians in areas around Army camps and in new defense communities. State health organizations were still incomplete. The local health unit movement was just getting under way. Health machinery in the States and communities was almost totally inadequate to meet the increased demands suddenly imposed by the war. It was necessary to turn to the Federal health agency for organizational and technical assistance in adopting preventive measures and in erecting emergency sanitary safeguards.

Mountin's first assignments for the Service were in extracantonment health work in Louisville, Des Moines, and Waco. He was commissioned in the Regular Corps as an assistant surgeon in July 1918, and early the next year entered upon the sequence of training assignments common to most young Public Health Service officers of his day. This gave him experience in quarantine duty, in the marine hospital service, and in health administration.

The Missouri and Tennessee Days

I first met Joe Mountin in September 1921 when he reported to me for duty in the Tri-State Sanitary District in Joplin, Mo. I explained to him that our job was to try to persuade some of the county boards of supervisors and local Red Cross chapters to support county health units—each with a full-time health officer, a nurse, a sanitary inspector, and a clerk—and that we also could expect some financial help from the Rockefeller Foundation and from the Metropolitan Life Insurance Company,

which was interested in a nursing service in some of the mining counties where health conditions were bad.

There was a great deal of trachoma in the Ozarks then, and we were told, too, that almost everyone in the fertile cotton growing counties of southeast Missouri had malaria. There was, in short, much to be done. I suggested that Mountin look around the State, become acquainted with the people and their needs, and report back.

Later when Joe was telling me what he had learned in rural Missouri, he observed that local health work was a far cry from quarantine duty with its implicit sense of power and authority. He noted that at his present task first he had to learn, then convince others of an idea. "In quarantine," he said, "we work by the book, but down here there isn't any book, so . . ."

So he had to "write" the book—and in a sense that was what he was doing throughout his career: identifying and describing public health problems, many of which were not even seen by others at the time; devising ways and means of meeting them; and stimulating people to apply and develop tools and methods.

In 1922 we moved to Jefferson City primarily to work more closely with the Missouri State Health Department in promoting local health units. It was the Public Health Service's policy then, as now, on request to aid State and local health departments by the loan of personnel when needs are great and the loan is in the interest of the Nation's health.

Mountin was in the field much of the time. Increasingly he seemed interested in southeast Missouri. As events proved, it was not the area's malaria problems alone that commanded his interest, but also a talented, attractive Red Cross nurse, Genevieve Bazan. She became his wife on June 30, 1923, and was his staunch helpmate for 29 years. But neither beloved wife, nor family, nor friends diverted Mountin from his central interest, his work.

Under the general direction of Dr. L. L. Lumsden he remained in Missouri until 1926 (except for a 6-month tour of duty as a student officer at the Hygienic Laboratory in Washington). He organized county health departments, initiated control programs against trachoma, malaria, and tuberculosis, and pro-

moted State health services in the fields of sanitary engineering, public health nursing, maternal and child hygiene, and vital statistics.

Mountin spent the next 4 years in Tennessee, where he gave able assistance to the State health commissioner, the late Dr. E. L. Bishop, in developing State and local public health practices. During this period, too, he began a number of surveys of public health organization and administration. These surveys, an enterprise with which he continued to be associated throughout his professional career, were models of clarity, insight, and analysis. They marked the beginning of his writing career, a career which was to grow tremendously in output and significance.

Conferee and Scholar

While still on duty in Tennessee, Mountin acted as secretary of the public health section of the 1930 White House Conference on Child Health and Protection. This was a new experience to him, at least on a national scale, but his organizing ability and his skill in preparing a report met the test. His understanding and grasp of a total situation came to be widely respected. From then on he was to be called on to act as chairman, secretary, or organizer of numerous meetings of national and international scope in which health, social welfare, and economic considerations were interacting influences. In each he helped to bridge the gap between "public health" and "social welfare."

To him a conference was an opportunity for uncovering facts, for reconciling opinions and attitudes, for action, for progress. He saw a problem, realized that it had to be met, and mobilized all the resources within his reach to work toward a solution.

These early years in the Public Health Service were significant to Mountin, as they have been to most of the Service's professional corps, in providing a rounded experience before a permanent course was charted. He, of course, did not let his education lag then or later, whatever his assignment. He was both teacher and student to the end of his days. He had no M.P.H. degree, but he was in the fullest sense a master of public health.

Study, Analyze, Evaluate

In 1931 Mountin was brought to Washington to take charge of the new Office of Studies of Public Health Methods in the Division of Scientific Research. As he saw it, the purpose of that office was to elevate, through controlled study and critical appraisal, the practical application of public health knowledge to the status of a science. The following description of the functions of the office puts the issues with a clarity that undoubtedly bears his personal touch (1):

"The facts revealed through investigations in the basic sciences need to be applied under controlled conditions before being incorporated into public health programs. Furthermore, a large part of the content of public health programs has been built on the collected experience and judgment of practical health administrators. Such programs need to be analyzed to determine the effectiveness of procedure as well as the economy of its application.

"The future program of the office also contemplates not only the study of specific measures in disease control and health promotion from the analytical point of view, but the conduct of experimental work to develop and test new methods. Such measures should obviate the necessity of trial and error which results if various procedures are immediately incorporated into public health programs."

This passage contains several key words which reveal Mountin's methods and techniques: "study," "experiment," "analyze," "evaluate." He not only applied these principles to his own work, but, of more importance, he was able also to stimulate others to do so. His influence grew geometrically. The impact of this kind of leadership on public health as we know it today is difficult to measure. One thing is sure: It helped mold our present concepts of the role and the significance of organized health agencies. Many of the practices he championed years ago are now taken for granted.

Community Health Surveys

In this period, he conducted or directed numerous health surveys in States, cities, and

counties, working constantly for better techniques, for more meaningful measuring devices, and for simpler recording and reporting practices.

In some studies he not only analyzed the structure and the recorded performance of the health department itself, but he also went directly to families in the community to determine the actual numbers and kinds of services they received from their health agencies—a new approach quickly adopted by others.

Mountin's reports were always brief, pointed, practical. But he left a surveyed community with more than a written report. He left disciples who were dedicated to doing the job that needed to be done. He might be able to find only a small group, or even a single person, with the interest, the energy, and the social conscience to carry on the work—but he found them, and he sparked their imaginations and their wills.

From 1935 to 1937 Mountin was assigned to the National Health Survey. His responsibility was the phase devoted to hospital facilities. The findings were to have many important consequences, not the least of which was a new look at the distribution of hospitals in this country and their role in the total health structure.

In 1937 the Division of Scientific Research was abolished and all its functions consolidated in the National Institute of Health. In this reorganization, several units concerned with statistical investigations, child hygiene, milk sanitation, and water pollution were brought together in a new Division of Public Health Methods with Mountin as its first chief. Its enlarged emphasis was upon the scientific study of sociological, economic, and educational factors in human health. This was a first attempt to integrate the social sciences with the basic research programs of the Public Health Service.

Federal Grants-in-Aid

In 1939 Mountin became chief of the Division of Domestic Quarantine. This division—later the Division of States Relations, now State Grants—in 1936 had been given responsibility

for administration of Federal grants-in-aid to the States for health services under Title VI of the Social Security Act. Earlier (1930) he had written (2):

“Financial aid from extra-county sources is an integral part of county health department administration. Such subsidy should serve both as a promoting and stabilizing influence and at the same time afford a means whereby extra-county governmental agencies may assist in providing a more uniformly adequate local service by distributing the burden in accordance with the resources of the local units of government.

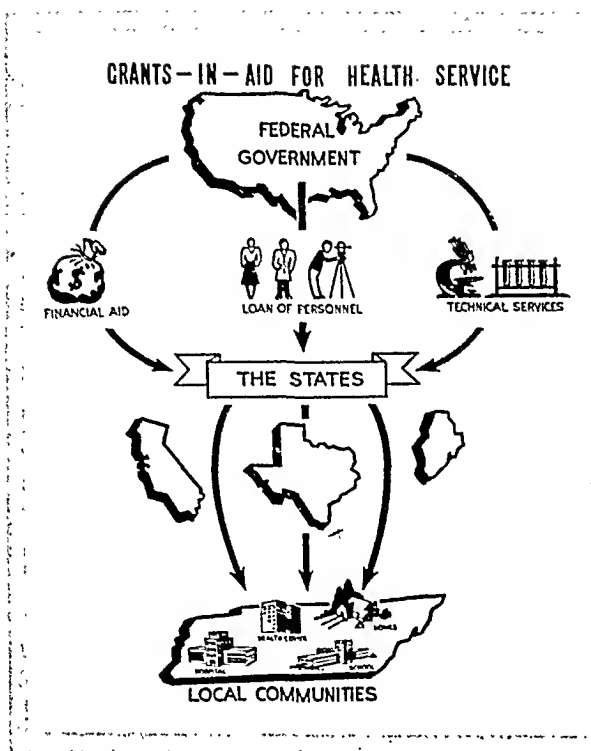

“The subsidy plan should be so designed as to encourage counties to increase their health activities continually rather than to reach some fixed goal and stop there.”

He urged, also, a systemized formula for the allocation of grant funds:

“It is quite important in the projection of a program that local authorities know at the outset what support they may expect over a period of years, barring, of course, unexpected acts of appropriating bodies. If the exact amount of the grant cannot be stated, at least there should be established a fixed rule for apportioning such funds as may become available and for fixing such increases or decreases of subsidy as may be contemplated.”

At his Division of States Relations post, Mountin sponsored modifications and improvements in the planning and administrative aspects of the grants-in-aid system. Perhaps more important, however, was his interest in the development of the technical assistance concept, involving the placing of competent specialists in the district (now regional) offices to provide on-the-spot consultation and technical service to the States.

Mountin believed in State and local responsibility. Frequently he advocated it with such a fervor as to try the patience of many a health officer. As a result, his relationships with the State and Territorial health officers group were sometimes stormy; but always he was pushing for more active, more rational, more farseeing leadership on the part of State and local officials. His last paper—posthumously

One of the "characteristic methods of health administration" as described by Joseph W. Mountin and Evelyn Flook in "Guide to Health Organization in the United States," Public Health Service Miscellaneous Publication No. 35, U. S. Government Printing Office, 1947.

presented before the 1952 American Medical Association meeting—dealt with his decennial surveys of the distribution of health services in State government. It underscored his concern with the growing dispersal of health responsibility among other than health departments.

The War Emergency

At the very outset of Mountin's tour of duty in the Division of States Relations came the national emergency periods and then World War II. Here he was responsible for administering the nation-wide emergency health and sanitation program. This program proved a vital factor in maintaining national health at a high level during the war despite vast disruptions of families, mass movements of population, the mushrooming growth of industrial towns, and shortages of medical, nursing, and sanitation personnel.

The first steps were, as would be expected, fact finding. Even before funds were available, the Public Health Service undertook, at Mountin's urging and under his guidance, what we called "reconnaissance surveys." Survey teams were sent into proposed or newly established military and defense zones. Their findings were on hand when the time for action came and formed the basis for concrete measures designed to protect both the military and civilian communities. The surveys pinpointed specific health problems—a malaria hazard, undue prevalence of venereal disease, an unsatisfactory system of garbage collection and disposal, inadequate mosquito, fly, and rodent control programs. Perhaps more important, they revealed and documented the weak spots in the general public health services.

An important wartime health activity was the program to curb malaria, a potential threat to the health and efficiency of troops and war workers quartered in sections of the country where malaria was endemic. To deal with this problem, the Office of Malaria Control in War Areas was established in Atlanta, Ga., in February 1942.

The problem demanded aggressive, immediate action through direct services to a degree rarely seen in State-Federal health relationships. It was, of course, impossible to separate malaria control in military and war production areas from that of neighboring communities. The MCWA unit, therefore, was an active co-worker with the States, and intensive campaigns to eradicate malaria were carried on throughout the entire endemic area.

Out of this experience—which in 1945 began to include typhus and plague control—Mountin forged another tool of public health administration: the field research and training center. The Communicable Disease Center was created in 1946, built upon MCWA foundations but with a charter that went well beyond the environmental aspects of malaria control. The CDC was to become the Nation's largest center for field and applied research and training in the communicable diseases, and was to act as a reservoir of special competence for service to State health agencies. Mountin is deservedly known as "the father" of this center. In his history of the Public Health Service (3), Dr.

The Communicable Disease Center of the Public Health Service, at Atlanta, Ga., stands as a monument to Dr. Mountin. Here he is shown in July 1948 reviewing architect's plans for the CDC buildings to be located near Emory University. To the left is Dr. R. A. Vonderlehr, then in charge of CDC; to the right is Surgeon General Scheele.

—Atlanta Journal-Constitution photograph.

Ralph C. Williams says: "The Communicable Disease Center owes its beginning to the strong conviction of Dr. Joseph W. Mountin that a need existed in the Public Health Service for decentralizing highly specialized knowledge."

The establishment at Anchorage in 1948 of a field station to be designated in 1950 as the Arctic Health Research Center also was due, almost exclusively, to his efforts. Convinced that we had much to learn about health in the far north, Mountin was one of the first to call for a specific program in arctic hygiene (4):

"The far north is perhaps our last remaining frontier. It contains vast untouched reservoirs of strategic materials and of minerals and vegetation that can enrich the world. These areas are capable of supporting abundant life, perhaps of supporting flourishing civilizations. But human beings have failed to populate them, partly out of ignorance and partly because of the difficulty of adjusting to a new environment. Only to the extent that some of these problems are faced squarely, and only to the extent that hazards to health are explored and eliminated, can Alaska and other parts of the far north attract a stable, home-seeking population.

"In the past, public health activities have developed in the wake of civilization. Now public health is presented with an opportunity to lead civilization, to pioneer in new fields.

By uncovering some of the problems of human life and adjustment in low-temperature areas, public health can become a creative force in opening up new frontiers. At the same time, it can make potentially significant contributions to basic knowledge."

New Training Horizons

War-born shortages of health workers served to reinforce Mountin's earlier insistence on more effective education and continued training. Health programs, he knew, were as successful as the people who conducted and directed them were competent. We need health workers trained not only in the traditional medical fields, he maintained, but in a variety of related disciplines, in practical administration, and in the social sciences. Here is a training plan he evolved and was putting into practice in the spring of 1928 (5):

"The administrative health officer should be trained for his work. This training should cover fundamentals and should afford an opportunity to acquire experience in the practical conduct of the work of a health department. A course of this type will necessitate a close coordination of a teaching institution and an administrative health organization. However, such training facilities are not likely to

be used extensively unless a system is perfected which will provide means whereby training can be made readily available, and unless there be some provision for making training a qualification for employment and advancement. The State health department seems to be the agency best able to sponsor a plan of training; however, the actual teaching should be under the management of an educational institution such as a department of preventive medicine in a medical school or a school of hygiene. The local health agencies should cooperate, particularly for the purpose of making available their facilities for acquiring experience in practical public health administration."

Mountin early recognized the importance of many other professions and disciplines on the health team. He constantly urged, for example, that major administrative responsibility be assumed by people with training and experience in public administration.

Through his early studies of nursing practice, he helped clarify and enrich the role of the public health nurse (6), sharing Welch's concept of them as a "unique contribution of the United States to public health." Many ideas incorporated into the cadet nurse training program of World War II were evolved during the period when public health nursing was a section in the Division of States Relations.

At our staff meetings, in public addresses, and elsewhere Mountin long contended that we were failing to exploit a resource of great potential in neglecting auxiliary workers of all kinds. In one of his last public speeches he said (7):

"Of particular importance is the need for auxiliary and nonprofessional workers. Up to now little serious thought has been given to such personnel as inspectors, aides, technicians, and others who perform many of the routine operations in this country, and who could be relied upon to provide the bulk of services in less highly developed countries. As a result, even when program planning is relatively good, the actual conduct often falls below our expectations.

"This must be considered an important element in sound planning for two reasons. First of all, the training of auxiliary workers should have a high priority in all organizations. Sec-

ond, the organization should be such that maximum use is made of highly trained professional personnel. Routine details should be delegated to auxiliary or less highly specialized workers."

Also, Mountin was instrumental in employing the talents of other professional workers—educators, psychologists, sociologists, economists, medical social workers, social anthropologists—professions outside those traditionally associated with public health.

Commenting on another attribute, Dr. Lewis R. Thompson, Mountin's immediate superior as chief of the Bureau of State Services, remarked in 1941 that "It has been largely through Dr. Mountin that the Service has developed specialists in certain newer fields of public health. In this regard I should like to point out the training of Service officers in the fields of pneumonia, hospital management, public health education, and tuberculosis control."

New Directions

It was characteristic of the man that he was constantly developing new concepts of public health practice. The usual evolution was from the germ of an idea, to a study, to a demonstration or pilot project, and often to a full-fledged public health program. Deliberately he concentrated on planning and promotion, making no attempt to oversee the entire sequence. Often to my dismay he would leave one budding new program for other workers to develop while he pursued new concepts, which sometimes in initial stages seemed almost fanciful. What is important to remember, however, is that such current and substantial activities of the Public Health Service today as tuberculosis control, dental public health, community health education, hospital planning and construction, and chronic disease control had their origins in his division.

Mountin was constantly searching for new techniques and made many contributions to public health methodology. He was a strong advocate of demonstrations and pilot programs, not only as methods of field research, but also as developmental and educational levers for improving State and local health services. The traditional aim of public health to discover and

COORDINATED HOSPITAL SERVICE PLAN

- HOSPITAL
- HEALTH CENTER
- ☆ INSTITUTION (CHRONIC DISEASE)
- △ NURSING HOME (CHRONIC DISEASE)

This diagram represented "some of the preliminary thinking" of the Public Health Service regarding an integrated system of facilities of hospital care and health service. It was first presented by Surgeon General Parran to a Senate committee in 1944, and elaborated upon by Dr. Mountin and his hospital planning group in the following year "as a point of departure" for "those who, now or later, may have administrative responsibilities in this broad area of social interest." It was published in Public Health Bulletin No. 292, Health Service Areas—Requirements for General Hospitals and Health Centers.

develop accurate, simple, and economical techniques for mass application was ever before him. Thus, young scientists of the Public Health Service who had an idea for developing a simplified technique for detecting diabetes or heart abnormalities found a staunch supporter in Dr. Mountin. He, for example, urged the adoption of new case-finding techniques such as small-film radiology in mass chest X-ray programs for tuberculosis control.

Mountin's pioneering on the hospital planning and construction program was typical of his approach. He convinced his colleagues that a research team should be organized to explore the situation. From published data, this team studied hospital distribution and needs on a national basis, county by county, and applied the concept of the "health service area." In this undertaking, our team worked closely with the Commission on Hospital Care set up by the American Hospital Association to pursue a similar objective. The work of the Public Health Service team led to an important

document (8) which outlined a rational pattern of hospital organization (see diagram) within reach of every citizen. In it appears the following passage:

"Under a less complex order than that which is evolving in the United States the traditional detachment of hospitals from social forces might be tolerated, especially if medical sciences also were static. In the presence of social and scientific progress the demand for full utilization of all available resources in the interest of both individual and community health is destined to become irresistible."

Administration and Leadership

The selection of Mountin as associate chief of the Bureau of State Services in 1947 and as chief of the Bureau just 6 months before his death were rather natural results of the interaction of the man and the organization. Here he helped shape policies and programs in widely varying areas of content, from the control of

water and air pollution to vital statistics, and from improving the health of workers to administering the grants-in-aid system.

The notion was understandably prevalent that Mountin lacked the qualities of a practical administrator. He appeared largely indifferent to the mechanics of administration, a cause for complaint among those who supervised him and those whom he directed. Moreover, his administrative techniques often were far from the conventional mold. But if administration is defined as the ability to work with people on a problem and to bring out the

Dr. Mountin (right) representing the Public Health Service in ground-breaking ceremonies for the Clay County Hospital at Flora, Ill., on June 11, 1948, is shown here with Bob Jones, who spearheaded the project. This was the second hospital to be built in the State with the aid of Hospital Planning and Construction (Hill-Burton) Act funds. In his remarks, Dr. Mountin said:

"Today you are breaking more than the ground for a public building. You are breaking through the lethargy and indifference and 'let someone else do it' attitudes that have too long deprived our people of the best in medicine, hospital care, and good health.

"The Clay County Hospital will be the result of this initiative. This is as it should be. The States and local communities can determine their own particular needs better than anyone else. They best can plan to meet them."

best in them, he was an administrator of high order.

An uncompromising intellectual, Mountin attached himself to ideas more than to people. And yet he was able, through the sheer power of his ideas, to stimulate and fuse the interests of whole groups of people in getting a job done. He had the knack of recognizing a good idea when he saw one, of testing its validity, and of putting his own judgment and influence behind the sound idea and the person who conceived it.

Administration is leadership, and Joe Mountin was a real leader. Although he left more unfinished business on my desk than any two score of his contemporaries, we were helped to translate his ideas into action programs by the many restless spirits whom he had inspired. Many Public Health Service officers who themselves have become leaders bear the mark of his thinking and philosophy. He left a heritage of leadership.

Wit and Wisdom

Mountin was a master of the pungent phrase and knew how to use it with devastating effectiveness. His widely renowned wit was both barbed and good-natured, both homespun and urbane. Few who worked with him will ever forget the directness with which he cut through to the heart of a matter. Yet this was infused with warmth, humor, forthrightness, and candor which commanded confidence and respect.

Joe often said that he was "a simple Wisconsin farm boy, born in the shadow of a silo." Consciously he gave this impression, yet in fact he was a sophisticated student of his times. Innate ability was combined with a basic integrity quickly to be recognized.

Part of his strength lay in another of his qualities—the ability to take an abstract or difficult problem and portray it to others in graphic terms. He was able to visualize a problem and to convey a sense of its significance, not only to our own staff but to Congressional committees and to other groups.

Few people were more adept at translating the results of research work into practical public health procedures, but the painstaking routine of laboratory research was not for Mountin. His interest was in critical interpretation, the

This characteristic likeness was caught during the survey and evaluation of the health and sanitation program of the Institute of Inter-American Affairs in the winter of 1951-52. Dr. Mountin is shown here with Dr. John J. Bourke, hospital consultant with the survey group.

drawing of valid generalizations from research results. His was a mind that examined, analyzed, interpreted, and drew things together in form at once deeply philosophical and highly practical.

His written output—his bibliography runs to more than 200 items—was likewise a potent force. His speeches and papers were factual and often inspirational. Several—such as his guide to health services—have become basic documents for students in public health. A large proportion of his work was in collaboration, not only with members of his staff—and he was meticulous in giving credit when due—but with colleagues in other fields and disciplines, inside and outside the Public Health Service.

Foreign Missions

Mountin's advice was often sought for international missions during and after World War II. In 1944 he served as special health adviser to the commission organized by Sir Joseph Bore to plan on the organizational pattern of the Government of India when that country was preparing for its promised freedom. He was the health member of the Social Security Mission sent to Japan in 1947 at the request of General MacArthur. In 1946-47 he and his long-time co-worker, George St.J. Perrott, made an extensive survey of medical and health organization in western Europe. Their reports

are a clear analysis of health insurance plans—including the administration, source and allocation of funds, the quality of service, and the payment for services—in the United Kingdom, France, Sweden, Denmark, the Netherlands, and Belgium.

When the International Bank for Reconstruction and Development organized an Economic Mission to Colombia in 1949, Mountin acted as its adviser on health and welfare. This was the Bank's first attempt to evaluate health, welfare, and education as part of the over-all economic status of a country, giving human resources equal weight along with traditional economic factors in appraising a nation's wealth. Mountin's chapter on health and welfare in the report (9) contains this paragraph:

"Health is probably the most important single component of a standard of living. At the same time it provides one of the most important determinants of that standard. Poor health status means not only failure to reach maximum productivity, but also a drain on wealth and resources. Low levels of health result in many direct and indirect costs, diverting funds and facilities which should be used to strengthen and build the economy. Poor health is expensive in terms of time lost at the farm or the work bench, in terms of the vast needs for more hospitals and facilities of all kinds, in terms of increased costs of welfare insurance, and sickness and accident payments."

Dr. Mountin participated in the first meeting, held in Geneva December 1951, of the World Health Organization's Expert Committee on Public Health Administration. At the committee table are shown four members of the group (left to right): Dr. Ira V. Hiscock, chairman of the department of public health at Yale University; Dr. Mountin; Professor J. M. Mackintosh, director of the department of public health at the London School of Hygiene and Tropical Medicine; and Dr. A. Stampar, professor of public health and social medicine at the University of Zagreb. Other members of the committee were Dr. Karl Evang of Norway, chairman; Dr. Erani Braga, Brazil; Dr. B. C. Das Gupta, India; Dr. Fred W. Jackson, Canada; and Lt. Col. M. Jafar, Pakistan.

At the time of his death Mountin was supervising another important international survey to appraise the 10-year program of health and sanitation of the Institute of Inter-American Affairs.

He also served as a member of the World Health Organization's Expert Committee on Public Health Administration. The first report of that committee, presented to the World Health Assembly in May 1952, contains many of his ideas and ideals (10).

Professional Group Participation

Mountin was as well known for his participation in the councils of many professional and voluntary organizations as for his official work in the Public Health Service. He served, for example, as chairman of the section on preventive and industrial medicine and public health of the American Medical Association, and on

both the governing council and the executive board of the American Public Health Association. He was a "team player" and while it is sometimes difficult to isolate his particular contributions, the influence of his thinking was substantial.

In the APHA, he played an active role as a member of the Committee on Administrative Practice on which he served from 1933 to 1950. He had an important part in developing both the 1940 and 1950 APHA statements on the functions and responsibilities of local health departments. His influence is evident particularly in the latter document (11), with its emphasis on the "ever increasing scope" of local health services.

Mountin also was chairman of the APHA Subcommittee on Medical Care for 5 years. Three important policy statements were developed or produced by the subcommittee during this period. The first, "Medical Care in a

National Health Program," was adopted as the 1944 APHA policy in this field. The staff work on the joint statement on "Planning for the Chronically Ill," adopted by the American Hospital Association, the American Medical Association, the American Public Health Association, and the American Public Welfare Association in 1947, also was undertaken by this subcommittee. This statement, and the discussions which followed it, paved the way for the establishment of the Commission on Chronic Illness and for many official and voluntary chronic disease control programs. The third document which the subcommittee helped prepare was the "Coordination of Hospitals and Health Departments," adopted jointly by the American Hospital Association and the American Public Health Association in 1948.

Mountin's analyses of the complex medical care question, both as an individual and as a member of the APHA subcommittee, were characteristically years ahead of his time. He was writing on this problem and the responsibilities of health agencies in a medical care program long before most health workers were conscious of the essential interrelationship.

The health department, by virtue of its experience, competence, and specialized knowledge, he saw as the logical organization for administering a medical care program. Repeatedly, however, he warned that few health departments were ready to do so—as in the following, from a transcript of a medical care training conference called by the Public Health Service in 1946:

"They [health administrators] shun responsibility. They give the impression that they have no interest in medical administration and show no disposition to accept responsibility in that field and all the time they are being pushed aside and these medical care programs are being organized under other auspices."

Mountin constantly pointed to the great opportunities which health officers have if they are willing, in the words of Dr. Oliver Wendell Holmes, "to shake the dust out of their traditions." He never lost sight of the ultimate goal of all health programs—to bring better health and greater satisfaction to each person in his

home, on his job, and in his community. There was no dust in his thinking.

A Great Forerunner

Ralph Waldo Emerson once said: "The measure of a master is his success in bringing all men round to his opinion 20 years later." Mountin was such a master. We who worked with him knew that he was always thinking ahead, anticipating needs, planning what public health should be doing in the next decade. In 1931 he was urging exploration of the relation of housing to health (12) and the next year he called for (13) "A modern public health program . . . directed against cancer and heart disease and . . . [promoting the] mental hygiene and the health of workers in industries."

At the time of his death, his thinking was reaching fruition in plans for chronic disease control and the hygiene of aging, involving as they do a confluence of medical, social, and economic factors. Along with the provision of adequate medical care for all the people, they represented to him the next goals of public health.

In his view, the only boundaries to our responsibilities were those of our own imagination and ingenuity. Everything that affects health, Mountin maintained, should be the concern of the health worker; and the health worker should be anyone who has anything to offer that will improve human well-being. To him that meant that public health could never be satisfied with anything that is static or outmoded but must concentrate on unmet needs and problems.

In consequence he stimulated, persuaded—goaded if necessary—others to raise their sights. He carried this message to organized health agencies especially. "All too often, health departments merely meet situations as they arise or carry on stereotyped programs handed down from predecessors." These words may sound like an abstract of his latest papers; actually, they were written (14) in 1928. This was a theme that he sounded, now as a prophet, now as a judge, throughout his professional career. For he firmly believed that public health belongs "by hereditary right . . . in the vanguard of social action" (15).

Perhaps his outstanding contribution was that he brought to public health an amazing breadth of comprehension and vision. He made us aware that public health is the study and application of many sciences in the interest of human health set in a matrix that is at once historical, social, economic, political, and cultural (16):

"Public health is an applied technology resting on the joint pillars of natural science and social science. For the past century the natural science foundation has been magnificently strengthened—strengthened to the point that we now have the technical knowledge to eradicate or reduce greatly much of the misery to which man has been heir. Yet vast amounts of preventable or controllable disease and disability remain, because the social science foundation is relatively weak. Until both the pillars of natural and social science are strong, the arch of public health will not be firm."

Dr. Joseph Walter Mountin was a man of varied talents and unusual abilities. He goaded us; he challenged us; sometimes he bewildered and exasperated us. Yet if public health really is in the vanguard of social action, if health is now considered in a broad socioeconomic context, thanks are due him and a few other pioneers. His contributions to and effects upon the Public Health Service will be long remembered. But his contributions belong not to one organization alone but, rather, to an entire field of human endeavor.

ACKNOWLEDGMENT

The author desires to express appreciation for the assistance of many associates and friends of Dr. Mountin in the preparation of this article.

Financing Local Health Services

By JOSEPH W. MOUNTIN, M.D.

The future of Federal support for local health services is difficult to prophesy. On the one hand, the future appears to hold a progressive increase of appropriations for bigger and better health units; another view points to a drying up of the streams of Federal funds, with the future of local health units in the lap of the gods—the State and local appropriating authorities. Possibly both of these views are partially correct. In other words, we may well have an increase in the flow of funds which will help sustain a material growth of local health services, but only after an indeterminate period of drought.

Public Awareness and Demand

The prediction of Federal support for bigger and better local health units is based in large part on the clear and steady growth of public awareness of what good community health can mean in terms of total well-being and long-run economy. The American people have learned to value good health as a positive resource and to ask for those things which will protect and improve that resource. This is evidenced by the importance given to building good health into almost every aspect of our daily life. We see it, too, in the increasing number of com-

munity health councils and in their vigorous programs that emphasize cooperative planning and action.

One example of this popular interest is the strong and united support given by many groups—professional, voluntary, and citizen—to the local health unit bills which have been under consideration by the Congress since 1948. One of the bills was passed unanimously by the Senate in 1949 and was recommended favorably by the House committee in that year, but did not reach the floor of the House for debate. The Senate again passed a similar bill last year, but to date it has not been reported out of the House committee. These bills, like other domestic measures, have been slowed down by the momentum of defense and international demands. But we can all take courage from the unanimous agreement on the objectives of the bills: to strengthen local public health services in all areas of the Nation through the development of sound administrative units with adequate staffs.

The proposed local health bills would make grants-in-aid available to States to be used only for the provision of local health services. This differs from existing grant authority, under which the State agency may determine, subject to approval of its plan by the Surgeon General, whether grant funds will be used to support State-administered services or be used for locally sponsored services. The proposed bills would provide for Federal financial support to cover a portion of the cost of local health services in each State; and Federal participation would be contingent upon a definite State plan for eventual extension of local health services throughout that State. The percentage of Federal share in these costs would vary from

Dr. Mountin was chief of the Bureau of State Services of the Public Health Service at the time of his death on April 26, 1952. This paper, his last formal address, was presented before the first general session of the Southern Branch of the American Public Health Association at its twenty-first annual meeting in Baltimore, Md., April 17, 1952.

State to State, depending upon population and per capita income of the State compared to that of the United States as a whole.

Questions have been raised about the sharing of costs and the defining of public health functions. These controversial issues will be considered later. But first let us examine the significance of the wide-ranging agreement on the need to extend and strengthen local health services. What events, influences, and experiences have persuaded so many people and so many groups that well-organized and well-staffed local units can best serve community health, and that more such units need to be encouraged and supported? From this background, perhaps some clues can be found as to how and when prediction might become reality.

Federal Aid and Local Services

The enactment of the health sections of the Social Security Act in 1935 marked a milestone in public health history. The grant-in-aid mechanism authorized by that act has served as a bridge for bringing to many communities the resources they need and lack, and for equalizing the financial burden. Federal grants for public health services have worked toward the following objectives: (a) to establish a working partnership of Federal, State, and local governments; (b) to equalize State and local ability to provide services; (c) to make possible a concentrated attack upon specific health problems; and (d) to preserve local autonomy and initiative while strengthening the services made available through local efforts. To a considerable extent, these objectives have been realized. Whether coincidentally or as a direct result of Federal assistance, local health services have been widely extended during the past 15 years, the period in which Federal aid to States and communities has been available. Geographically, at least, there has been fair success in the establishment of organized local health units. The number of counties served by these units has more than doubled since 1935, having reached 1,542 counties in all. These counties are the more populous ones.

The Federal-State-local partnership has proved to be a stimulating one, and one which produces a fine feeling of solidarity. It has

become a channel for exchange of ideas and exchange of personnel. From its wider resources, the National Government can lend supplementary personnel and contribute particular services to local communities either in lieu of, or in addition to, cash grants. It can translate new scientific knowledge into public health practice and, through on-the-spot consultation with State and local health authorities, can adapt this new knowledge to the special needs of communities. Through its corps of consultants in the several public health specialties, it can assist in the development and improvement of the content of local health services.

The record is eloquent also with respect to the Federal Government's interest in specific health problems. Grants for special health purposes have encouraged concentrated attack upon particular disease entities. New health programs have been initiated and old programs revitalized. Health problems to which Federal aid has been addressed through the categorical grants have responded well to intensive programs. Control of tuberculosis and the venereal diseases is at the most effective level ever known in this country; malaria has been virtually eradicated; infant and maternal death rates have been dramatically reduced. Hospital construction grants have brought about expansion of much-needed facilities.

In general, we have seen a remarkable improvement in the health status of the Nation. Of course, no one is satisfied to stop at this point, nor should he be. Many problems are yet to be solved, and their solutions in many instances would entail an outlay of funds in larger amounts than are available in present budgets.

A New Base of Services

We must remember that public health concepts apparent to us now had not emerged in earlier days or were crowded out of our perspective by the multiplicity of primary problems which had to be met. The pace of progress has brought us to the realization that today's health needs cannot be met with an organization and type of service geared to an earlier set of problems. The changing character of community health services demands a broader administrative structure and a wider range of professional

competencies. In the beginning, public health physicians, nurses, sanitarians, and laboratory technicians made up the staff. The demands on this team of organized workers have gradually expanded to require the addition of health educators, dentists, dental hygienists, veterinarians, and statisticians. Today, a great variety of specialists—cardiologists, pathologists, psychiatrists, psychologists, medical social workers, nutritionists, and even anthropologists—have a place in health service programs.

In addition, a number of new kinds of facilities are now necessary. Among these may be mentioned diagnostic clinics, X-ray facilities, and other case-finding devices.

Unfortunately, many small political subdivisions simply do not find it possible to provide the multiplicity of facilities, equipment, personnel, and funds which may be necessary. Then we must ask: "How local can a local health unit be without loss of effectiveness and without impairing its financial base? What services must be included if it is really to influence health under present conditions?" A sparsely populated rural county or a single township can usually provide such traditional health services as improvement of sanitation, performance of immunizations, and giving advice to mothers on how to rear healthy children. A larger, more rational type of local health unit, with more extensive resources, is required for such services as screening tests for chronic disease, mental and school health programs, and rehabilitation of handicapped persons. In many instances, local governmental jurisdictions must combine if they are to become functional areas which can provide the newer health services.

One still hears emphatic statements to the effect that political units cannot be merged. This is quite contrary to the fact insofar as health administration is concerned. Practically all county health departments serve from several to all of the incorporated municipalities within their boundaries. And of the 1,542 counties receiving the benefit of full-time local health services, about half are in health districts combining two or more counties and municipalities.

This trend is encouraging, but it does not extend far enough. On the other side of the pic-

ture, we see that 37 percent of the full-time health units now in operation serve a population of less than 35,000; 59 percent serve areas of less than 50,000 population. Generally, such jurisdictions represent too small a base for administration of up-to-date public health programs. More than half of the units still serve single counties only. This situation is reflected in their serious staffing deficiencies. Only 6 percent have enough nurses, 35 percent enough sanitation personnel, and somewhat less than half have sufficient physicians to meet minimum requirements recommended by professional health organizations.

There are still between 35 and 40 million people living in areas without organized full-time local health services. However, this represents only one phase of the need; in fact, as far as nominal coverage is concerned, the record is not too bad. Of much greater concern is the fact that many local health departments now have only skeleton staffs and serve areas too small for either economical administration or comprehensive service. They cannot afford the kind of organizational framework needed to initiate community activity which will result in all needed services being made available.

Some of these difficulties must be resolved by legislative or administrative action taken within each State. A number of States still lack enabling legislation for the establishment of multicounty or combined city-county local health units. Other areas, although they have such legislative authority, have been slow to reorganize on a broader base. Part of this reluctance lies in the fear of losing local identity and autonomy in the process. Actually, the best assurance of local autonomy lies in so organizing local institutions that they will serve the needs and desires of the people.

These, then, are the facts which clearly indicate the need for a broader basic framework of local health organization than we now have. To hasten this achievement and to provide stability, Federal grants for local health services must not only continue but also increase.

Status of Federal-State-Local Partnership

However, instead of progressively measuring up to the new demands and concepts, Federal

grants for general health services have leveled off. The general health grant has decreased slightly in dollar amounts each year since 1950; in purchasing power it has declined materially. Furthermore, relatively little progress has been made in extending local health services during the past 3 years.

Why has this leveling-off occurred? Is it because of inflationary fears, the clamor for tax reduction? Is Federal aid for local health services no longer needed? Is it because our Federal monies are so widely needed elsewhere in these troubled days? Is it because changes in public health problems and principles now demand a different fiscal approach? Certainly there are divergent opinions on the how and why of Federal aid in this field. This may be the time to try to crystallize the varying opinions into constructive thinking and action to move beyond the plateau.

It seems philosophically significant that the leveling off of Federal assistance for general health services has been accompanied by the initiation of additional grants for special purposes. Many public health workers, as well as segments of the general public, have felt that this specialization is proper and wise. Other public health administrators feel equally sure that endless difficulties are caused by the increasing number of categorical grant funds, and would like to see such grants absorbed in a larger general health grant.

No matter how we look at categorical grants, no one can deny the remarkable influence they have had in sparking public interest in health. Specialized grants have captured public imagination in a way that could not have been easily accomplished under general grants. From the financial viewpoint, however, categorical grants can lead to burdensome accounting requirements on all government levels. They also carry the potential handicap of too much rigidity in that they might work against the redirection of money and efforts as health needs change.

It is not certain whether a new and different fiscal approach is needed. Part of the answer must come from the people who administer the services to the ultimate users. I do believe we have a sound pattern on which to make the adjustments that may be necessary

and the kind of partnership which will make the adjustments work satisfactorily.

There are some who feel that the Federal-State-local alliance may be an unholy one. In their reluctance to see further extension of Federal aid to local services, supporters of this point of view seem more concerned about theories of government than about the actual realities of operation. Nevertheless, honest criticism can be highly constructive if we will so accept it and will consider the questions raised as a challenge. Even those of us who are the most enthusiastic advocates of our present system do not claim perfection for it. Unquestionably, some changes are needed if local health services are to expand beyond the point at which we now find ourselves.

There are also those who take a fatalistic view and say that expansion of local health programs cannot be accomplished, no matter how much financial assistance is available, because of severe personnel shortages. That there is a serious shortage of public health personnel is undeniable. However, some health departments have been able to recruit and train staff to fill their vacant positions and to utilize auxiliary personnel effectively within a professional staff. The key to their success appears to lie in an adequate budget. Local health departments must be in a good position to attract and hold qualified personnel. Adequate pay and suitable conditions of employment are of paramount importance. Although there has been steady improvement in the salary schedules for public health workers, the rate of increase has not been sufficient to keep up with the inflationary spiral, to say nothing of competing favorably with outside demands for professional services. Given a larger budget, readjustment of salary schedules would be relatively easy. Likewise, it would be possible to step up training programs in order to establish a larger reserve of qualified personnel from which to draw.

Possible Alternative Approaches

Simply augmenting the present scheme of Federal grants for general health purposes would not, of itself, assure the needed expansion in local health services and personnel. Al-

competencies. In the beginning, public health physicians, nurses, sanitarians, and laboratory technicians made up the staff. The demands on this team of organized workers have gradually expanded to require the addition of health educators, dentists, dental hygienists, veterinarians, and statisticians. Given a larger budget, readjustment of salary schedules would be relatively easy. Likewise, it would be possible to step up training programs in order to establish a larger reserve of qualified personnel from which to draw.

Possible Alternative Approaches

Simply augmenting the present scheme of Federal grants for general health purposes would not, of itself, assure the needed expansion in local health services and personnel. Al-

though this grant has many advantages in that it can be used for a variety of purposes at both the State and local levels, its very flexibility permits the State to concentrate a large proportion of the funds in the State agency. Only 36 percent of the \$13,500,000 general health grant now available annually is being used to support the basic local health structure; 64 percent is expended for State-administered services. When all Federal funds (categorical as well as general) are considered, only 23 percent is spent by local health departments. Up to the present time, this has been wholly justifiable in order to build up the needed State strength. We must also remember that much of the State spending directly benefits local communities, as in providing laboratory services, operating mobile X-ray units, and the like. One reason that the State agencies perform as much direct service as they do, however, is the necessity to compensate for services which are not available through local auspices. This gap must be filled by local departments before many State services can safely be reduced.

To assure local use of Federal aid, we probably need to specify that such aid must be used only for the development and support of locally sponsored health services. Because public health problems are never static, local health services supported by a grant of this kind should be broad in scope. A narrowly circumscribed Federal definition of the exact services which could be supported would add greatly to the complexities of administration and accounting. In the long run, too, it very likely would have a limiting and even interfering effect on the content of local programs.

If a general-purpose grant to be used exclusively for local health services were made available, its relationship to remaining categorical grants would have to be determined. I do not anticipate that aid for general local health services will replace the need for limited grants directed toward special problems, since it would be designed primarily to supply those fundamental services necessary for the operation of all programs. Maximum benefits from a general-purpose grant for localities would be derived only if it were made available on a continuing basis. Without reasonable assurance of permanency, health departments would con-

tinue to find it difficult to establish and maintain the kind of facilities they need and to recruit essential personnel.

It is entirely possible that we may be forced to resign ourselves to remaining on a plateau until times are less stringent insofar as Federal funds may be involved. There are still difficulties ahead for Federal participation in local health services. Because of the declining value of the dollar, aid at our present level will accomplish less than it has in the past. Prospects are not too good for increased Federal participation because of the financial position of the Federal Government at this time. Demands for defense activities and international obligations, as well as divergent theories of the proper role of the Federal Government, all contribute to a hesitancy to assume any greater support of local functions.

The Long View

In spite of all the seemingly adverse factors, the future still appears rosy, for at least three reasons: First, the people of this country are decidedly interested in, and conditioned to, good public health, not only for their own but for neighboring communities; second, the newer concepts of public health are too promising to be long denied; third, it seems reasonable to assume that international tensions will taper off over a period of time although perhaps not so quickly as we should like. In the event, however, that such tensions increase to the point of all-out war, then, of course, all predictions must be cast aside.

Thus, we come to the realization that there are potentialities over which we have no control. But to a certain extent, we can make the future, and on that premise we ought to set our minds and our sights at this time so that we may move ahead logically and positively when circumstances permit. It is incumbent upon us as public health administrators to stretch our present resources as far as possible, and at the same time to plan optimistically for the future we want. We need not wait for additional Federal aid to start consolidating some of the smaller and weaker units for better utilization of available personnel and facilities. Account can be taken of newer health problems and

methodology and plans prepared for gradually drawing them into the orbit of activities. Each State and local health officer can now critically examine the services of his department with the purpose of developing a coordinative and State-wide pattern which will make every use of local resources and initiative. Imagination can be applied to personnel recruiting and training problems.

Now is an ideal time for this kind of thinking. It has been demonstrated that we are in agreement on the need for expanded local health services. We are aware of the elements which have worked well so far. We have a solid background of experience and knowledge which we can apply to solving the problems before us. And that is the kind of combination which seldom fails when properly used.

Community Health Services for an Aging Population

By JOSEPH W. MOUNTIN, M.D.

One of the great emerging opportunities for public health is health services for an aging population. I am convinced that there is a great new field here for the public health profession, one that is different, more complex, perhaps more experimental than any we have known heretofore. By the same token, however, it is one which offers great rewards to the profession as well as to the community and the Nation.

The current interest in aging is shared by a great many professional and community groups. This interest is a reflection of the problems which strike deep in the hearts and minds of millions of people in this country. Certainly the vast majority of us can expect to face the hazards—and the satisfactions—of aging. Because of the conquest of the diseases to which public health programs hitherto have been addressed, more and more people will live

into a period which not so long ago was regarded as very old age. They will have to face the problems of adjustment, of health, and of security that later life brings. For most people, the interest in aging is very personal and very real.

To a considerable extent, therefore, people are waiting for professional groups to take the lead in establishing suitable programs of action. Herein lies our great opportunity—to make the added years really worth while by helping older people remain productive members of society.

It would probably be repeating the obvious to go into the background of the problem or to belabor the point of its significance. The fact that we had four times as many people over 65 years old in this country in 1950 as we had in 1900 is too well known to need emphasis. Present population forecasts indicate that by 1975 there will be more than three people over 65 for every two now in that age group.

Part of the explanation for the increasing community concern can be found in the very numbers themselves. Too many people are involved, both numerically and proportionately,

Dr. Mountin delivered this paper before the Tennessee Public Health Association at its annual meeting in Nashville, March 25, 1952.

for society to remain aloof or uninterested. Part of the explanation also lies, however, in changes in our economic and social life. We are beginning to recognize that our traditional patterns, customs, and attitudes simply make no place for older people today.

I shall not go into the social and economic aspects of the problem, except to note two points: their intimate relationship to health—for the older person particularly, it is often difficult to determine where a social problem ends and a health problem begins; and the job of changing attitudes—breaking down old prejudices and fixed habits is as much the responsibility of public health as is the provision of case-finding or home-nursing services.

Health Needs of Older People

What are the health needs of older people and what can the community do toward meeting them? The needs are, in fact, no different from those of all of us: to stay well or to preserve health insofar as possible; to get prompt and effective care in the event of illness; and to regain normal or near-normal function following disability. There is another need, which is really an amplification of these three, and which makes the health problems of older persons unique. Aging persons must be encouraged to retain, to conserve, and to use all their resources, whether they are nominally free from disease, whether they are victims of a long-term illness, or even whether they are in the advanced stages of what we consider old age. They must make the maximum use of remaining capacities, however limited, if they are to realize their full potential.

This implies a positive, rational, optimistic approach. It is an approach consistent with the new concept of aging as a phase of development rather than as a period of complete deterioration. It is consistent, too, with the wishes of older people themselves.

Aging is not in itself a disease nor is it necessarily accompanied by any specific disorders. We should also bear in mind that the potential span of man's usefulness and productivity has increased along with his lengthened life. The later years need not all be declining years.

At the same time, aging does bring physical

changes and a decrease in physical strength and resiliency. Long life also increases the possibility of the development of a chronic disease. And, according to present knowledge, once a person acquires a chronic disability, he will probably have to live with it for the rest of his life. The extent to which health is maintained in the later years depends a great deal, therefore, upon how health needs are met in the earlier years.

This leads to an important principle in health planning for the aging. A health program for older persons cannot start at 65 or any other given age. It must begin long before the deteriorations are marked and irreversible. It must make provision for preventive and preparatory measures throughout the span of adult life. In other words, the emphasis must be on adult health and on strengthening the health services which will enable all people to prepare for later life.

Another element that must be considered is the extreme variation in health that is found among older people. Aging is a highly individual matter, as is the propensity for disease and the severity of its effects. We all know people who are old at 45 and those who are young at 75. Less well known is the fact that we may be old in one part of our body and relatively young in another. This inconsistency in rates of change accompanies physiological processes throughout life, but it is more pronounced in the later years.

Because the health needs of older people are so varied and complex and because they are so heavily weighted by social and emotional factors, they may be met through resources far outside the traditional health setting. For example, suitable housing accommodations for the displaced elderly person may be as important in the total health program as physical facilities for care of the sick. Gainful employment which will enable the older person to participate in community life may do much more than diagnostic clinics or nursing homes for the aged. In many instances, the older person may simply need financial or legal advice to see his emotional and even his physical problems begin to wane.

Older people who become ill take longer than others to get well. This problem of extended

convalescence must be considered a special element in health planning. Rehabilitation and restorative services of many kinds—medical, vocational, psychological—thus assume an important place in community health services for the aging. Public health agencies should work with nursing and convalescent homes to raise standards and improve the quality of care. They might also promote and develop rehabilitative services in community hospitals and health centers.

To most of us, rehabilitation evokes the thought of elaborate facilities and expensive specialized equipment. Yet a satisfactory, if elementary, type of service can be developed with the use of one room in a health center and the professional services of only one or two people. Even with the aid of the simplest equipment, installed here and in hospitals and nursing homes, many older persons could recapture skills lost during illness or learn to live with a disability. In other words, the development of a point of view should precede the installation of extensive equipment.

Local Approach Needed

The question of how best to meet the varied needs of older people has been the subject of considerable discussion in recent months. Such meetings as the 1950 National Conference on Aging and the Second International Gerontological Congress in September 1951 were held in recognition of the importance of an organized attack on the problems of the aging. To a considerable extent, however, the problems can be answered only by local communities, in terms of their own particular needs and resources.

I would, therefore, lay down no blueprint of community health services for the aging. In fact, it is well nigh impossible to set down a specific program, or a set of programs, and say these would be applicable in all situations. What a community does, or can do, may be dictated by a number of considerations—the extent of the need, the amount of local awareness and popular support, the number of physicians and other health workers, the kinds of physical facilities available, and the assumption of

leadership by professional and community groups.

Because of the complexity of the needs, no single community agency can by itself provide all the health services that may be necessary, to say nothing of the equally important economic, social, educational, and recreational services. Both official and voluntary organizations have important jobs to do. In fact, without the help, the stimulation, and the leadership of voluntary and professional groups, we can expect little in the way of concrete action.

What then are the responsibilities of the public health agency? As a first step, it should begin to gather and put to work the knowledge that has already been accumulated about the problems of aging. In general, the health department has two sets of jobs. It must take its place with the other organizations in the community—both official and voluntary—in working out a coordinated approach to the many needs of older people. And it must provide certain specific services in the field of health. These services might include the establishment of health guidance clinics for older people in a manner similar to the health clinics for mothers and children; the conduct of control programs for such chronic ailments as heart disease, cancer, diabetes, arthritis, and the like; the dissemination of suitable health education material; and the inspection, licensing, and improvement of nursing homes, foster homes, and other facilities for the disabled or infirm aged. The long-term interests of older people, as well as of the entire community, will best be served by a health department that affords the essential framework through which organized programs can function effectively.

Role of Professional Health Workers

What are some of the specific contributions to a program for the aging that can be made by various types of health workers? The public health nurse, to take one example, can play a very strategic role. Because the nurse knows families and their needs, she is in a very good position to help them make necessary adjustments and arrange for the correction of disabilities. Visiting nurses particularly have the opportunity to assist the family in learning the

skills necessary to care for ill or infirm older persons. In addition, bedside care should be increasingly included among the services provided by community nurses. In cooperation with other groups, nurses can advise families on how to simplify household tasks, plan and prepare adequate diets, avoid home accidents, and maintain a cohesive family relationship.

Many environmental health services may be reoriented to the needs of older people. Public health engineers, for example, may find it desirable to evaluate the home and working environments in terms of adjustments that might be necessary for an aging population. They might develop standards for the housing of older people. And they might work with police and traffic authorities to eliminate health hazards in the streets and to make travel on buses and street cars safer for the aging.

The problems of older people open up great opportunities for psychiatrists, psychologists, and other mental health workers. Growing old calls for many mental and emotional adjustments. Often it is fraught with traumatic experiences. We all realize that the transitions from a dependent to an independent status—such as from childhood to adolescence and from adolescence to maturity—are delicate ones. These can be periods of emotional stress and turmoil. The adjustments made necessary by the older person's reversion to a dependent or semidependent status are just as trying—perhaps even more so. In fact, this is the very time when suicide rates go up and when mental deterioration sets in. Yet most mental health programs are directed almost exclusively toward the child and the youth. Certainly mental health clinics and counseling services should set aside some time for meeting the needs of older people.

Perhaps the most outstanding opportunities for fruitful work with older people may be found in the field of health education. Undoubtedly the skills and techniques of health education can find a significant outlet in work with the aging. Education must not only arouse popular and community interest but must succeed in motivating older people to do things for themselves. Health educators, probably more than the rest of us, will be aware of the fact that we are working with as well

as for older people. Because the older person generally has the best understanding of his own needs and because he has the ability to make his own decisions, he must be drawn in on the planning and development of suitable activities. He must neither be patronized by nor segregated from the rest of society.

A Community Makes a Start

Briefly and in very broad outline, here are the steps one community is taking to meet its problems. As a result of interest stimulated by the National Conference on Aging and the thinking of prominent citizens in the community, a general committee on aging was set up. On this committee are represented some of the official organizations in the county such as the health and the welfare departments; voluntary groups like the community chest, church organizations, and clubs of older people; and individual citizens. The committee is entirely voluntary and without official status. Nevertheless, it is a nucleus of understanding and competence and is spearheading the development of an ambitious community program for older people. Moreover, it is having a decided effect on the county's health and welfare programs and on the work of nonofficial groups.

One of its first activities was to conduct a survey of the older people in the county—their sources of income, health status, living arrangements, and interests. Out of this survey, the committee is beginning to establish guidelines for its next steps. The problems uncovered in this survey will also help the committee decide the nature of its permanent organizational structure and its budget and staffing needs.

In the meantime, however, the group is going ahead with such activities as it is able to start on its own, utilizing whatever resources are available. The surprising thing, perhaps, is the number of projects that have been started and the heartening cooperation that has been obtained. For example, the committee has stimulated "friendly visitors" services for the homebound aged, has sponsored a hobby show and recreational activities for older people, has prepared a column on aging which appears regularly in the county newspaper, and has worked with local church leaders in developing

suitable activities. Through the efforts of this group, a local banker has agreed to give financial advice to older people. Several physicians have begun to develop a special interest in geriatrics. All of this has taken place in a little over a year and with no special budget.

The community health agency has taken a prominent role in organizing this committee and in guiding its development. As suggested earlier, this is one of the ways in which the health department can become a part of a general community aging program. On the other hand, it can also launch adult health activities by conducting specific chronic disease control and related programs. Both approaches have advantages. The latter has the advantage of

specificity and of utilization of the traditional experiences and competencies of health workers. The former meets the needs of the aging group on a more integrated front and provides the supporting services which enable a health program for older people to reach full effectiveness.

Eventually, of course, both methods of attack must be pursued. But the important point now is that some start be made. To be sure, public health cannot yet supply all the answers, nor meet all the needs. But it can make that start. And in doing so it can earn the gratitude and respect of older people by making an important contribution to a better life in the later years.

Public Health Nurses

More than 25,000 nurses are now engaged in public health work, according to the Fifteenth Annual Count of Nurses in Public Health, recently prepared by the Division of Public Health Nursing, Public Health Service. Although there is still a shortage of public health nurses in every State, the number has increased more than 4,000 during the last 5 years.

It is estimated that an additional 12,000 to 15,000 public health nurses are needed to meet current shortages. The 1952 Census shows that

rural areas in over 650 counties still lack the services of full-time public health nurses. Thirteen towns of 10,000 or more population are also without such services.

The 1952 count of nurses also indicates that more than 35 percent of all nurses employed by State and local agencies for public health work have completed an approved program of study in public health nursing. In 1942 less than 28 percent had this training.

There is no similarity between the clinical manifestations of the onset of cancer of the lip and cancer of the rectum, and there is the same enormous variation in the mode of exodus of the patient. Cancer of the breast may terminate with metastases to lungs and to bone and present problems of management completely at variance with, say, the patient whose cancer of the stomach is followed by nutritional problems, cachexia, and terminal hemorrhage. Between such extremes lies the spectrum of terminal disease, made extremely broad by the many anatomical sites of cancer and the many degrees of growth activity included in the term "cancer." Technically, terminal care begins at that moment when it is accepted, after careful study, that the patient's disease cannot be controlled.

"Calls for" Services

For the purpose of considering professional attitudes "terminal" may be defined broadly as that period in the course of cancer which is characterized by progressive invalidism that calls for professional or quasi-professional services, given regularly and frequently.

That part of the definition which bears most directly on professional attitudes is the phrase "calls for professional or quasi-professional services." The term is not "requires" as in emergency complications about which there is no question of the importance or value of professional attention. It is not "demands" in the sense that the patient with superior resources accepts, pays for, and gets the best medical, nursing, and custodial care.

The simple, almost homely, phrase "calls for" best expresses the needs of a large segment of those patients with advancing cancer—those who depend on the service of the general practitioner and whatever ancillary ministrations their dwindling resources permit, and those who, through gradations of indigency, must look to public welfare and to voluntary agencies.

The fact is, today, that response to this need is remarkably diverse. I have recently been impressed by this diversity during a visit to two city cancer hospitals. One is a new building associated with a large cancer center and a teaching hospital. The second is one of those

which are called "cancer hospitals" but appear to descend from the era of the pesthouse. In the first hospital an enthusiastic and zealous staff conscientiously fights and overcomes the attitudes of despair, frustration, abandonment, and rejection which abound in the second hospital where the terminal cancer patient is barely endured as a hopeless, helpless, and frequently unpleasant problem for whom routine, uninspired, and often cursory custodial care is doled out. An understanding and appreciation of the final outcome of inoperable, incurable cancer should not preclude a lively struggle on the part of all concerned, including the patient himself, to preserve integrity and maintain the best possible physical status until the final and overwhelming onslaught of disease.

In the first hospital, research along many fronts is under way, and active treatment for all patients is the rule. I do not believe that research activity alone is responsible for the encouraged attitude of the patients, but I do believe that the attitude of those who care for these patients—doctors, nurses, social workers, recreational workers, and volunteers who help perform a myriad of tasks—is all important. Such attitudes of professional personnel are not limited to facial expressions, tone of voice, conversational content, or even to expressions of extraordinary interest in the patient's welfare. More importantly, I believe, such attitudes are expressed in active treatment which assures and convinces the patient that he has not been abandoned. Each new complaint, each succeeding sign of deterioration is regarded not as an indication for increased use of morphine sulfate but as a challenge to professional skill and an opportunity to relieve or ameliorate distress.

Response to Nutritional Improvement

That a great deal of the cancer patient's distress can be relieved is not wishful thinking. It can be accomplished by the intelligent and confident application of what we now know about the care of these people. We can improve their nutrition and watch them gain in weight and in morale. Patients with malnutrition all suffer anorexia, which in itself sustains the mal-

nutrition. No amount of encouragement or coaxing induces these patients voluntarily to consume the necessary caloric requirements. For many of them, the institution of tube feeding for certain periods of time is life-preserving. They will show rehydration, a gain in weight, and then to some degree an increase in strength. These gains will be followed by a return of appetite. Tube feedings may then be stopped and the patient will continue to eat substantial quantities of food. Subsequent to this, serum albumin and hemoglobin levels increase. The length of time necessary for restoration of appetite following institution of tube feeding is roughly proportional to the degree of existing malnutrition and varies from 1 to 6 weeks, with an average of 2 to 4 weeks. Elman of St. Louis has recently shown the advantages of aggressive dietary regimens, and to him I am indebted for permission to cite the following examples:

N.B.: 46-year-old female, diagnosis carcinoma of cervix, stage 4. Initial diagnosis in 1942; became stage 4 in 1950. Prior to patient's coming to us, she had weight loss of 40 pounds, anorexia, nausea, and vomiting, and was bedfast. Hematocrit 28; serum albumin 3.3. Tube feeding was instituted and continued for 36 days. At the end of this time she ate voluntarily 2,800 calories daily. At this time she showed a 16-pound weight gain, was ambulatory, felt much improved, and was completely free of symptoms. Narcosis was no longer necessary. Hematocrit 38; serum albumin 4.1. At this time she returned to her home ambulatory, taking care of herself, participating in family affairs. At the end of 6 weeks patient became moribund because of cerebral hemorrhage (probably secondary to metastases).

L.C.: 71-year-old female; diagnosis carcinoma of cervix, stage 4. Above diagnosis made in 1949. At time tube feeding was instituted, patient had lost 36 pounds, was bedfast, had anorexia, and was extremely weak. During one week's observation she ate practically nothing voluntarily, even with encouragement. After tube feeding for 49 days, she had regained 23 pounds, was ambulatory, free of all symptoms, and not taking any narcotics. She was hungry and able to take 3,400 calories from the tray. One week later she was discharged to her home able to care for herself and participate in family affairs. In the past 5 months she has gained another 35 pounds, is working, and is asymptomatic.

These illustrate clearly the difficulty in defining any hard and fast answer to the question "what is terminal?" And they underline the importance of sustained, aggressive treatment.

The Physician's Attitude

Some representative attitudes of physicians toward terminal cancer may be illustrated by several selected vignettes. The attitudes of physicians, I believe, condition the outlook of all persons on the professional team—nurses, technicians, social service personnel, dietitians, and occupational therapists. But all must share in the effect of the attitudes on patients and others.

Dr. A is by nature reticent and introverted, and is almost as depressed in the presence of cancer as the patient. His experience has deepened his instinctive gloom—having to care for a few terminal patients each year has been heavily dispiriting. His philosophy of "what's the use?" virtually atrophies scientific initiative and action. He does as little as possible—and offers irrational excuses for his inertia.

Dr. B's basic attitude is similar to *A's*. However, he hides a distaste for terminal cancer behind a mask of magnanimity. The essence of his philosophy is: "There is nothing I can do, therefore, it is unfair of me to come here day after day and take your money." Thus, he palms off his lack of interest and resourcefulness as a virtuous unwillingness to accept money under conditions where he can do no good.

Dr. C is kind, sympathetic, cheerful by nature. However, he has little intellectual or scientific interest in clinical cancer. But he tries to make up for his technical inadequacies by pulling out all the stops of his personality. The result is that the more critical the situation grows, the more jovial he becomes. This is fine while it lasts, but the truth is that most patients with cancer, which grows harder to bear each day, sooner or later conclude that this daily 10 minutes of optimism and encouragement is hardly enough for 24 hours.

Dr. D was brought up in a stern stronghold where honesty, frankness, and candor were esteemed above all other traits. He is the opposite of *Dr. C*. He believes that the major problems of terminal cancer can be dissipated by telling the patient the brutal truth, and does not recognize that what is one man's meat is another's poison. The delicate nuances of neurosis are weaknesses to be suppressed by any self-respecting patient and ignored by any self-

respecting physician. He insists that his practice of telling the patient the facts will correct the egocentric unbalance of a lifetime. Although he does help some, he does about as much damage as he does good, as is the case with anyone motivated by an inflexible dogma.

Dr. E. is thoughtful, studious, yet also considerate and understanding. He appears to the patient and the patient's family to show the same fresh interest at every visit. He obviously wants to visit the patient, and he treats each new difficulty as nothing more than a nuisance which needs to be abated, and which will be, if he has anything to do about it. Above all, the fundamental thesis of his approach is: "There is practically nothing that can happen to the patient until the moment of his death which I cannot engage and improve." More prosaically, he believes that while there's life, there's hope. And his conviction that he can make the rough places smoother is born of experience and study. He has at his fingertips eight different ways to make food more interesting to his anorectic patient. He knows five methods for keeping the patient's room free of odors from fecal drainage. His judicious and graded use of analgesics, narcotics, and hypnotics gives him means to counteract pain adequately, even for months on end, and he regards the routine use of morphine as admission of his own ignorance. He is informed as to the value of occupational and recreational therapy as means of converting a dreary, bored existence into a reasonable facsimile of interested, integrated living. He takes nothing for granted and the stronger the presumptive evidence of hopelessness, the more aroused is his therapeutic combativeness. He will not give up.

The feature common to the first three physicians was a lack of interest in terminal cancer—a state of mind which reflected itself in apathy and inaction. The fourth was mechanically resourceful and interested, but he spoiled it all by disregarding the all important attitude expressed in the word "tact." The final example combined inquiry, imagination, and persistence to the distinct advantage of the patient.

There is one grave danger in adopting the attitude of compromise in caring for any patient—even the patient with advanced and seemingly hopeless cancer. Such compromise may

become expedient at some point in the course of cancer. But where shall that point be designated? If it seems best to give up in one case, why not in the next? If prolonging life appears normally unsound in one case, will the same not hold in the next one? When shall the doctor and his team slacken their efforts? Who shall say when the battle is over? The danger is obvious: To reduce therapeutic effort at any time, under any circumstances, is to endorse partial "therapeutic nihilism." It is not an unattractive expedient. It saves work, and better yet, it saves worry. Of course, full commitment to that practice would save the doctors all worry—and incidentally, all work. Obviously, the safest and fairest therapeutic method is to regard every living cancer patient as susceptible of improvement.

New Agents for Pain Relief

This plea for continuous and unremitting interest in the problems of terminal cancer might, as recently as 10 years ago, have been regarded as an altruistic but quite unrealistic exercise. The advances of medicine, which began with World War II, have left little legitimate base for such a view today.

I have referred to the aspect of nutrition. There are others of importance. While few would claim that meticulous attention to fluid and salt equilibrium, protein balance, and vitamin requirements is as important in terminal case management as it is in the postoperative patient, it is still of first importance to the patient, whatever his status.

The pain of advanced cancer can often be controlled by the exercise of professional imagination and ingenuity, and at the same time the problem of drug dependence or addiction can be obviated or greatly lessened. Surgical nerve sectioning procedures, such as prefrontal lobotomy, chordotomy, rhizotomy, and nerve injection, have their places, and when properly selected can reduce intractable pain to bearable proportions. Dependence on morphine for pain relief over long periods is as regrettable as it is unnecessary. A dozen drugs are at hand. The thoughtful use of them in succession and in graded amounts will avoid the sledge hammer effect of morphine sulfate with its too

frequent result—personality disintegration. In one institution hypnosis is being explored as a means of pain control, and the early results are at least interesting. Pain in cancer is often an effect of infection in the tumor or its adjacent area. The control of such infections is frequently the equivalent of pain control. Indeed, in selected cases antibiotic and bacteriostatic agents are as effective as narcotics in achieving pain relief.

The prolongation of useful, comfortable life following administration of indicated hormones is well established. The place of chemotherapy as distinguished from hormone therapy is limited, yet within a narrow spectrum of usefulness a few drugs do accomplish unique results. Hodgkin's disease, sometimes lymphosarcoma, leukemia, cancer of the lung, and plasma cell myeloma are susceptible to one or another of the chemotherapeutic agents. Radioisotopes, while not living up to the hopes expressed for them 5 years ago, are, under special circumstances, the treatment of choice. The wider use of supervoltage X-rays and their application to tumors with new precision techniques, such as rotation of the patient beneath or before the tube, and the therapeutic use of other forms of high energy radiation, as the betatron, are bringing a greater measure of relief to those with inoperable advanced cancer. The psychiatrist and the clergyman can give some individuals the help which no amount of physical or medical maneuvering can, and the physician who would offer every possible benefit to his patient will be alert to these services.

All these things have narrowed the margin called "terminal." Yet their potential of usefulness is far from realized.

I plead for a perpetual spirit of inquiry toward the advanced cancer patient. We know little enough, and we are never justified in adopting a pontifical or complacent attitude as though the answer were known and the course of the disease adequately forecast. Obviously, danger lies in glib or routine predictions concerning how long a particular patient may expect to live, and the fact that such predictions

are so often wide of the mark sometimes leads families to question the competence of those who make them. It is important that the physician who accepts the responsibility for a patient with terminal cancer obtain a careful history covering the entire course of the patient's illness, and perform a meticulous and critical physical examination. Not infrequently a diagnosis of inoperable cancer may be made by one physician, whereas a colleague with perhaps more experience may find the cancer amenable to treatment with at least a theoretical chance of cure. Too, it has happened that a diagnosis of cancer was made when no cancer was present. Errors in interpreting X-ray films and failure to obtain pathological proof of the existence of cancer can account for mistakes in diagnosis and unwarranted hopeless prognoses. It is important that nothing be taken for granted and that each patient be afforded a critical review.

There is one additional reason why every patient with advanced and hopeless cancer should be sustained by the active interest and care of his doctor until the inevitable exodus occurs: to protect the patient, and his family, from the charlatans and quacks who invade the fringe of medicine and offer hope and promise where they are not justified. When physicians shirk or neglect the care of their advanced cancer patients, it is inevitable that the patients turn to those who hold out encouragement and promise. The harm done by these quacks is incalculable. Patients are defrauded of money and denied the comfort and sustaining care which should be provided by their physicians' interest and skill.

More experience, more research, and more time will bring still other and more effective support and relief to the cancer patient in the terminal phases of his disease. But they will come, as all medical progress has come, only to those with minds which are actively seeking any and every means to improve a seemingly hopeless prospect. They will never come to the mind resigned to the inevitable.

Typical Patient and Family Attitudes

By ADDIE THOMAS, M.A.

The patient's reaction to terminal cancer depends upon his chronological age, his emotional maturity, his general patterns of behavior, his typical reactions to stress and crisis, his family constellation and relationships, his economic situation, and his relationships and activities as a member of society. Interwoven into this composite pattern is his knowledge of cancer in general and of his own illness and its probable outcome, and his previous experiences with medical care. The attitudes and reactions of the family will be determined by some of these same psychosocial factors as well as by feelings about the specific member who has cancer.

The patient may have suspected cancer because of his symptoms and perhaps because other members of his family had it. Or he may have had no suspicion that his symptoms were related to cancer. In either instance, he will probably undergo shock when he guesses or receives the diagnosis. If the information is given by an understanding physician, he will be permitted to react to the shock with tears, disbelief, expression of hopelessness, with anger, or other typical reactions to crisis. Then, with the relief of expressed emotion, he may be able immediately to mobilize his personal resources to proceed with the recommended medical regimen. If so, he will have

incorporated his illness into his life in its proper place—to have cancer, not let cancer have him.

Reactions Vary

Everyone is not able to make so rapid a response. Some react with self-blame for the fear or reticence which kept them from seeking medical care early. Some, mystically, seek some wrong which they committed to deserve such punishment. Some react with hostility toward their families because other members had the disease. Some project blame onto physicians who failed to make an accurate diagnosis or did not tell them the diagnosis. Others are furious at a society in which they are unable to purchase adequate medical care or which requires the expenditure of large sums of money without providing cure. Frequently, sufficient relief and better perspective comes from talking out these feelings with a professionally qualified person if family or friends are too close to be of help or the patient does not want to disturb them. Periodic opportunity to get this kind of relief from tension has helped many patients find the positives in their situations, focus on them, and carry on self-reliantly.

The Adjustment

Patients with terminal cancer learn to live with the knowledge of death in the foreseeable future. A comparative few are hopeless—living constantly with a specter while they wait for actual death. Some sink into depression, some into martyrdom. Some become controlling and dominating, and some drive themselves relentlessly in search of a cure. Others talk

Miss Thomas, lecturer in medical social work at the Graduate School of Social Work, University of Utah (on leave from the University of California Hospital), presented this paper at the American Cancer Society's program, National Conference of Social Work, Chicago, May 27, 1952.

frankly of the reality of death as part of life in its proper perspective. To some it is an anticipated release from suffering for themselves and their families. Many find diversion and a sense of satisfaction in taking practical steps to arrange their affairs and plan for and with their families. Most families need encouragement to let the patient share this responsibility rather than overprotect him.

Sometimes physicians also need such encouragement. One patient was made much more comfortable in his last hospitalization when, following the medical social worker's explanation of his need and desire for specific information, his physician was frank with him regarding his life expectancy, gave him a pass for several days so that he might arrange his business affairs to provide for his wife's future and his son's completion of college, and attend his daughter's wedding.

Other patients have wanted to be part of the planning and process of obtaining financial assistance or other social agency services. Young mothers have had release from much anxiety through persuasion of their families to let them participate in plans for the children so that the family might be kept intact after the mother's death. The families, too, have learned to live with, but uncontrolled by, the knowledge of death.

Religious faith has sustained both patients and families. Early contact with the proper clergyman is important to prevent the frightening feeling of "last rites" upon his appearance. One entire medical team, and particularly the medical social worker, worked long and hard to help one of the most restless patients find the religious faith and particular church in which she could have not only comfort, but also an opportunity to serve—an intercultural, interracial organization. Some patients develop the most positive philosophy of life they have known by filling each day full of as interesting living as their strength will permit. Some become altruistic and want their experiences, and even their bodies, to increase the knowledge of cancer for the benefit of others.

The attitudes of the patients and families are frequently determined by, or determine, the kind of care which is available and acceptable to them. It has become almost a truism in social

work that, except for the comparatively few really destructive situations, people are most satisfied in their own homes. This has been found to be true of patients with cancer. Frequently, adjustments need to be made to facilitate care at home. Anxieties need to be relieved through explanations of the illness and care of the patient, through financial supplementation, through housekeeping assistance, through furnishing of supplies, and through periodic relief for the member caring for the patient. Great security comes from the knowledge of the certainty of visits by physicians and nurses and of the availability of hospitalization when it becomes essential.

Care at Home

Mothers have been maintained at home until within days or hours of their deaths by such services and the emotional support given them and their husbands and children by social workers and others. While the visiting nurse was caring for one mother, the social worker helped her son play and talk out his fears at the sandpile in the back yard. She explained about the visiting housekeeper and the plans for his mother's care and she gave him her business and home telephone numbers so that he might have the neighbor call when his mother became worse and his father could not be reached.

But what of lone patients who do not have families to care for them? They, too, want to maintain their usual living habits. Frequently, it is the physician who is most apprehensive about letting them stay home and who needs assurance from the social worker that adequate arrangements have been made for observation and care.

One patient maintained herself and her apartment through the purchase of a refrigerator and arrangements for weekly shopping by a neighbor. Another patient was able to stay in his hotel room because the hotel clerk, assured that cancer is not "contagious," offered to "keep an eye on him" and keep in touch with the clinic. A third not only maintained himself in a hotel room following a tracheotomy (he did not have a hemorrhage) but went back to his job as a cook in a tuberculosis sanatorium, where he would not be seen by too many prying eyes nor have to talk much.

Final hospitalization may be distasteful because it so frequently means care in county hospitals which, even though adequate medical and nursing care may be available, are overcrowded and can give little personal attention. Patients and families have many times been helped to accept such hospitalization for the value of medical and nursing care, when they cannot afford expensive nursing home care. The personal attention can be supplemented through visits and services of family and friends.

The attitudes of patients with terminal cancer and of their families are as varied as the people who have them. On the whole they are attitudes of great strength of people facing a difficult reality with their own and the resources put at their disposal by those who wish to share with them. Their positive philosophies of life have influenced those of us who know them toward more constructive attitudes of our own. The attitudes toward cancer of all of us will, in turn, condition the attitudes of other patients and families. They can, and should be, positive.

United Nations Day, October 24

The President of the United States has designated October 24, 1952—seventh anniversary of the coming into force of the charter—as United Nations Day. The formal proclamation notes that “the founding of the United Nations has given the people of the world an organization through which nations may resolve their differences without resort to war and has made possible greater international cooperation in the economic, political, and cultural fields.”

“Realization by citizens of other nations,” President Truman said, “that the overwhelming majority of Americans support the United Nations and its great purposes would help to speed the day when there will in fact be peace on earth, good will toward men.”

The Secretary-General of the United Nations, in a message, points out that “today it is only too clear that we are still far from achieving these ends. We live amid bitter ideological differences, massive conflicts of power, localized fighting, and the danger of a world war which may wipe out civilization.

“This is a situation which we must face squarely,” the Secretary-General emphasized, “but we must also note what we have attempted and achieved. . . . We see major failures and setbacks, but also persistent effort. We see good beginnings and some achievement in almost every field.

“However, these are only the first steps towards goals never before reached. Faith and work for many years is needed to eradicate the age-old evils of war, poverty, and inequality. This perspective we must always bear in mind.”

Sanitation

aboard American Flag Vessels

S.S. United States

By EDMUND C. GARTHE, C.E., M.P.H., and HOWARD W. CHAPMAN, B.S.C.E., M.P.H.

When the S.S. *United States* sailed on her maiden voyage a few weeks ago, three decades of maritime sanitary engineering experience in the Public Health Service went with her. This newest, largest, fastest, and costliest passenger ship ever built in this country was constructed in full compliance with every standard of vessel sanitation.

The 12-deck, 2,000-passenger liner is 990 feet long and grosses 53,000 tons. Her crew numbers 1,000. Built into her is the capacity to carry from 12,000 to 14,000 troops in the event of war. On her first trans-Atlantic round trip, she broke the existing speed record for both the

east and west crossings. From her red, white, and blue stacks down to her keel, she is a sleek, sturdy beauty, designed and built for comfort and safety as well as speed.

The Public Health Service became involved in the protection of American citizens aboard interstate carriers because State and local health departments were under obvious handicaps in attempting to enforce the most basic sanitary measures. Since then, the sanitary engineers of the Service have built up a fund of knowledge and have developed many features and techniques of sanitary construction and maintenance. These began to flow into the *United States* while her very first plans were still on the architects' drawing boards.

Except for the vast size of this liner, and the glamor associated with her, she represents to the Public Health Service simply one more conveyance built with due regard to health and sanitation. When the trial voyage was completed, a Public Health Service vessel inspector presented the Certificate of Sanitary Construction—the same certificate awarded to any ship built in accordance with established standards.

Mr. Garthe, chief of the interstate carrier branch of the Division of Sanitation, Public Health Service, participated in the meeting of the International Labor Organization's Committee of Experts on Accommodation and Welfare of Migrants on Board Ship, Geneva, September 22-27, 1952. Mr. Chapman is assistant chief of the branch.

It seems to be axiomatic that while accidents and epidemics appear to be dramatic, safety and health do not. That Certificate of Sanitary Construction may never be seen by any of the thousands of passengers the *United States* will carry. Yet, it will be of great personal importance to them. Accompanied by correct operation of facilities, it is their assurance of safe drinking water and sanitary food service; their protection against the diseases borne by rats and other vermin; their guardian against infection from practically any foreseeable environmental source.

Early Sea-going Sanitation

The roots of the Public Health Service vessel-sanitation program date back to the later years of the 19th century. It has been marked by continued cooperation between the Service, the Maritime Administration, and the shipbuilders, naval architects, and ship operators. Objections to high standards of construction and operation were rare, with one of the results being the acceptance of these practices by maritime interests throughout the country.

It was not until 1917, however, when the Interstate Sanitary Districts were established by the Service, that the development of sanitary standards for interstate carriers, and the supervision of their operations affecting public health, became a regular, working function of the Service.

In those earlier days, water supply was practically the only sanitation factor given serious consideration aboard vessels, and for practical purposes only river and Great Lakes vessels were inspected. Efforts were made within the foreign quarantine responsibilities of the Service to improve sanitary conditions aboard ships flying the Stars and Stripes in foreign commerce. An all-inclusive sanitation program began to emerge in 1944.

The Holzendorf Concept

The earlier emphasis in sanitation on ships arriving from overseas ports was on rat control, since the chief purpose of quarantine was to prevent entrance of certain diseases—principally plague—into this country. The fumiga-

tion measures used in efforts to eliminate rats aboard ships in the early days were rather costly and time-consuming, and, therefore, understandably unpopular with the operators. In 1920, Public Health Service Pharmacist Benjamin E. Holzendorf conceived, and began working on, the idea of ratproofing ships while they were under construction. He reasoned that it should be possible to build a ship in such a manner that rats would have few places to harbor and nest. This would keep the rat population so limited that fumigation would not be required. Holzendorf was able to demonstrate his theory, and since then through the course of the years definite specifications on the ratproof construction of ships have been developed and have become widely accepted by the industry. The ratproof construction of ships is now an integral part of the over-all sanitation program.

The Interstate Carrier Branch

The purpose of the vessel sanitation program, of course, is to minimize the transmission of disease aboard vessels and to promote the health of crew and passengers. These floating communities must provide all the health facilities which landbound communities in this country are expected to supply—safe water and food, sewage disposal and sanitary facilities. It is difficult enough to provide such facilities and services ashore; to provide them aboard a ship involves problems vastly more complex and difficult. However, very few epidemics traceable to ships have been reported within recent years, and most of these have been traced chiefly to vegetables and other uncooked foods which have been loaded in foreign ports.

The interstate carrier branch of the Division of Sanitation carries out virtually all of the Service's carrier-sanitation responsibilities, including those on railroads, airlines, and buses, as well as ships. Most of the actual inspection work is carried out through regional offices, with the central office establishing policy, preparing and revising standards, and providing technical assistance.

As early as 1930, the Maritime Commission (now Maritime Administration) established a

still-existing policy that all ships constructed under its jurisdiction and subsidized by it must be constructed in accordance with Public Health Service sanitation standards. Virtually all American flagships today are built and operated in compliance with them.

Vessels Under Construction

A vessel which is constructed or reconstructed in accordance with Public Health Service vessel sanitation standards is issued a Certificate of Sanitary Construction (1). When it is established that a vessel is to be constructed in accordance with these standards, all pertinent plans and specifications are submitted to the appropriate regional office for review and approval prior to construction, usually in sets over a period of time as the design work progresses. During actual construction, the Service's vessel inspectors in the region follow the work closely to be sure that the standards are being followed, and to advise on items which may not have been shown in the plans. This procedure assures that defects will not be built into the ship which will require costly changes later.

Features of public health importance are the potable-water system, the wash-water system, drainage and waste disposal, food-sanitation facilities, ratproofing, and special facilities such as swimming pools.

Potable Water

Water of drinking quality can be obtained from almost any port in the United States. However, if the water should not be of drinking quality, or if it should be stored improperly aboard the vessel, it must be adequately treated before being used. The minimum treatment, if any is required, varies with the original quality of the water and the method of storing, as indicated below:

<i>Source of Water</i>	<i>Treatment</i>
Safe shore water, delivered to the ship and stored satisfactorily-----	None.
Overboard water from uncontaminated areas in Great Lakes-----	Chlorination.
Safe shore water stored improperly aboard the vessel-----	Chlorination.
Polluted overboard river water-----	Distillation.

Vessels in foreign trade usually do not have sufficient storage capacities to provide needed fresh water (including potable water) for the entire trip. (It has been estimated that 0.7 gallon of drinking water is required per day for each person aboard a vessel.) In these cases, it is necessary to manufacture fresh water from overboard salt water. For this purpose, either of two types of distillation processes may be used: high-pressure evaporation (atmospheric pressure or above), or low-pressure evaporation (low-pressure or partial-vacuum distillation). Most ocean-going vessels utilize the low-pressure method since it is much more efficient and produces fresh water at lower cost.

To determine the potability of water produced from salt water by low-pressure distilling plants operated at temperatures below 165° F., a joint study was made in 1947 by the Public Health Service, Maritime Commission, and the shipbuilding division of the Bethlehem Steel Company. This study showed that water so produced with a salinity of 1/4-grain per gallon or less is potable. Accordingly, the Service ruled that such units must be equipped with a salinity indicator and an automatic flow-diversion valve after the final condensate cooler, to divert to waste any water produced with a salinity greater than 1/4-grain per gallon.

In order that stored water may be adequately protected against contamination, it is desirable that the tanks do not have common walls with either the skin of the ship or any tank which carries a liquid of lower quality than drinking water, since any leak in the tank wall may go undetected and contaminate the potable water. Also, all appurtenances, such as manholes, vents, overflows, depth indicators, and drains, must be designed to prevent contamination from being introduced into the tank. For example, before the development of precise standards covering construction of water systems, the usual method of determining the quantity of drinking water in a tank was to insert a rod through the manhole or vent—an excellent means of contaminating the water. The present standards permit the use of pet cocks placed at intervals in the side of the tank, a glass gauge in the side of the tank, or other type of indicator which is entirely enclosed. No drain lines are

⑧

⑨

allowed to pass through the tank, since unobserved leaks may occur. Toilets are not permitted to be placed immediately above the tank manhole.

From storage tank to ultimate outlet, the water system should be entirely self-enclosed. Cross connections to other water systems of lower quality are not permitted, and plumbing defects, such as submerged inlets or direct connections to equipment, are allowed only if approved vacuum breakers are used. To assist in preventing a line leading from a nonpotable-water system from tying into the potable-water system, the standards require that all potable-water lines be definitely identified.

Before a newly constructed or newly repaired ship goes into service, the entire potable-water system must be adequately cleaned and sterilized.

Wash Water

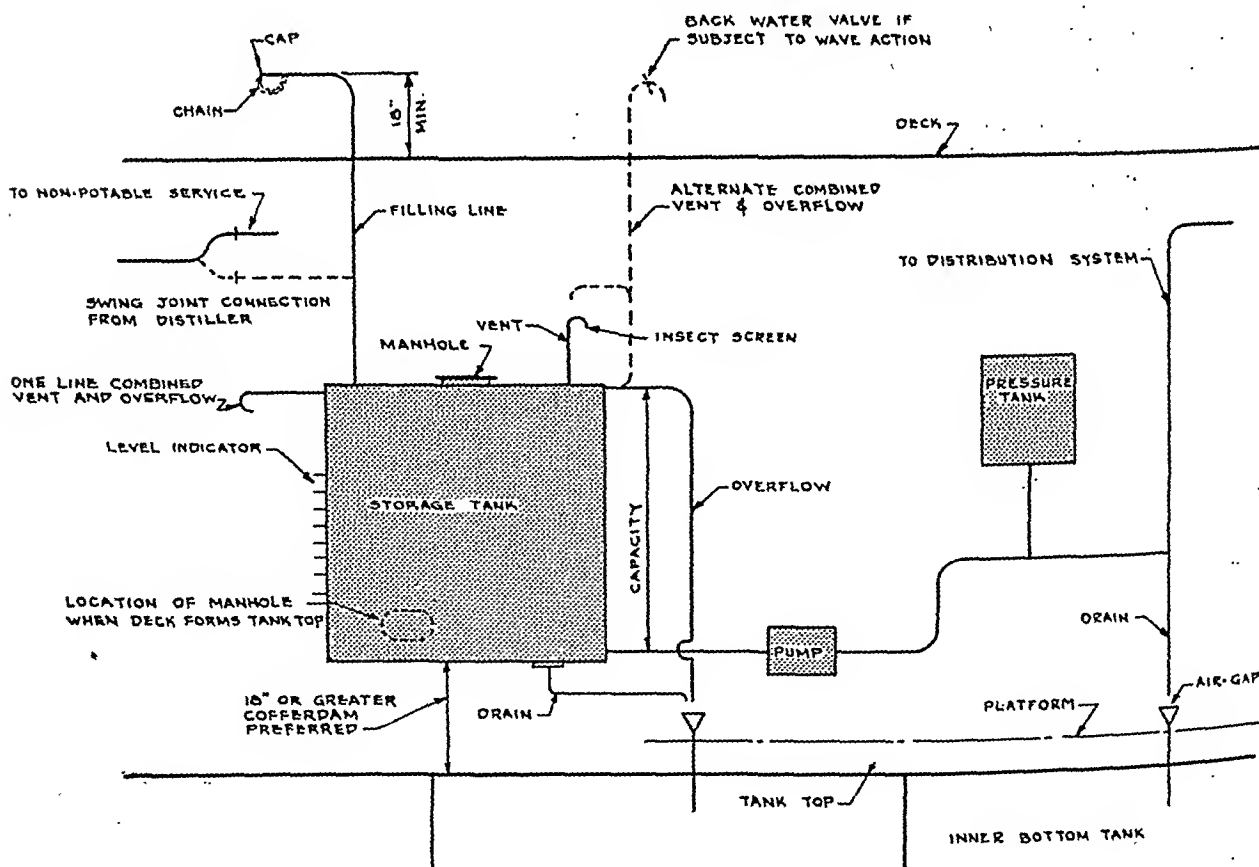

The Service recommends to shipbuilders and shipowners that, whenever possible, fresh water

for all purposes—drinking, cooking, washing—be provided by a single water system. Most of the vessels built within the last few years have the single fresh-water system. Some vessels, however, do not have enough space to permit storage of all fresh water in detached tanks, and skin tanks must be used. All faucets in living spaces on a separate wash-water system must be clearly posted with signs reading, “Unfit for Drinking.”

Standards have been developed specifically to cover wash-water systems. In general, these standards are similar to the potable-water standards previously discussed, with the following exceptions:

1. Safe shore water may be stored in skin tanks.
2. Water from unpolluted areas in the Great Lakes need not be chlorinated.
3. Polluted overboard river water may be used, if treated by filtration and chlorination.

Figure 1. Typical independent water system.

Most of the large ocean-going passenger ships built in recent years have swimming pools which are of the flowing-through type, utilizing overboard salt water. In the design and construction of these pools, the standards of the American Public Health Association are used. Special consideration must be given to the quality of salt water taken aboard for use in the swimming pool. An independent water system for this purpose is preferred; however, with certain safeguards, water from the fire or sanitary system may be used.

Food Sanitation

In general, the standards set forth in the Ordinance and Code Regulating Eating and Drinking Establishments (2) govern food-service areas and equipment aboard vessels. When a ship is to be built in accordance with Public Health Service standards, detailed reviews are made of plans showing food spaces and equipment, including layout plans showing the arrangement of equipment and plumbing, bills of materials for food equipment, and specifications of materials covering deckheads and bulkheads. The obligation to approve or disapprove trade-marked equipment sometimes requires considerable time for investigation and study.

A food-service problem peculiar to seagoing vessels is the large amount of storage space which must be provided. A large proportion of the storage space must be refrigerated and with specific optimum temperatures provided for each type of food.

In general, vessels constructed in the last few years have up-to-date galley equipment and food-service equipment. This applies to small towboats and river boats as well as to ocean-going vessels. Most operators make every effort to provide their crews and passengers with the best in food and food service.

As compared with shore food-serving establishments, vessels have some unusual features which must be taken into consideration. For example, the general complexities of ship construction and the tight space limitations often make it necessary to pass soil and other waste lines through the deckheads of food spaces.

Special precautions must be taken to prevent leakage.

On the other hand, in one feature of galley sanitation at least, vessels have an advantage over the usual shore establishment: the matter of an adequate hot-water supply. Vessels generally have an abundant supply of steam or electrical power which can be used for water-heating purposes. The installation of booster heaters in hot-water lines to dishwashing machines, as well as of auxiliary heating units in sinks, is a well-established practice.

Drainage and Waste Disposal

The drainage of a ship poses significant sanitary problems. Two kinds of drainage are of primary concern to the Public Health Service—human and hospital liquid wastes, and drainage from decks, food spaces, and food equipment. Vessel drainage systems include the usual features of traps, cleanouts, and vents, which are well defined in plumbing codes.

The main objective is to keep the two types of drainage systems separate so that human sewage cannot contaminate food spaces and equipment or living spaces. When it is necessary to combine the two types of drainage for discharge overboard, specific safeguards have been developed to prevent backflow into food spaces and equipment. When there is any pos-

Figure 2. Broken drainage system—overboard-water-operated ejector.

sibility of such backflow, the drain must pass through an air gap (fig. 2).

Ratproof Construction

Ratproofing is strongly recommended for all American ships engaged in foreign trade. To the shipowner, one of the virtues of ratproofing is that it facilitates passage of a ship through quarantine by eliminating the need for fumigation or other rodent-control activities which might delay the ship.

Essentially, ratproofing a ship means designing and building it in such a manner as to eliminate or make inaccessible to rats any spaces affording harborage where they may nest and breed or have access to food.

Over a period of years, detailed specifications have been developed on how to ratproof virtually every space in the ship, including cargo holds, refrigerated spaces, and food areas. In general, ratproofing involves either the use of rat-resistant material to prevent the passage of rats, or the utilization of "open-type" construction. In evaluating materials as to their rat-resistant characteristics, special consideration must be given to their ability to withstand shock in certain areas, such as cargo holds.

Before certifying that a ship is ratproof, the vessel inspector examines every part of the ship. Openings greater than one-half inch, leading into uninspectable spaces or food spaces, must be closed. Collars of sheet metal must be installed around penetrating fixtures, regardless of size or location. Edges may be required to be flashed to prevent gnawing. Uninspectable areas, such as those above wireways and ducts, may have to be closed. In short, as an inspector once said, one of his most important qualifications is his ability to think like a rat first—and then like a ratproofeer.

Vessels in Operation

The program as it relates to vessels in operation is concerned with the routine maintenance of high sanitation standards. A ship may contain the best equipment to provide a safe and sanitary environment for its passengers and crew, but if the members of the crew are either

Figure 3. Number of companies having certain average vessel sanitation ratings.

uninformed or uninterested in correct sanitation procedures, the effort and expense will be in vain.

Through a program of inspection and education on vessels in both interstate and foreign trade, efforts are made constantly to improve sanitary practices. Comprehensive inspections are made at 6-month intervals by regional vessel-sanitation inspectors, covering every phase of environmental sanitation. The standards set forth in the "Handbook on Sanitation of Vessels in Operation" (3) are used as guides, and the inspectors use a formal inspection report form. Numerical values are assigned to the various items on the inspection form, from which the vessel's sanitary rating is determined. Vessels which obtain a rating of not less than 95 percent on sanitation items and not less than 90 percent on ratproof construction are awarded the Public Health Service Certificate of Sanitation.

The Certificate of Sanitation (which is issued, also, to railroad dining cars) is a comparatively recent development in the carrier-sanitation program of the Public Health Service. While still virtually unknown to the fare-paying public, its presence on board a vessel is becoming more and more a matter of great importance to the merchant mariners to whom their ship is, for considerable periods of time, both their home and home town.

Every 6-month period finds more and more American ships meeting the certificate standards of the Public Health Service. Over 2,700 vessels of all classes, operated by approximately

270 companies, come under the vessel-sanitation program. The 1951 report shows that the average rating was 87.9 percent (fig. 3).

Another element of the program concerns sources of safe water, milk, and food for operating vessels. In cooperation with State health departments, the Public Health Service inspects and classifies all water and milk sources reported in use by vessel-operating companies throughout the United States. Periodically, it publishes lists of sources, classified as "approved," "provisionally approved," or "prohibited."

Because vessel watering points pose a special problem to engineers and inspectors, the Service has prepared special standards, which are to be published soon. The standards for certifying milk sources are those developed by the Public Health Service over the past 30 years, a new edition of which is in press (4).

Training Vocational Rehabilitation Counselors

A national program to help emotionally disturbed persons get and hold jobs that will support them was started in July when the first of a series of short courses for training counselors in vocational rehabilitation was held at San Jose State College, San Jose, Calif. The 2-week course at San Jose was attended by 20 counselors from 12 State vocational rehabilitation agencies in Arizona, California, Colorado, Idaho, Louisiana, Montana, New Mexico, Oregon, Texas, Utah, Washington, and Wyoming.

A second course, similar to the one at San Jose, will start at Columbia University, New York City, on January 12, 1953, and will run for 2 weeks also. Another course will be held later at Menninger Foundation, Topeka, Kans.

The San Jose course covered five training objectives: (1) development of leadership for programs of vocational rehabilitation; (2) practice in skills and techniques needed in rehabilitating persons with neuropsychiatric disabilities; (3) appreciation of community resources and consultative services for effecting rehabilitation and placement; (4) provision of information about human behavior and personality disorders; and (5) development of personality adjustment patterns to bring about favorable attitudes toward counseling, training, and placement of the mentally ill.

The program is under the joint sponsorship of two units of the Federal Security Agency: the Office of Vocational Rehabilitation and the National Institute of Mental Health of the Public Health Service.

International Sanitary Regulations

By KNUD STOWMAN, Ph.D.

This year, on October 1, the quarantine provisions in the existing international sanitary conventions and agreements, 13 in number, dating from 1903 to 1946, were replaced by a single text—the International Sanitary Regulations of the World Health Organization. This means that uniform rules will give a maximum of protection against the transmission of pestilential diseases with a minimum of interference with travel and trade. It also means that travelers on an international voyage will no longer be exposed to arbitrary action on the part of quarantine services at the place of arrival as has hitherto been the case in many countries.

Living in the Past

The lack of universal quarantine rules has been particularly grave in the field of air navigation, which is precisely where they are most needed. Only 29 countries ever ratified the International Sanitary Convention for Aerial Navigation of 1944, modifying the one of 1933. Fourteen countries, moreover, still adhered to the 1933 convention as originally written. Ten of these 43 countries, among them the United States, had made more or less sweeping reservations, reserving their freedom of action. Some 40 countries, many of them important in air traffic, never became a party to any sanitary convention and could therefore deal with planes and passengers as they pleased.

In regard to maritime navigation, 29 countries had ratified the 1944 convention modifying the 1926 convention. Twenty of the coun-

tries that ratified the 1926 convention did not ratify the 1944 one. Ten countries still went by the 1912 convention. The remaining countries had never become a party to a convention.

In other words, there was a lag of nearly half a century in the conceptions of many countries as to how to deal with matters concerned with foreign quarantine. Turning back the clock merely a quarter of a century places us in the days when there were neither antibiotics nor cheap, powerful insecticides. There was no yellow fever vaccine then, and Soper had not yet discovered jungle yellow fever. Plague-infected vessels were commonplace. Cholera, typhus, and smallpox had recently made dramatic raids into Europe. In short, only yesterday half of the official world was acting as if it were living among the shadows of a remote past, undisturbed by the droning of airliners in the skies, unaware of the magic of modern preventive medicine, afraid of ghosts long laid.

The need for uniform quarantine rules had been recognized for a century. The first international sanitary conference met in Paris in 1851. Subsequent conferences were held in capitals ranging geographically from Washington in the West to Constantinople in the East. Because of lack of knowledge regarding the transmission of epidemic disease, the conferences accomplished for the ensuing 50 years little more than keeping the problem alive in the minds of the government departments concerned.

The seaborne plague pandemic, which reached all continents except Australia around the turn of the century, greatly strengthened interest in standardized quarantine measures. The first international sanitary convention was concluded in 1903 and brought up to date in 1912. The Pan American Sanitary Bureau was founded in 1902 and the International Office of Public Health in Paris, in 1907. Reg-

Dr. Stowman, of the Division of International Health, Public Health Service, was a U. S. delegate to the Special Committee of the World Health Organization on the International Sanitary Regulations.

ulation of quarantine measures, originally agreed upon only for plague and cholera, were gradually extended to yellow fever, smallpox, and typhus. The most important international quarantine conventions were those of 1926 for shipping, of 1933 for air navigation, both revised in 1944, and the Pan American Sanitary Code of 1924.

The procedure of international conventions was slow and cumbersome. Ratifications came in tardily, if at all. The Pan American Sanitary Code was the only instrument ratified by all the countries concerned. The means of epidemic control progressed by leaps and bounds, and the pattern of international travel changed almost overnight, hopelessly outmoding the conventions before they were ever ratified. It became evident that new ways had to be found if order was to prevail in this important field of foreign relations.

International Health Legislation

With the entry into force of the constitution of the World Health Organization, a solution of international quarantine problems became possible. Article 21 (a) of the constitution provides that the World Health Assembly shall have authority to adopt regulations concerning sanitary and quarantine requirements and other procedures designed to prevent the international spread of disease. According to article 22, such regulations shall come into force for all member states unless they notify the Director General of WHO of rejection or reservations within the period stated in the regulations. In the United States, the constitution of the World Health Organization was approved by Joint Resolution of the House and the Senate, and the bill was signed by the President on June 14, 1948.

An Expert Committee on International Epidemiology and Quarantine was set up by the World Health Organization, and the opinions of numerous experts on related matters were obtained. In 1949 WHO international regulations successfully met their first test in one of the less controversial fields—nomenclature of diseases and causes of death. In 1950 the expert committee finished its first draft of the quarantine regulations and it was sent to the governments for their comment.

In the United States, the draft was carefully reviewed, and many recommendations for changes were made by an ad hoc committee set up by the Department of State. The Public Health Service, the General Counsel of the Federal Security Agency, the Army, Navy, and Air Forces, the Departments of Commerce and Justice, the offices of the Department of State concerned, and shipping and air transport interests were represented on this committee. A new draft, taking into account the recommendations of governments, was prepared by the WHO Expert Committee on Quarantine. This draft served as a basis for the deliberations of the Special Committee on International Sanitary Regulations which met in Geneva in April 1951 with all member states invited.

Forty nations were represented at the meeting of the special committee, which lasted 5 weeks. The committee was reconstituted by the Fourth World Health Assembly immediately after the meeting. Sixty-four nations participated in the final deliberations. The delegates, who were speaking officially for their governments, included many prominent experts in epidemiology, quarantine procedure, and international law.

The delegation of the United States took an active part in the work of the committee. The interests of the United States in foreign travel and trade by air and by sea have increased enormously in recent years, while the high state of our public and personal sanitation has made us practically impervious to outbreaks of such pestilential diseases as cholera and louse-borne typhus. While the United States was formerly among the highly "protectionist" countries in regard to quarantine measures, there is now reason to revise our stand. However, the country is still exposed to smallpox and so is anxious to have adequate vaccination requirements.

European countries with a high state of sanitation tended to be "liberal" while the more vulnerable countries of South Asia and the Near East tended to be "protectionists," but positions fluctuated with the nature of the problems. A firm intent to keep the discussions on a scientific level was nevertheless in evidence. The position of the delegation of the United States may be described as "middle of the road." We were primarily concerned with bringing the nu-

merous countries hitherto fairly free to exercise arbitrary action under an up-to-date system of rules, and providing an efficient administration of this system and a machinery for keeping it up to date. We were thus particularly interested in having the various provisions adopted by large majorities so that subsequent reservations or rejections would be reduced to a minimum.

The Epidemiological Situation

The world situation in regard to pestilential disease presented to the special committee was very different from the one confronting the groups who drafted the 1926 and 1933 conventions. New powerful insecticides, such as DDT, have greatly facilitated the control of plague, typhus, and urban yellow fever. A most reliable vaccine against yellow fever is now widely used. New methods of treatment make plague, typhus, and cholera less deadly than formerly. In general, defenses against disease are much better now than then. However, transoceanic air travel has brought us much closer to the great endemic foci of pestilential diseases.

The incidence of several of the quarantinable diseases has diminished greatly, largely because of the more effective means of control. Yellow fever has long been confined to jungle areas in Africa, South America, and Central America. Plague has become almost entirely a rural problem. Apart from the plague centers in Communist China and other Communist areas, where no information is available, plague in Asia is now limited to restricted areas of Java, Vietnam, Cambodia, Burma, parts of India, and a few remote spots in the mountains of Iran and Arabia. There is an old plague center around the Rift Valley in central Africa and another in Madagascar. Various rural areas in Argentina, Peru, Ecuador, Venezuela, and northeastern Brazil still produce a few plague cases. Sylvatic plague exists in South Africa and in the western United States. Only five seaports, all in South Asia, have been plague-infected within the last few years. There have been only two known plague-infected ships in the world during the last 5 years. Apart from a few sporadic cases, cholera has been confined during the last 3 years to the countries around the Bay of Ben-

gal—India, East Pakistan, and Burma. Cholera is endemic in certain areas of southern China, but no recent information is available.

Smallpox alone among the quarantinable diseases has a world-wide distribution and is of frequent occurrence in many seaports and airport cities. The smallpox-free area of the world consists only of Alaska, Canada, the West Indies, Greenland, Iceland, the Scandinavian countries, Australia, New Zealand, the Philippines, and the Pacific Islands. In the United States, there are now only a few sporadic cases of the mild type in some midwestern States. In western Europe, smallpox is no longer endemic except in parts of Portugal, but minor outbreaks traceable to imported infection still occur from time to time. Most of Asia and Africa and parts of South America are still heavily infected with smallpox, and the prevention of its international transmission remains a major problem.

It is evident from this summary that a large part of the world traffic is no longer exposed to infection by plague, cholera, or yellow fever. Another large sector may be exposed only occasionally to smallpox. It should be possible, therefore, to avoid delays on account of quarantine measures in regard to a very substantial part of international travel.

Epidemiological Information Network

In order to apply quarantine measures intelligently, it is indispensable that information on the incidence of the quarantinable diseases, and especially of new outbreaks, should be available without delay. The epidemiological information required under the old conventions was clearly insufficient. Smallpox, for example, was not required to be reported unless there was an epidemic, and the definition of an epidemic was left to the discretion of local health officers. The United States, consequently, when ratifying the 1926 and 1933 conventions, reserved the right to determine which localities were infected. However, if each country were to determine which parts of the world it wanted to consider infected, the road would be wide open to arbitrary action of various kinds.

The United States delegation, therefore, strongly advocated complete, regular, and im-

mediate notification of any occurrence of plague, cholera, yellow fever, and smallpox, as well as of plague infection among rats. The proposals of the American delegation were on the whole accepted. Under the new regulations we shall have a world-wide epidemiological information system modeled on that developed since 1925 by the League of Nations, now the World Health Organization, epidemiological station at Singapore. The Singapore station has probably contributed more than any other single factor to the disappearance of plague and cholera from all but a few ports of South Asia. Other relevant information, notably regarding the state and workings of the quarantine services, is also required under the new regulations. The development of the epidemiological information network has reached a point where it is felt that it can meet the requirements of the new system.

Vaccination and Insect Control

Another important point carried by the American delegation, although against considerable opposition, was the right of a country to require a valid smallpox vaccination certificate of any traveler arriving from abroad. Hitherto, we have exercised this right on the basis of our reservation to the 1926 and 1933 conventions, but we would not have been in a position to have a similar reservation accepted for the regulations. At present, we waive the requirements for arrivals from Canada and various other nearby areas. However, it is our opinion that, in view of the ubiquitousness of smallpox and its long incubation period, there can be no other guarantee against international transmission than adequate vaccination of all travelers who may possibly have been exposed to infection.

Safeguards against the transmission of yellow fever are based on vaccination of travelers proceeding from infected to receptive areas and on disinsectization of planes. Yellow fever vaccination is considered to give full protection against the disease for at least 6 years.

As heretofore, measures against international transmission of plague are directed against the presence of rats on ships and in ports. Half-yearly examination of ships for rats remains

compulsory, but as a large majority of ocean-going ships are now ratproof, the number of deratting operations is declining rapidly. Deratting and disinsectization of other means of transportation may be undertaken if necessary. Except in the case of pulmonary plague, measures against plague are now directed against rodents and their ectoparasites rather than against people. Anti plague vaccination cannot be required as a condition of entry into a country.

Vaccination is an important element in the prevention of cholera. Surveillance for not more than 5 days, reckoned from the date of departure from an infected local area or debarkation from an infected ship, will be substituted for isolation if the passenger is properly vaccinated. Unfortunately, the immunity conferred by vaccination is of short duration, and the vaccination must be repeated every 6 months. The regulations prohibit rectal swabbing unless by consent of the passenger, and stool examinations may be required only if a passenger coming from an infected local area within the incubation period shows symptoms of cholera.

Louse-borne typhus and relapsing fever are now prevented so readily that special measures are not compulsory. Regulations have been kept on the books for use in exceptional cases of epidemics brought about by war or other disturbed conditions. Vaccination against typhus shall not be required as a condition of admission to an area.

Measures to facilitate quarantine procedures, such as the granting of radio pratique to ships and aircraft, are encouraged.

The only international sanitary documents which may be required are certificates of vaccination against smallpox (validity 3 years), yellow fever (validity 6 years), and cholera (validity 6 months), Deratting Certificate and Deratting Exemption Certificate, the Maritime Declaration of Health, and the health part of the Aircraft General Declaration. Charges for medical examinations or vaccinations on arrival are prohibited.

Unanimity and Few Reservations

The International Sanitary Regulations were adopted unanimously on May 25, 1951, by the

64 member states present at the Fourth World Health Assembly. In voting the regulations the assembly passed several resolutions dealing with their administration and with allied problems. The duty of governments to maintain the highest sanitary standards, notably in their ports and airports, including elimination of rodents and mosquito vectors, was stressed.

After careful examination by all Government departments and agencies interested and the industries concerned, the United States decided to make no reservations. Leaving out of consideration the 10 member states of the Communist bloc which have announced their withdrawal from WHO and therefore cannot be counted upon to apply the regulations, there remain 69 member states and associate members. Forty-eight of these governments, including countries with large international traffic, such as the United Kingdom, France, Italy, Spain, Brazil, Mexico, Japan, and Indonesia, made no reservation. This is a proof of the soundness of the procedure and a high compliment to the work of the special committee of the World Health Assembly.

Article 107 of the regulations provides that reservations, in order to become effective, must be accepted by the World Health Assembly. Preliminary examinations of the reservations were made by a small ad hoc committee. The Fifth World Health Assembly set up a working group on which all member states were represented. An important work of reconciliation between conflicting interests, in which the delegate of the United States participated actively, was performed in this working group. There are, of course, situations which merit special consideration. The regulations were not written to prevent any country from taking obviously necessary measures. Cholera-free Ceylon, for example, is next door to the endemic cholera foci of Madras Presidency. India, *Aedes aegypti* infested and with a huge monkey population, lives in deadly fear of the introduction of yellow fever. The Mecca pilgrimage holds dangerous possibilities. Some countries do not yet have the equipment required by the regulations. These and other justifiable needs were met without endangering the organic structure of the regulations, and almost everyone was satisfied.

Reservations from five democratic European countries related merely to parliamentary approval. Several reservations referred to matters of only slight importance and others were dropped. Satisfactory compromises were made on most points with Burma, India, Ceylon, Pakistan, Saudi Arabia, Egypt, and the Union of South Africa. The report of the working group was adopted by the assembly with 56 affirmative votes, 1 against, and 1 abstention. Practically all the active member states of the World Health Organization are parties to the regulations. In countries that do not adhere to the regulations the old conventions will remain in force.

It remains for the Sixth World Health Assembly to deal with reservations made on behalf of certain overseas possessions which may be made under article 106.2 up to December 11, 1952.

Administration of the Regulations

The Director General of the World Health Organization is charged with the international coordination of the regulations. He will have at his side a Committee on International Sanitary Regulations composed of experts in epidemiology and epidemiological information, port and airport sanitation, quarantine procedure, international law, shipping, and aviation. This committee will hold its first meeting sometime in 1953. It will review the workings of the regulations on the basis of an annual report by the Director General and make recommendations thereon, prepare additional regulations, when necessary, on diseases not covered by the regulations, make recommendations on practices and procedures, and assist the Director General, when necessary, in the settling of disputes.

An orderly and flexible procedure has thus been devised to adjust quarantine measures to changing requirements. The public is being protected against pestilential diseases as well as against undue interference with liberty of travel. Order has been brought out of confusion, good will between nations has been enhanced, and international legislation has been enacted by means of suitable machinery and democratic procedure.

Public Health in Veterinary Medicine

Topics of public health importance were presented frequently throughout the program of the eighty-ninth annual meeting of the American Veterinary Medical Association, Atlantic City, June 23-26, 1952. The program reflected the increasing importance of the control of diseases of animals as they affect the health of man. Public Health Reports briefs several of the papers which had more than usual public health significance. This briefing was made possible by the cooperation of Dr. J. G. Hardenburg, executive secretary of the American Veterinary Medical Association, and with the assistance of the authors—upon whose authority the material is presented.

Leptospirosis In Farm Animals

Leptospirosis, an infectious and contagious disease, may affect many species of domestic animals. First recognized in cattle in this country in 1944, evidence indicates that it has occurred endemically in Pennsylvania since 1945. Isolation of *Leptospira* in an outbreak of disease in swine was reported in 1952, and signs of the disease have also been observed in horses.

Symptoms and Signs

In bovine leptospirosis, fever, marked and sudden reduction in milk flow, and changes in the udder and in the quality of milk are noticeable symptoms. In some cases, the fever may be of short duration; in others, persistent. The udder is limp and empty and shows no inflammatory changes, distinguishing it from mastitis. The milk produced is thick, viscid, and yellowish. In mild cases, fever and sudden drop in

milk flow for a day or two may be the only detectable evidence of the disease.

In severe cases, pink milk, purple or portwine colored urine, and jaundice appear about the third to fifth day. The pink milk and purple urine denote the presence of hemoglobin, which is excreted as a result of excessive hemolysis. The purple urine helps differentiate leptospirosis from pyelonephritis, in which the urine is reddish from the presence of free blood. Anemia, which results from the breakdown of the red blood cells, aggravates the labored respiration and weakness already produced by the infection. Leptospiral organisms may be found in the urine about the time jaundice appears, if not earlier.

Occasionally, exceptionally severe cases of leptospirosis in cattle are fatal within 2 or 3

By W. E. LaGrange, D.V.M., assistant professor of veterinary medicine, School of Veterinary Medicine, University of Pennsylvania, Philadelphia; J. V. McCahon, D.V.M., general practitioner, Downingtown, Pa.; and R. B. Little, D.V.M., Rockefeller Institute for Medical Research, Princeton, N. J.

days, hemoglobinuria and jaundice not appearing at all or only terminally. In the average outbreak, however, the course of the disease extends from 3 to 10 days.

Diagnosis

In outbreaks of leptospirosis involving several cattle, evaluation of the history and symptoms should lead to a diagnosis. Diagnosis may be confirmed by recovery of the organism from the urine; inoculation of laboratory animals or cattle with urine, milk, or blood from clinical cases; or serologic tests after the outbreak has subsided.

Autopsy

In fatal cases, the tissues are icteric, and petechiae are commonly found on the pericardium and often on the liver. In some instances the liver shows centrilobular necrosis. The surface of the kidney should be studied for the presence of small, darkly pigmented spots, although small white spots diffused over the surface of the kidneys have been found in experimentally infected calves. The kidney tubules are usually the site of injury. They may be blocked by protein precipitates.

Treatment

In addition to general nursing care, adequate fluid should be provided to maintain good urine flow. The use of sulfonamides is very questionable, but penicillin medication appears to shorten the course of the disease. Aureomycin has been shown to have definite protective value for hamsters and dogs against some strains of *Leptospira*. At present, however, none of the antibiotics can be considered specific.

Definitely beneficial, in our opinion, are blood transfusions. If available, blood from recovered animals should be used since antibodies probably remain in the blood for some time after recovery. Blood from normal animals, however, will supply the needed red blood cells and plasma proteins.

Spread and Control

Evidence indicates that bovine leptospirosis spreads directly from animal to animal in the herd. When cattle urinate, the spray of drop-

lets may well carry the organism present in the urine of infected animals to susceptible animals. Any minute skin abrasion can afford a means of entry. Chronic carriers may be the means of spread from one herd to another.

Leptospirosis of domestic animals is not only a disease of economic importance in livestock, but should be regarded as of considerable significance as a public health problem. Infected animals should be quarantined and their milk sterilized before being discarded. Contamination of other animals and of equipment by urine should be avoided. Although the strains isolated from cattle in the United States have not yet been shown to be agents of human disease, types found in other countries have been clearly demonstrated to be pathogenic for man. These types may appear in this country at any time.

North American *Leptospirae*

The significance of leptospiral infections in man and domestic animals in North America is being increasingly recognized. What were but a few years ago considered exotic infections are today significant problems to human and animal health.

In the leptospiroses, as in other infectious diseases, laboratory diagnosis, prophylactic and control measures, and the development of immunizing and therapeutic agents are dependent upon the characteristics of the organisms themselves, their hosts and reservoirs, and the means of transmission of infection. The identification of infecting strains may, in addition to the clinical and epidemiological value, be of forensic importance in cases of occupational disease.

In our laboratories, the eight known antigenically different types of leptospirae in North America were classified by comparison with

By William S. Gochenour, Jr., D.V.M., deputy director, and Robert H. Yager, D.V.M., director, veterinary division, Army Medical Service Graduate School, Walter Reed Army Medical Center, Washington, D. C.

North American leptospirae

Antigenic group	Hosts	Transmission to man
<i>Leptospira bataviae</i> -----	Mongoose, rats, mice-----	Contaminated water.
<i>Leptospira pomona</i> -----	Cattle, swine, horses (serologic)---	Contaminated water. Contact with infected animals.
<i>Leptospira autumnalis</i> -----	Unknown-----	Unknown.
<i>Leptospira ballum</i> -----	Rats, mice-----	Contaminated water.
<i>Leptospira canicola</i> -----	Dogs-----	Contact with infected animals.
<i>Leptospira icterohemorrhagiae</i> -----	Dogs, mongooses, rats, mice-----	Contact with infected animals. Contaminated water. Contaminated working areas.
<i>Leptospira pyrogenes</i> -----	Rats, mice-----	Contaminated water.
<i>Leptospira hebdomidis</i> -----	Mice-----	Contaminated water.

known type strains. First, the cross agglutination-lysis patterns were established for the type strains available. This permitted the selection of antisera prepared against a limited number of leptospiral strains to be employed as a rapid screen in preliminary typing of leptospiral isolates. The preliminary typing was followed by comparison of the unknown with all members of the broad group whose antisera reacted with it. Definitive identification was often accomplished only by agglutination absorption after this second cross agglutination-lysis examination.

Cross complement fixation studies employing the sonic-vibrated and the egg-propagated complement-fixing antigens demonstrated no significant difference in sensitivity or antigenic spectrums between these two antigens. Both are extremely valuable in establishing leptospirosis per se, but the broadness of their antigenic spectrums mitigates against their use in the classification of leptospiral strains, thus precluding their use in epidemiological surveys.

Cross complement fixation studies employing soluble antigens have demonstrated these antigens to be highly strain specific. Comparative typing of more than 100 cultures by agglutination-lysis and by cross complement fixation employing soluble antigens reveals the latter technique to be as reliable as the former, with the added advantages of greater ease and rapidity and the elimination of the hazard incident to the use of living antigens.

Basis for Preventive Measures

Although classification of leptospirae must ultimately rest upon their antigenic charac-

teristics, each identification should be used in connection with known or reported hosts for these strains and with information of occupational or other hazards of infection as the basis for preventive public health measures.

The accompanying table lists the known hosts of North American leptospirae and the most common means of transmission of infection to man. Two strains, *Leptospira icterohemorrhagiae* and *Leptospira canicola*, are harbored by the dog, thus providing an occupational hazard to veterinarians and kennelmen.

Leptospira pomona has been found to date only in the large domestic animals and man; consequently, prevention of spread of this infection is primarily a livestock problem. Control of the other leptospiroses must rest upon rodent and small carnivore control and improved sanitation.

Foot-and-Mouth Disease In Saskatchewan

At the present, only the United States, Australia, New Zealand, Ireland, and, we now believe, Canada can be classed as free from foot-and-mouth disease, which reached pandemic proportions in most European countries last year.

The cause is a virus, of which there are known to be six distinct immunologic types—A, O, C,

By T. Childs, D.V.M., veterinary director general, Health and Animals Division, Dominion Department of Agriculture, Ottawa, Canada.

and three recently identified African types. There are variants within types. Type A was responsible for the 1951 outbreak in Canada.

Radical control and eradication measures are mandatory in Canada. Herds and premises suspected of infection are placed under close quarantine. The animals involved are disposed of by slaughter and deep burial, and the premises are cleansed and disinfected, remaining under close quarantine for 30 days or more. Then, test animals are installed under quarantine and observation until we are satisfied the premises are free of infection.

Foot-and-mouth disease appears to have been implanted either innocently or maliciously by an immigrant from a farm in Western Germany during his employment as a dairy helper in November 1951 on the L. T. Wass premises 34 miles northeast of Regina, Saskatchewan.

The condition was not correctly diagnosed until February 19, 1952, largely owing to the apparently mild nature of the disease, the negative results of horse inoculations, and the preposterousness of thinking the disease would be found in that location. Quarantine imposed on individual premises upon discovery of the disease was apparently very effective in preventing greater spread, hence, the economic results were not greatly altered by the late diagnosis.

Although we are convinced that foot-and-mouth disease has been decisively defeated in Canada, we have no intention of relaxing vigilance. Our veterinarians have examined about 2 million cattle, swine, and sheep since February 18, 1952, with negative results to tests. The number of animals destroyed because of infection, exposure, or suspected exposure is 1,343 cattle, 97 sheep, 1 goat, 290 swine, and 2,142 poultry. Twenty-nine of the 42 premises involved were classed as infected, and 13 were classed as exposed.

To prevent a recurrence, we now require that all immigrants from countries where foot-and-mouth disease is prevalent produce a satisfactory certificate of disinfection for their clothing and personal effects before receiving visas to immigrate. Also, all parcels from such countries are closely examined by our postal and express officials; and if there appears to be doubt about their contents, particularly if ad-

ressed to a farm worker, the parcels are held for examination by a government veterinarian. We require all railroad stock cars and livestock-carrying trucks to be cleansed and disinfected after unloading livestock. Since April 1, 1952, all public and packing plant stockyards and feed lots throughout Canada have been thoroughly cleansed and disinfected under governmental supervision.

Infectious Canine Hepatitis

—A Symposium—

Infectious canine hepatitis is widespread and has a high rate of incidence in the dog population. Only in recent years, however, has it been recognized as one of the most serious infectious diseases of small animals. Knowledge has rapidly followed the proof of the existence of infectious canine hepatitis (1947) as a definite clinical entity caused by a specific virus. The probable natural route of the infection has been established, the source of the virus for spread determined, further information of its disease potential accumulated, and a rational immunization procedure evolved.

By J. A. Baker, D.V.M., Ph.D., director, J. H. Gillespie, D.V.M., associate professor of bacteriology, and G. C. Poppensiek, D.V.M., research associate, Veterinary Virus Research Institute, Cornell University, Ithaca, N. Y.; H. D. Stephenson, D.V.M., professor of therapeutics and small animal diseases, New York State Veterinary College, Ithaca, N. Y.; W. H. Riser, D.V.M., practitioner, Skokie, Ill.; and J. H. Mark, D.V.M., associate professor of medicine, School of Veterinary Medicine, University of Pennsylvania, Philadelphia. Dr. Baker acted as moderator; Dr. Gillespie discussed the clinical aspects of the disease; Dr. Riser, pathology; Dr. Mark, epizootiology; Dr. Poppensiek, immunology; and Dr. Stephenson summarized the papers.

Clinical Features

Clinical observation and experimental findings have indicated a difference in severity of the illness in individual dogs studied—from a slight fever in some dogs to a moderate or severe reaction terminated in some cases by death. As shown by complement fixation tests, an average of 50 percent of dogs have had hepatitis. Bruner and co-workers have indicated that 12 percent of naturally infected dogs died. Percentages are on the basis of incidence determined by complement fixation test in relation to autopsy findings. About the same percent have died from the disease experimentally induced.

Clinically it is difficult to differentiate infectious canine hepatitis from distemper in the acute stage. High "saddle" temperatures, leukopenia, malaise, conjunctivitis, lack of appetite, tonsillitis, and extreme thirst with vomiting, diarrhea, jaundice, and difficulty in breathing characterize the disease. All symptoms may not appear in any one case. Corneal opacity develops in 25 percent of convalescent dogs. This cloudiness may involve one or both eyes for varying periods and then disappear completely. A few dogs with spontaneous illness show cerebral symptoms. No nervous symptoms have been reported in dogs with experimental hepatitis.

Simultaneous infection of dogs with the virus of infectious canine hepatitis and with distemper produce an illness more severe than either virus alone. Dogs that have been inoculated with distemper virus and then been given infectious hepatitis virus afterward show illness in severity comparable to simultaneous infection. Dogs that recovered from hepatitis first did not show this conditioning effect with later infection by distemper virus.

Pathology

Four clinical forms of infectious canine hepatitis are postulated based on the classification of Parry and Larin: (a) fatal, fulminating form; (b) severe, nonfatal form; (c) mild form; (d) inapparent form. Pathology as described here applies primarily to the symptoms and lesions found in the fatal, fulminating form.

The virus is selective in the tissues it attacks. The primary destructive changes occur in the blood vessels and the hepatic cells. The clotting time of the blood is markedly decreased. Such lesions as intraocular hemorrhage, bleeding in the oral cavity, hemoperitoneum, paintbrush ecchymosis of the gastric serosa, and hemorrhagic lymph nodes are produced. The liver appears normal in size but is usually discolored. Many of the hepatic nuclei contain inclusions. The gall bladder wall swells and thickens. The blood clots with difficulty. Positive diagnosis can be made only by histological study of sections from the liver tissues.

Epizootiology

The epizootiological features of infectious canine hepatitis present marked differences from other infections commonly met in small animal practice. The virus is not an airborne one. It can be spread by direct contact, ingestion of saliva from infected dogs, parenteral injection, and by infected urine from dogs that have recovered from the disease. A matter of 6 inches between susceptible dogs and infected dogs is, however, an effective barrier to the transmission of the virus.

As early as 1937 experimental transmission of a presumed type of distemper was recorded in the United States. The description of the original case and the histopathology of the infected animals show remarkable similarity to the present concept of infectious canine hepatitis. That the epizootic fox encephalitis and the virus of infectious canine hepatitis were one and the same was confirmed in 1947.

The virus disappears from the blood at the end of the fever and leukopenia but has been recovered from the urine from 3 days to at least 6 months after inoculation or production of the disease. Evidence points to the fact that the elimination of the virus is through the kidney. Every precaution should be taken to prevent the spread of this disease, which seems to be on the increase.

Immunization

Since simultaneous infection with the virus of distemper and the virus of infectious hepatitis is frequently fatal, the need for immunization is apparent.

Infections caused by the swine erysipelas organism, *Erysipelothrix rhusiopathiae*, result in acute dermatitis with marked erythema on the hands and wrists. The condition is not common even in butchers, meat handlers, and veterinarians, the occupational groups most frequently exposed to infection.

Epidemiology of Rabies

PHR A disease of animals and man that resembled rabies was described in 3000 B. C., and about 500 B. C., the first adequate description of the disease was recorded. Pasteur's studies in the nineteenth century influenced the thinking of the world on rabies, but diagnosis was not established on a sound basis until 1903, when Negri discovered in the motor cells of the central nervous system the intracytoplasmic inclusion body which bears his name and which is considered as pathognomonic of the disease.

The etiological agent of rabies is a filterable, submicroscopic virus which varies in virulence and in immunogenic capacity. Rabies is usually transmitted through the bite of a rabid animal, and pathogenesis is believed to be neurogenic. The incubation period may vary from a few days to 6 to 9 months.

The vampire bat is the only known carrier of rabies. All attempts to demonstrate the carrier state or to create a carrier state experimentally in other animals have failed thus far.

With the exception of Australia, New Zealand, and Hawaii, which have never had rabies and where strict quarantine regulations are enforced, rabies is found in all climates and in all types of ecologic communities of warm-blooded animals. In the United States, rabies may occur at any time of year.

By Raymond Fagan D.V.M., M.P.H., veterinary epidemiologist, Kansas City field station of the Public Health Service Communicable Disease Center.

RABIES IN UNITED STATES—ALL SPECIES

Immunization undertaken approximately 30 days prior to exposures will usually induce resistance lasting one year, and perhaps as long as two or more years, but there is no reliable evidence that vaccine given after exposure to virulent rabies can protect against a clinical attack of the disease. However, evidence is accumulating that hyperimmune antirabies serum given after an exposure will so alter circumstances that vaccine can be used with efficacy.

Within specific areas rabies incidence shows definite peaks and valleys, but as yet no analysis has been made of the factors which contribute to the dynamics of these epidemic curves.

Rabies Control

Two procedures are available to control rabies: prevention of contact between infected animals and susceptible animals, and reduction of the number of susceptible animals within an area. Leash laws, which, if enforced, prevent contact between infected animals and susceptible animals and man, have been virtually abandoned in the United States, leaving only the second method of control—reducing the density of susceptible individuals.

With some species of wildlife, attempts at control of numbers have succeeded in stabilizing the population. However, mere increase in numbers of animals, even when the rabies virus is present, does not mean an epizootic of rabies. Although epizootics and large wild animal populations seem to be associated, sporadic outbreaks do not justify extensive control operations.

In cities, control measures consist of enforcing leash laws and picking up stray dogs and/or vaccinating pet animals on either a voluntary or compulsory basis.

In controlling rabies in both wildlife and domestic animals, one type of program may be successful in one area and not in another.

Some veterinary administrators advocate that all clinical cases of rabies seen by veterinary practitioners be reported to a collecting agency. However, the present practice of having the diagnostic laboratory work on individual cases and report positive findings seems to be completely adequate.

Will Vaccination of Dogs Control Rabies?

In 1946, when I started working for the New York State Health Department, we tried to get dogs vaccinated wherever the rabies problem existed. In the central section of the State, we succeeded in getting 70 percent of the dog owners to comply. With rabid foxes biting and infecting cows and other animals, we knew that rabies continued in the district. Eighty-two rabid dogs were reported. Ten were "strays," and we didn't know if they had been vaccinated. Only 2 of the remaining 72 had been, showing that the vaccine must have been effective.

We do know that vaccine doesn't protect every dog. There are differences in dogs—some just don't produce protective substances in their bodies.

The individual wants to protect his pet. With vaccination, the chances of infection are nine to one against infection. The purpose behind compulsory vaccination laws is to get large numbers of people to vaccinate their pets.

Vaccination should be sold on its merits. There is no State in which the rabies problem is found throughout the entire State at any one time. I prefer to expend energy in getting dogs vaccinated where there is a rabies problem. Effort is wasted and limited, in my opinion when compulsory vaccination laws require it to be diffused over areas where the problem exists as well as where it doesn't.

If the disease is confined to dogs, as it is in large urban areas, rabies can be controlled in 6 months or less by "dog control"—where the owner keeps his pet leashed—by vaccinating 70 percent or more of the dogs, or by a combination of both measures. But we can vaccinate dogs until the cows come home, and the problem will still exist because we can't vaccinate or control the movements of foxes. Rabies is spread from one animal to another in the same way a baton

By Alexander Zeissig, D.V.M., formerly communicable disease veterinary consultant, New York State Department of Health, Albany.

is passed from one runner to another in a relay race—it doesn't spend any time whatever outside the animal body. If we remove 7 of every 10 foxes in an area by systematic trapping, we obtain the same result as by vaccinating 70 percent of the dogs. Such a systematic reduction of the numbers of wildlife has proved effective in New York State and elsewhere.

Salmonella Infections In Chickens and Turkeys

PHR The poultry industry is still plagued by the economic loss caused by one or more of the salmonellas. Probably because of their insidious nature, the relative importance of pullorum disease, fowl typhoid, and paratyphoid infections is frequently underestimated.

Pullorum Disease

In the control of pullorum disease, we are intimately concerned with a cycle of infection in which the mature carrier is the important link. Early in its history, the desirability of combating pullorum on an organized basis was recognized. By 1921, Connecticut, New Hampshire, Massachusetts, and Maine had set up voluntary control programs, the basic features of which were the testing and retesting of breeding flocks, removal of reactors from the farm, clean-up and disinfection of premises, and purchase of replacement stock from clean sources. The National Poultry Improvement Plan, initiated in 1935, included a program of pullorum control, and in 1943 a similar nation-wide control program was extended to turkey flocks. The working basis of the national plan is cooperation under a memorandum of understanding between the several States and the United States Bureau of Animal Industry, and volun-

tary participation under appropriate agreements between hatcheries and flock owners and an official State agency.

All States with the exception of Nevada have signed memorandums of understanding with the bureau. The work at State levels embraces 4,389 chicken and 895 turkey hatcheries, nearly 37 million breeding birds in more than 100,000 chicken flocks, and about 2¼ million turkeys in 3,920 flocks. Tube and rapid serum testing is done in 82 pullorum testing laboratories. Approximately 88 percent of the whole-blood testing is performed by 4,000 pullorum testing agents in the States.

A reduction in the percentage of reactors on first test of hatching-egg supply flocks is one way of measuring progress. The percentage in 1936 of reactors among 4,329,363 chickens in 9,119 flocks was 3.66; in the year ended June 30, 1951, it had declined to 0.54 among 36,843,630 birds in 100,471 flocks. Similar progress has been made with turkeys: the percentage declined from 2.0 in 1944 to 0.36 in 1951.

A more satisfactory but less measurable indication of progress is the livability of the chicks and poults produced under the control programs. Surveys covering 8,389,572 chicks in eight States in 1951 show a mortality for the first 2 or 3 weeks from all causes of 198,841 chicks, representing an average livability of 97.64 percent. Comparable figures are not available for turkey poults. In reviewing laboratory records, we note a diagnosis of pullorum disease in chicks and poults which is traceable to infected parent flocks under the control program. This may indicate reinfection of the flock, or it may mean a lack of diligence in the testing program.

We may anticipate, on a nation-wide basis, a further reduction in the incidence of reactors and possibly a slight increase in average livability. There should be closer cooperation between the testing program and the diagnostic and research laboratories. The true pullorum status of flocks can only be determined by the laboratory upon consideration of the flock history, the character of the reactions, and the cultural examination of representative reactors.

The incidence of infection by *S. pullorum* variants should not be overlooked. The find-

By L. C. Heemstra, D.V.M., veterinary coordinator, national poultry and turkey improvement plans, Bureau of Animal Industry, U. S. Department of Agriculture, Beltsville, Md.

ings of Snoeyenbos and associates in 1951, revealing an incidence of 29.6 percent variant forms in 1,679 cultures from 27 States, emphasizes the desirability of post-mortem bacteriological examination of representative reactors and the typing of all pullorum isolates so that flocks may be tested with properly constituted antigens.

Fowl Typhoid

The incidence of fowl typhoid is apparently increasing, particularly in turkey flocks. Because of full cross-agglutination between *S. pullorum* and *S. gallinarum*, control of fowl typhoid is never entirely divorced from that of pullorum disease. Many chronic carriers of *S. gallinarum* are being eliminated from hatching-egg flocks as pullorum reactors, although the extent of such removal is unknown since only a relatively small percentage of reactors are submitted to laboratories for further diagnosis. There are, however, no organized programs for the control and eradication of fowl typhoid and no provisions in the pullorum control plan which restrict the setting of eggs from infected flocks.

Minimum control measures could be adopted by identifying infected flocks by cultural and serologic methods, by eradication of the disease through the liquidation of such flocks, and/or by abandoning infected flocks as a source of hatching eggs or destroying eggs prior to hatching.

Paratyphoid Infections

We have become increasingly aware of other avian salmonellosis, commonly referred to as the paratyphoid infections. Primarily a problem in turkey flocks, there are numerous reports of their incidence in chicken flocks. The control of paratyphoid infections present a real challenge.

There is nothing to be gained by individual breeders or by State disease control officials in concealing information that certain flocks may harbor paratyphoid carriers, since such flocks are a potential source of infection. We can intelligently plan control measures only when the incidence of the disease is known.

California and Minnesota notably have initiated paratyphoid testing programs in con-

junction with the pullorum testing of turkey breeding flocks. The programs could more properly be referred to as typhimurium control programs since the diagnostic antigens used are primarily produced from strains of *S. typhimurium*.

On the limitations of a paratyphoid testing program, McNeil and Hinshaw emphasize that the primary object of a testing program should be detection of infected flocks and not merely the condemnation of all birds whose serums produce a reaction.

Admittedly, the nation-wide control of paratyphoid infections and fowl typhoid is difficult. When infections occur in breeding flocks, it is not simply the misfortune and responsibility of the owner but the earnest responsibility of the veterinary profession as well.

Poultry Meat Inspection

Although efforts are being made toward wider application and enforcement of sanitation requirements relative to poultry and poultry products, great difficulties are still to be overcome before a satisfactory service can be established. In addition to the need for laws covering both interstate and intrastate activities, the shortage of qualified inspectors is one of the most difficult problems.

Create a New Profession

The creation of a new profession of meat inspectors is one possible approach to this problem. Training for the new profession would include all courses in the veterinary curriculum except therapeutics and clinical and preveterinary training. It might include, in addition, training in general food inspection and sanitation. The course would be on a college level and would probably require 3 or 4 years.

This approach has certain advantages. The course would be at least 2 years shorter and con-

By H. J. Stafseth, D.V.M., Ph.D., head, department of bacteriology and public health, and director, division of biological science, Michigan State College, East Lansing.

sequently less expensive than a course in veterinary medicine. People so trained would qualify only for work in meat, milk, or food inspection and would therefore be apt to make such work their occupation for life.

On the other hand, there are possible disadvantages. The creation of a new profession might discourage fully trained veterinarians, who would still be needed in some positions, from entering the meat inspection field. It brings up the question of a possible demand for starting other "professions," such as poultry disease specialists, "trouble shooters" for feed companies, or sterility experts. Shall we then have a real veterinary profession composed of well-trained men who have a broad understanding of the entire field of animal diseases, or must we dismember it? Would the members of the new profession be recognized as properly qualified food inspectors by the Army and the Air Force? If so, would members of the new profession replace veterinarians or would there be places for both?

Stimulate Interest in Meat Inspection

An alternative solution is to find some way of supplying a sufficient number of veterinary

inspectors. There is no immediate prospect of being able to do so, but within the next few years the chances are very good that with the expected increase in veterinary graduates an increasing number of veterinarians will seek employment in the meat inspection field.

With this in mind, veterinary colleges should make efforts to stimulate interest in meat inspection. Professional veterinary meat inspectors should be included on the faculties as part-time lecturers. Students should be given opportunities to serve as paid "interns" in packing plants during the summer between their junior and senior years. Arrangements should be made to allow senior veterinary students to serve as "food inspectors" in the meat laboratory in the college. The value of meat inspection to agricultural economics and public health should receive special attention.

There are, obviously, no prospects of being able to employ only veterinarians in meat inspection, nor is such a situation desirable. Certainly, technicians or veterinary associates can be trained to perform routine tasks. There must, however, be enough veterinary inspectors to serve as supervisors of all branches of meat inspection service.

Four Hospitals Will Close

Patient admissions to four general Public Health Service hospitals were discontinued in August and September. The hospitals are located in Kirkwood, Mo., Mobile, Ala., Portland, Maine, and San Juan, P. R. They are presently converting their facilities to out-patient clinics as provision is made for patient care elsewhere.

A reduction in Veterans Administration funds which would have provided contract care for veterans hospitalized in Public Health Service facilities led to the recommended closing of the four hospitals. They were selected because their patient load included more veterans and fewer Public Health Service beneficiaries than any remaining Public Health Service facilities. The number of Veterans Administration patients cared for by the Public Health Service will be reduced from 650 to 375.

Financial Resources of Dental Schools

By GERALD D. TIMMONS, D.D.S.

Dentistry in the past half century has rapidly risen from a craft, learned largely through apprenticeship, to the stature of a profession. The evolution of dental education has been guided by an increasing understanding of the biological phases of dentistry and by the recognition of dentistry as a growing science. Laboratory observation and experiment have supplemented the didactic instruction formerly acquired solely through books, lectures, and demonstrations. Rigid supervision has been exercised by the profession itself with respect to standards of instruction. Demands have also been met for continuing postgraduate and refresher training to keep practitioners abreast of new developments in dental science and technology.

The process has been costly. The modern dental school with its laboratories, clinics, equipment, and library facilities bears little resemblance to its predecessor of 50 years ago. In the days when profit-making proprietary schools still flourished, one or two teachers attempted to impart by lecture and demonstration all dental precepts and techniques. Today small groups of students must receive highly individualized supervision in their laboratory and clinical work from specialists in each of the areas encompassed by the modern theory and practice of dentistry.

Dr. Timmons, a former president of the American Association of Dental Schools, and dean of the School of Dentistry, Temple University, Philadelphia, Pa., is chairman of the Committee on the Financial Survey of Dental Schools of the American Dental Association's Council on Dental Education.

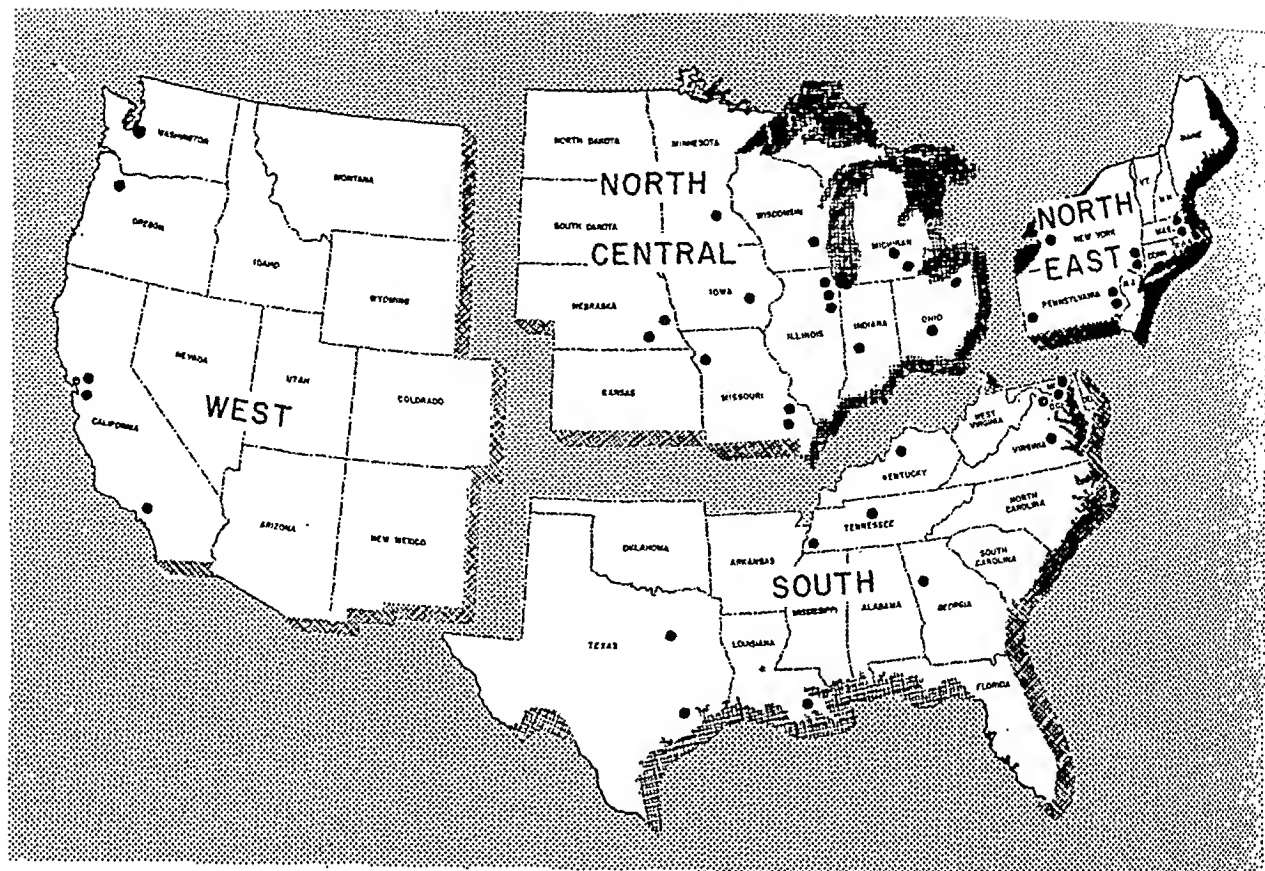

Mounting costs of dental education have been of great concern to dental educators and, in fact, to the dental profession. Dental schools of the United States have found it increasingly difficult to meet the costs of maintaining standards of instruction and research commensurate with the health needs of the Nation and the requirements of the dental profession. The dental schools, moreover, have a large backlog of construction and equipment needs which must be met to relieve overcrowding in their classrooms, laboratories, and clinics. This backlog has accumulated from the low-income years of the depression, from the World War II shortages of labor and building materials, and from the high costs and shortages during the postwar inflation.

Origin and Purposes of the Study

Aware of the importance of an objective appraisal of the financial status of dental schools, the American Dental Association's Council on Dental Education asked the Public Health Service to undertake a comprehensive survey of the situation. The council also, on December 18, 1950, designated a five-member committee to serve in an advisory capacity to the Public Health Service study staff and to interpret the purposes of the study to the deans and other officials of the dental schools. Dr. J. Ben Robinson served as chairman of that committee for the first 8 months and was consultant to the survey staff throughout the period of study. The four other members of the committee were Dr. Otto W. Brandhorst, Dr. Maynard K. Hine, Dr. Robert W. McNulty, and the author, who became chairman in September 1951.

The report of the survey, "Financial Status and Needs of Dental Schools," has just been

Figure 1. Location of 40 dental schools, 1949-50.

published (5). A brief digest of the findings is given here.

Characteristics of Dental Schools

During the study year (1949-50), the United States had 40 dental schools that had been in operation for four or more academic years. One school, that affiliated with the University of Alabama, was not included in the study because it was completing only its second year of operation. Another institution, the dental school of the University of North Carolina, did not open until the fall of 1950.

The 40 schools for which data were collected and analyzed had a total enrollment of 11,359 undergraduate students. The schools were located in 23 different States: 8 in the Northeastern section of the country, 16 in the North Central area, 11 in the South, and 5 in the West (fig. 1). About one-third of the schools had less than 225 undergraduate students, and about one-third had 349 or more. The remaining

third were medium-sized schools (225 to 248 students). About half the total enrollment of all 40 schools was in the group of 13 large schools.

Curriculum

The first and second years of dental education are devoted mainly to work in the basic sciences (anatomy, physiology, bacteriology, pathology, biochemistry, and pharmacology). In addition, the first- and second-year students receive instruction in the principles of operative dentistry, dental prosthesis, oral medicine, and orthodontics. The third- and fourth-year students concentrate principally on patient management, treatment planning, performance of dental operations, and conduct of practice. Any rigid division between clinical and pre-clinical years, however, is rapidly disappearing. In actual practice, the basic science courses are increasingly extended into the clinical years, and clinical material is introduced into the first and second years of study.

University Affiliation and Relationships

Of the 40 dental schools surveyed, 37 were affiliated with a parent university. This affiliation brings to the dental schools the scholastic advantages of association with other branches of higher education. It also carries the administrative and economic advantages of centralized services for plant operation and maintenance, joint use of staff resources and facilities, centralized purchasing, and financial stability.

Two of the nonaffiliated schools operated at a university level in association with schools in other allied health professions; the third was planning affiliation with a nearby university.

University affiliation represents varying degrees of academic and fiscal relationships between dental schools and other departments of the university. Thus, some dental schools (about one-third of the total) carry major responsibility for the instruction of dental students in the basic sciences through their own faculty and facilities. About two-thirds of the dental schools, on the other hand, use the resources of the medical school or other department of the parent university for all or a large part of such training. Sometimes the entire costs of these services are absorbed by the medical school or other university department. In other instances the dental school bears the costs. Since these costs, however met, are a legitimate

part of the total costs of dental education, all schools of dentistry were asked to reflect in the financial data supplied for the survey their pro-rata share of the costs borne by medical schools as well as other university expenditures for instruction in the basic sciences and any other shared expenses. The financial data presented in the report include these expenses.

One of the most significant types of comparison shown in the report and reflected in this summary of fiscal data is the difference between the 25 schools that were privately controlled and the 15 that were public institutions affiliated with universities supported by State or city governments. A trend toward increased support of dental education from State and local funds is indicated by the increase in the number of public schools of dentistry from 12 in 1940-41 to 15 in the study year; in addition the two new schools (in Alabama and North Carolina) not included in the study are affiliated with State universities.

Total Expenses for Basic Operations

Dental schools supplied financial data which permit analysis of expenses for basic operations, for separately budgeted research, and for separately financed postgraduate education. The basic operating expense consists of expenditures for instruction, including clinics as well

Table 1. Amount and percent of basic operating expense by expense item and form of school control for 40 dental schools, fiscal year 1949-50

Expense item	All schools	Public	Private

Table 2. Median basic operating expense by size of school and expense item for 40 dental schools, fiscal year 1949-50

Size of school	Total basic operations	Instruction	Administration and general	Plant operation and maintenance	Libraries
All schools-----	\$378, 253	\$257, 483	\$53, 226	\$43, 670	\$6, 254
Small-----	263, 235	194, 143	39, 857	24, 580	6, 133
Medium-----	378, 253	259, 692	50, 518	48, 482	7, 180
Large-----	435, 294	307, 361	61, 895	62, 667	6, 200

as postgraduate courses and research not budgeted separately; administration and general activities; operation and maintenance of physical plant; and libraries. The widespread adoption by universities of the classification of accounts recommended in 1935 by the National Committee on Standard Reports for Institutions of Higher Education (1) meant that considerable uniformity was found in the form of reporting dental school expenses.

The 40 schools spent \$15.7 million in 1949-50 for basic operations. Of this amount, 69 percent was for direct expenses (faculty salaries, supplies, materials, and equipment for instruction) while 31 percent was for the indirect costs of administration, plant operation and maintenance, and libraries (table 1). The share of

the total instructional expense for dental students borne by other units of the university amounted to \$1.2 million. Medical schools supplied \$1.1 million of this total to 23 dental schools (10 public and 13 private). This amount, as well as the pro-rata share of administrative services received from the university, is included in the total.

The percentage distribution of these expenses among items in the basic operating unit corresponds closely to that found for medical schools in 1947-48 (fig. 2). For both types of institution, instruction (mainly salaries) represented more than two-thirds of basic operating expenses.

Figure 2. Basic operating expense of dental and medical schools.

The median basic operating expense for the schools of dentistry was \$378,253, as compared with a median of \$509,978 for 72 (4-year) medical schools in 1947-48. The median indicates that half the schools spent more than and half spent less than this amount. The median was higher for public dental schools (\$416,258) as a group than for private schools (\$340,929). Moreover, the public dental schools tended to concentrate more closely than did private schools around the median for their group.

The median, of course, gives no indication of the wide differences among schools. Of the 40 dental schools, 4 private and 2 public institutions spent more than \$500,000 each for their basic operations. At the other extreme, 1 public and 4 private schools spent less than \$200,000.

Median expense levels for all items in the basic operating expense, except for libraries, showed progressive increases with increasing enrollment (table 2).

Basic Operating Cost per Student

The essential purpose of translating aggregate basic operating expenses into costs per student is to provide figures that are comparable among schools. Such figures, which are useful in analyzing financial differences among groups of schools, do not in themselves reflect efficiency or quality of instruction.

The median expense per dental student shown in table 3 indicates that public schools, as a group, spent 28 percent more per student for total basic operation and 31 percent more per student for instruction than did private schools. The range in total expense per student was wide. The average for the three schools spending the highest amount per student was \$4,388, a figure

more than five times the average of \$798 for the three schools with the lowest expense per student. More than four-fifths of the 20 schools with the lowest amounts per student were private institutions, while in the group of 12 schools with expenses of \$1,500 or more per student, 5 were private institutions. Expenses per student were inversely related to size of school.

Income for Basic Operations

The basic operating income of dental schools consisted of receipts from tuition and fees, State and city appropriations and university transfers, and income from clinics. In addition relatively small sums were derived from gifts and grants, income from endowments, miscellaneous transfers, and regional organizations. For all 40 dental schools combined, tuition and fees in 1949-50 met over one-third of the total basic operating expense. State and city appropriations and transfers from parent universities provided another third of total expenses. Receipts from clinic services furnished one-fourth of the total, while the remainder came from gifts and grants, endowment income, regional organizations, and miscellaneous transfers.

Great variations were found among the schools in the proportions of their basic operating expenses derived from these different income sources. Tuition and fees supplied 43 percent of the basic operating income of the private schools as contrasted with 22 percent for the public schools. Private schools as a group also relied somewhat more heavily than did public schools on income from clinics. As would be expected, public schools received more than half of their income from State and city appropriations and university transfers. Pub-

Table 3. Median expense per student by expense item and form of school control for 40 dental schools, fiscal year 1949-50

Regional organizations.....	134, 125	16, 500	117, 625

lic funds were included also in the operating income of private schools (table 4). For example the State of Pennsylvania makes biennial grants to many private educational institutions within the State boundaries.

Endowment

A total endowment principal of \$8.6 million earmarked for dental schools was unevenly distributed among 23 schools. Two private schools, each with a general endowment of \$1 million or more, accounted for 86 percent of the

\$5.6 million which represented all general endowment for dental education. Restricted endowment (funds whose income can be used only for a specific purpose) amounted to \$2.8 million. Though more widely distributed than general endowment, it, too, was concentrated mainly in a few private schools, four of which held three-fourths of the total.

It will be recalled perhaps, from the study of the Surgeon General's Committee on Medical School Grants and Finances (2), that medical schools at the end of 1947-48 had a total

Figure 3. Income of private dental and medical schools, by source.

endowment of \$210.7 million. Even discounting the larger number of medical schools than dental schools, the fact that medical school endowment represents a sum 25 times the endowment of dental schools indicates the minor role of endowment income in financing dental education.

The contrast between private dental schools and private medical schools is illustrated in figure 3. In 1949-50, private dental schools, as a group, received only 5 percent of their basic operating income from endowment and from gifts and grants. On the other hand, 40 percent of the basic operating income of private medical schools came from these sources in 1947-48. Figure 3 also shows the difference between private medical and dental schools in reliance on tuition and fees and clinic income to meet basic operating expenses.

Clinic and Other Income

Dental school income has increased substantially over the past two and one-half decades (3). The fact that clinic income has remained a relatively stable proportion of the income of all dental schools combined (fig. 4) suggests rather fixed patterns of fiscal policies in dental education. Receipts from tuition and fees, representing nearly half of the total income of dental schools in 1924-25, had dropped to slightly more than one-third in 1949-50. Other income, mainly university transfers and State and city appropriations, represented only 25 percent of total income in 1924-25 and rose to 40 percent in 1949-50.

Deficits and Financial Needs

The amounts reported by the dental schools as deficits or surpluses for the study year reflect to some degree differences among the schools in the way university transfers are recorded. In their financial reports, 16 schools showed deficits aggregating \$1.6 million. The reports of five of the private schools with deficits showed that each fell more than \$100,000 short of income to meet basic operating expenses in 1949-50.

Unmet needs of dental schools in terms of funds for operating expenses and for construction and equipment were also analyzed. These needs, of course, varied widely from school to

school and at best could represent merely approximations. The aggregates were as follows: \$43 million for construction of physical facilities to relieve overcrowded classrooms, expand clinics, and develop research programs; \$5.9 million to purchase equipment; and, not counting amounts reported as deficits, an additional \$5.5 million for 1949-50 in operating funds to

Figure 4. Trends in sources of dental school income.

maintain and increase staff and to provide for administration and other indirect costs of instruction. At 1952 price and salary levels, this last figure would approximate at least \$8.2 million as the annual amount currently needed for adequate operations.

Separately Budgeted Research

Separately budgeted research is a relatively new activity in dental schools. In the fiscal year 1949-50, the total amount reported by 32 dental schools as expenses for separately budgeted research was about \$733,000. The other 8 schools reported no expenditures for this purpose.

Grants from the Public Health Service to schools of dentistry met 20 percent of the total expenses for separately budgeted research. In all, 15 schools (10 private and 5 public) received these grants from the Public Health Service. Other Federal grants accounted for 24 percent of the total. Industry was the source of 19 percent of the total income for separately budgeted research expended during the study year. Foundations accounted for an additional 15 percent, and miscellaneous sources for the remaining 22 percent.

Postgraduate Education

Most dental schools keep no separate accounts for postgraduate instruction. In all, only 16 schools had separate figures for their expenses for this activity. The total for these schools was about \$370,000, representing \$170,000 reported by seven public schools and nearly \$200,000 reported by nine private institutions.

Conclusion

The report that I have briefly summarized throws light on many of the financial problems in dental education and the difficulties schools face in maintaining high standards of instruction. It provides current data for comparison with that obtained for earlier years by the Council on Dental Education and Dr. William J. Gies (4). In addition, the full report (5) gives a comprehensive analysis of faculty resources of dental schools in terms of full-time equivalents. Certain summary data on schools of dental hygiene are also included.

The report will be read with interest and profit by all concerned with the financial aspects of dental education. The dental profession as a whole will, I feel sure, share the gratitude of

the Council on Dental Education to the Public Health Service for collecting the data, analyzing the findings, and publishing the report.

Environmental Health Center Training Courses

The Public Health Service Environmental Health Center in Cincinnati, Ohio, has announced the dates for two specialized sanitation training courses. Originally scheduled for November 4-7, 1952, the course entitled "Membrane Filter in Bacteriological Analysis of Water" is now scheduled for October 28-31, 1952. "Advanced Training for Sanitary Chemists in Water Pollution Investigations" will be conducted December 1-12, 1952.

Applications should be sent to the Officer in Charge, Environmental Health Center, Public Health Service, 1014 Broadway, Cincinnati 2, Ohio, or the medical director of the appropriate Federal Security Agency Regional Office.

Ideas

Your ideas are too new? Perhaps they need only further application and development to become accepted in public health practice beyond the limits of your health department, your community, or your clinic or your hospital. May we hear from you?

—THE EDITORS

Cooperative Effort

PHOENIX, ARIZ. A cooperative venture in adult education, and the first program of its kind in Arizona put on a continuous basis, the Phoenix Food Handlers School was established by popular request.

The State Restaurant Association, the local hotel and restaurant employees' and bartenders' union, the Phoenix Technical School, and the State and city health departments all sponsor the school as a joint project. It opened early in 1952.

Recognizing the need for classroom demonstrations in sanitary methods of storing, preparing, and serving foods, restaurant association and union representatives took the lead in requesting health officials to set up a training course at the Phoenix Technical School. The four-part course, combining lectures and demonstrations, covers: basic bacteriology, personal hygiene, food-handling techniques, and insect and rodent control. Food-handling certificates are issued upon completion. So far, more than 1,000 catering employees have graduated.

Classes for restaurant and bar personnel had been conducted previously throughout the State, but the new course offers a permanent program. Day and evening schedules permit attendance at convenient hours. A special class is also held for Spanish-speaking people who do not understand English.

Hearing Test Devices

WASHINGTON, D. C. Preschool youngsters can be reliably tested for hearing ability and have fun at the same time through devices developed by M. Lorraine Amos, audiologist at the District of Columbia Health Department audiology clinic, Gales Medical Center. Called the audio-visual stimulus response method, the technique makes use of a clown with flashing red nose, a transparent bunny or Mickey Mouse with light bulb inside, a toy electric washing machine, and the like. The young child is first taught that none of these happy devices will respond to his pressure on the signal button of the sound-producing machine until sound is actually heard through the earphones. Amplified tones that the child is certain to hear and a cut-off switch when the sound machine

By Harry Goodwin—*The Washington Post*.

is not working are used in this preliminary orientation period. Then the actual tests are begun to determine the degree of hearing impairment.

The method carries a great advantage in that children as young as 2 years of age can be tested and given help early enough in life to provide the best results.

Aluminum Caps

WASHINGTON, D. C. Staff members at the Dalecarlia water filtration plant some months ago developed two techniques which save considerable time and expense in processing the fermentation tubes used in bacteriological analyses of water samples.

In place of the sterile cotton plug ordinarily used as a test tube cap, it was found that the unthreaded type of aluminum cartridge case usually provided for 35-mm. camera film could be used. These discarded aluminum cases are available in quantity at photographic shops. They offer the following advantages over the cotton plug: Slightly chipped test tubes can be safely used with these caps; faster manual handling is possible; and the aluminum caps can be sterilized and reused.

In the second technique, a special, large, mechanical washing unit was obtained which allowed assembled fermentation tubes and gas tubes to be cleansed effectively without separating them. This eliminates several time-consuming hand operations.

These two procedures would not necessarily provide advantages in a small water-bacteriological laboratory. However, in a unit such as the Dalecarlia plant, where approximately 100,000 fermentation tubes are processed each year, the saving in time and expense is considerable.

TB Retakes Plus

DALLAS, TEXAS. The retake center of the mass tuberculosis survey is recalling individuals for a large film when the 70-mm. X-rays look suspicious. The center then offers them a screening test for diabetes as well.

Although some refuse the test, often friends and relatives who accompany them to the center will accept. The result—a greater number of persons are screened for diabetes than have retakes.

No publicity is given the auxiliary diabetes test. Each person is asked if he would like to take the test when he is being interviewed for additional information for the tuberculosis survey records.

The diabetic screening is done on capillary blood using the Wilkerson-Heftmann screening test and the Hewson Clinitron.

The Survey Approach to Morbidity And Health Data

By HALBERT L. DUNN, M.D., Ph.D.

It is quite apparent that the field of public health statistics is intrinsically interwoven with that of public health administration. Obviously, the administrator and the statistician cannot fully succeed in their cooperative endeavor unless they agree on the general range and direction of the public health program.

The word "health" carries a connotation of positive well-being. Positive well-being, however, is difficult to measure, and so we usually content ourselves with measuring ill health, or the negative. The World Health Organization has defined health as "... a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity." The principal distinction between public health and curative medicine would seem to be a matter of direction. Public health approaches the problem of illness from the point of view of trying to keep people from getting sick, while the practicing physician is trying to make sick people well. Both concepts are real and necessary. Morbidity statistics and related data are needed both by those who are interested primarily in the prevention of disease and by those whose principal concern is the cure of sickness. Facts must be collected to serve both purposes.

The character of public health is changing.

Dr. Dunn, chief of the National Office of Vital Statistics, Public Health Service, presented this paper (here somewhat abridged) at the Second Conference on Public Health Statistics, School of Public Health of the University of Michigan on June 16, 1952, at Ann Arbor.

Due largely to the effectiveness of public health measures, such as sanitation standards, control of communicable disease, and programs for improving infant and maternal health, death rates in the earlier years of life have been reduced throughout the United States. This has resulted in an older population which is more subject to chronic disease and the disabilities of advancing years. As a consequence, control and prevention of chronic disease are becoming increasingly important and will ultimately become the major element in the public health program—Federal, State, and local. This consideration is of especial significance when it is realized that the ultimate of an aging population will not be reached in the United States for many years.

The steadily increasing average duration of life is not reflected in a corresponding increase in the absolute possible span of life for the individual. Increasing numbers of people will reach the upper limit, but the limit of living will remain substantially the same. Consequently, the goal of public health for these older ages is to preserve as many lives as possible to reach this upper limit of living and to keep the individual fit, active, and free from chronic disease until he dies.

Chronic Disease

As a larger proportion of the population moves into the middle and old age categories, it becomes increasingly necessary to measure the amount of chronic disease and disabilities existing in the community so as to plan and carry out intelligent control programs. This does

not mean that chronic disease is exclusively a problem of old age. Young and old alike become ill for long periods of time and need care and rehabilitation. Chronic diseases, such as rheumatic fever, poliomyelitis, and diabetes, frequently occur in childhood and early adult life.

Not only must the size of the job be measured, but it is particularly important that the job be made as specific as possible. The term "pay dirt," coined in the early search for gold, means concentration areas likely to hold gold. There is also pay dirt in connection with all chronic diseases. Sometimes such concentrations depend upon geographic areas in which cases are clustered. At other times, they depend upon age, sex, race, or other population characteristics. Sometimes a family history of a particular type of disease will be the type of pay dirt which should be sought. However, whether it is the finding of cases, or the conduct of control programs, or health education, vast economies would be effected if such concentrations could be ascertained at the program planning stage. In areas of disease concentration, the intensity of the case-finding and control program should be increased. With less expenditure of money, more could be done to fight chronic disease.

Sickness Data Needs and Types

The need for morbidity data points clearly to the necessity of obtaining more sickness information that will yield valid generalizations applicable to larger population groups which are the subject of program activity or of public or professional interest. Specialized accumulations of data, such as the records of physicians, hospitals, and clinics, are based upon services sought and provided. It is extremely difficult and usually impossible to evaluate how well the sample represents the population in which one is interested. Even facts obtained from birth and death certificates, which are registered for all such events occurring throughout the United States, do not offer an unbiased base from which to extend special studies representative of the United States population as a whole. Such studies would be representative of those families in which births or deaths had occurred. Obvi-

ously, these would not be random with respect to the rank and file of families in the country since, for example, the births would tend to cluster in young families.

There are other types of morbidity statistics which might be employed to measure the amount and character of illness, disability, and injury within a population. Such data come from a variety of sources. Sickness surveys by home visitation have been frequently used by public health workers. In the United States, these surveys have mainly been one-time efforts made for special purposes. Some have been comprehensive, such as the National Health Survey. Some have been periodic and repetitive as, for example, the sample of 9,000 families surveyed in the work of the Cost of Medical Care Committee in 1928-31 and the sample of families in the Eastern Health District in Baltimore studied over a period of years. So far, the United States has never attempted the continuing type of national survey to measure the health of the entire Nation that England has.

Mass diagnostic and screening surveys seemed at first to offer possibilities for limited generalized morbidity information. None of these so far has been conducted in such a way as to permit unbiased generalizations.

A more likely source of useful generalized morbidity data exists as a byproduct of the records of various hospital and health insurance organizations. As these organizations develop, they will presumably progress toward a total population coverage and hold forth the possibility of considerable morbidity data applicable to the population as a whole. Realization of this possibility is still a long way off.

The great majority of morbidity data available to date has come from accumulations of records. It is customary in the fields of medicine and public health to keep records on ill people. The vast accumulations of information in the offices of physicians, in hospitals and health clinics, and in the case registers of health programs offer vital contributions to the fields of medicine and public health. Interpretations however, are largely limited to the immediate purpose for which the data were collected, because usually the records kept involved a highly selected population and consequently cannot be

used to generalize about the population of the community from which the persons were drawn. If this limitation of selectivity of population could be overcome, there is no reason why such accumulations of facts might not be tapped for the broader purposes of public health.

Morbidity Surveys

The Expert Committee on Health Statistics of the World Health Organization at its session on morbidity statistics in November 1951 reviewed these various sources of data and emphasized the possibilities of sickness surveys in providing morbidity data which would be representative of the population. It stressed, in particular, the need for study as to how "sub-samples of hospital records random with reference to the general population" might be used to determine the biases of hospital statistics in ascertaining the level of sickness in the community. The committee came to the conclusion that the survey method has great promise for obtaining various types of needed morbidity data not otherwise readily available and also "for broadening the interpretative base for morbidity data obtained by other means, and for planning health services and health programs."

Evidence points rather definitely to the conclusion that many of the gaps in our quantitative information on sickness and disability cannot be filled except through survey techniques and also that these same procedures hold forth the principal possibility of broadening the interpretative significance of our existing reservoirs of clinical, hospital, and health data. There are, of course, many problems to be solved and questions yet to be answered concerning morbidity surveys. Among these are the following:

What are the needs for morbidity surveys? To what use can they be put? Are there differences between the needs and uses for survey information at the local, State, and national levels? What existing statistical data might be replaced by survey information? What data might be supplemented by such information? To what degree might the significance of existing morbidity data be broadened?

Which of the various types of survey mechanisms available would best suit the purposes

under discussion? At the local level? State level? National level? Would the type of mechanism needed differ for the measurement of health programs in contrast to medical care problems? To what degree should the survey mechanism be continuing or repetitive? When should special studies be made? For what purposes? To what degree could localities or States use national morbidity survey data? To what degree could the Nation or States use local morbidity survey data? Could these data be used if supplemented by special studies? What would be the relative costs of the various types of mechanisms?

What are the principal difficulties facing the fuller use and development of morbidity surveys as a health tool? What difficulties exist because of memory failure of the respondent? Lack of technical knowledge of the respondent? How can nonmanifest disease be discovered? How can unattended morbidity be verified? What difficulties exist in the training of interviewers? Their bias? What are the problems of design?

What is the best method of producing and preserving technical skills needed for morbidity surveys? How can "know-how" be carried over from one survey to the next? How can personnel be trained? Can the personnel of local health offices be used in the collection of survey information? Is it practical for the highly specialized mathematical knowledge needed in survey planning to be located in a national organization and loaned to States or localities for planning surveys?

Should a stabilized and continuing type of morbidity survey mechanism be developed? Should it replace in whole or in part the ad hoc type of surveys of the past? Should it be developed as a governmental or nongovernmental mechanism? As a local, State, or Federal mechanism? Or some combination of these? Should it be under the control of health agencies? If so, where should it be located? How financed? How operated? How used? Should it be entirely consultative? Should it have some regular job of its own to do? If so, what? To what degree should morbidity survey data be gathered for special purposes or as special studies? When and how should a morbidity survey mechanism be developed? What

methodological problems must be solved before a start can be made?

Current Developments

These and related questions are of practical importance and timeliness. Already a number of groups and organizations are actively interested.

The conclusions of the morbidity conference, held in November 1951 as a part of the third session of the Expert Committee on Health Statistics of the World Health Organization, have now been accepted by the World Health Assembly and are being circulated to the member nations. Some of the more important recommendations of the expert committee are that .

1. National agencies responsible for health or health statistics establish within their organizations a group of experts—in sampling theory, in the operation of field surveys, and in the analysis of morbidity data—who can utilize survey methods in the investigation of the varied health problems with which such agencies are confronted and that they make the services of these experts available for consultation throughout the nation and for international purposes.

2. National committees on vital and health statistics, or their equivalents, and other national health organizations undertake or promote studies of the methodology and procedures for the validation of surveys and the data obtained by them, including such problems as interview design, response error, interviewer bias, and methods of verification of diagnostic information both for medically attended and medically unattended illness.

3. Studies be made of the possibility of utilizing survey methods and sampling procedure to tie together information obtained from the general population and morbidity data in existing records of hospitals, clinics, and similar sources.

4. National committees on vital and health statistics, or their equivalents, of Canada, Denmark, India, Japan, Switzerland, the United Kingdom, and the United States make a preliminary report on these survey methods to be distributed by WHO to the other national

committees on vital and health statistics, or their equivalents.

Several years prior to these recommendations by the WHO, the United States National Committee on Vital and Health Statistics, appointed by the Surgeon General of the Public Health Service at the request of the Department of State, set up a subcommittee to study morbidity survey problems. This subcommittee is now at work and hopes to bring forth concrete recommendations by the end of 1952. During five meetings held in the past year, the subcommittee has approached its task by drawing up a list of the major categories of need for morbidity statistics—not only the needs of the Federal Government, but also those of State and local health jurisdictions, voluntary health agencies, and business.

It has been considering what these uses imply as to the types of statistical measures, the geographic and diagnostic detail, the frequency of collection, and the requirements for accuracy, which must be obtained in order to serve the various needs for statistics.

With the types of statistical measures, detail, frequency of collection, and accuracy established, the subcommittee has come to the conclusion that it can set down the outline of a plan of collection which will provide the desired statistics with the required accuracy. Some progress has already been made on this phase of the work, and an outline of a plan has begun to emerge. This plan calls for periodic national surveys and a series of special studies to link morbidity statistics to needs for medical care services, facilities, and personnel.

The Public Health Conference on Records and Statistics has faced some of the problems of morbidity surveys through its working group on general illness statistics. At its meeting in March 1952 the conference endorsed and sponsored the creation of a clearinghouse on current morbidity statistics projects. In this action the conference received the approval of the Association of State and Territorial Health Officers and of the American Medical Association. This clearinghouse will have as its two objectives: (a) the provision of a systematic method for informing workers in the public health and medical fields where they may obtain specific data on human morbidity; and (b) the estab-

lishment of a convenient means whereby workers who are planning studies or surveys involving the measurement of illness, disease, injuries, or impairments can get in touch with colleagues undertaking similar tasks.

For a project to be included in the clearing-house listings, it must satisfy certain criteria. It must be concerned with statistics of illness, disease, injuries, or impairments, and it must have a valid population base so that rates of incidence or prevalence can be stated for the whole of the population studied.

The Public Health Service has recently taken steps to ascertain whether a current health survey mechanism should be created within its organization and, if so, what form this development should take. The Surgeon General has assigned the responsibility of studying this

problem to a committee which represents each of the four bureaus of the Public Health Service and, at the invitation of the Surgeon General, the Children's Bureau will collaborate in this study.

Conclusion

It is time for public health to develop a reliable and continuing mechanism for conducting health surveys. Although there are innumerable questions to be answered as to what form such a mechanism should take, it is evident to many that gaps in the quantitative knowledge concerning sickness cannot be filled unless this step is taken. In particular, the action programs of public health need the availability of such a mechanism to enable the health administrator to plan wisely and to spend his health dollar to the best advantage.

Sewage Treatment Plants

During the second quarter of 1952, 144 cities in the United States invested \$41.8 million in sewage treatment plant projects, according to a report released September 17, 1952, by the Public Health Service.

The report indicated that the number of contracts awarded was 30 percent higher than for the first quarter of 1952 and that the dollar value of the contracts was 50 percent greater. However, the total dollar value for the first half of 1952 was about the same as for the first half of 1951.

The 144 projects are located in 36 States and the District of Columbia. Seventy-five of them are new plants, and 69 are replacements, additions, or enlargements. The dollar value of the projects ranges from \$2,000 for a new plant in Rio Arriba County, N. Mex., to \$7,000,000 for a new plant in the Northern Kentucky Sanitation District.

A complete list of the projects may be obtained from the Division of Water Pollution Control, Bureau of State Services, Public Health Service, and information on specific projects may be obtained from the State water pollution control agencies.

Sampling and Field Procedures of the Pittsburgh Morbidity Survey

By DANIEL G. HORVITZ, B.S.

It is clearly recognized that an accurate evaluation of a community's health status requires more than an analysis of mortality data or reports of communicable disease. The lack of current information on the incidence and prevalence of illness and on other health problems in Pittsburgh led to establishing the "Arsenal study area" for concentrated investigation.

During July 1951, the department of biostatistics of the Graduate School of Public Health, University of Pittsburgh conducted a morbidity survey, on a probability sample basis, of households located in the Arsenal study area. First in a planned series of morbidity studies in Pittsburgh, the survey had four objectives: foremost—to provide general measures of the health status of the household population through the collection of data on recent illness, hospitalization, and accident experience; second—to characterize the population under study through the collection of basic social and economic information; third—to provide a general picture of the pattern of demand for health services; and fourth—to furnish the

nucleus of families to be followed for long-term studies.

Of a total probability sample of 2,954 dwelling units in the Arsenal study area, completed schedules were obtained from 2,791 households, or 94.5 percent. A second sample of 1,629 dwelling units, representing 1 percent of those eligible, was selected from the rest of Pittsburgh. However, this report will be limited to the Arsenal study area sample. It will describe sample and field procedures employed and will discuss the results of a preliminary investigation of both sampling and nonsampling errors.

General Description

The Arsenal study area is a section of the Arsenal health district, the first of five health districts to be established by a reorganization plan of the Pittsburgh Health Department. Its location is shown on the map. The study area comprises 22 of the 194 census tracts in Pittsburgh. Final 1950 census population figures yield 81,785 persons in the study area. Age figures of this population distributed by sex are not available for 1950. However, comparison of the probability sample with 1950 census data for all Pittsburgh shows no striking differences. These data are presented in table 1.

Preliminary 1950 census data for Pittsburgh (1) indicated that 95.42 percent of the population lived in dwelling units, as defined for the census, with 3.45 persons per unit. When ap-

Mr. Horvitz, assistant professor of biostatistics, University of Pittsburgh Graduate School of Public Health, presented this paper before the Second Conference on Public Health Statistics at the School of Public Health, University of Michigan, Ann Arbor, June 19.

Table 1. Age, by sex, for the Arsenal study area sample ¹ and 1950 census of the city of Pittsburgh

Age (in years)	Arsenal study area sample						1950 census of Pittsburgh

¹ For 2,791 completed interviews.

plied to the population of the study area, these proportions yield an estimated 78,039 persons in 22,620 eligible dwelling units.

The 1940 census had shown 47 percent of the area's households, also as defined for the census, in the lowest quartile of Pittsburgh with respect to average monthly rent, with 28 percent in the highest quartile, and only 25 percent in the combined middle quartiles. The study area, therefore, may be considered to be well below the rest of the city in income level.

Personal interview with the housewife or other responsible member of each household selected for sampling produced the survey data which included, in addition to the usual demographic characteristics, information for time periods preceding the date of interview as follows:

Prior month—illnesses; and services of physicians, hospitals, and clinics.

Prior year—hospitalizations; accidents or injuries requiring hospitalization or a physician's care; and services of specialists, dentists, public health nurses, and clinics.

Design and Method of Sampling

Because no accurate lists were available of the eligible dwelling units in the selected area, a design using area sampling was adopted (2). First, 468 census blocks (1940) were classified into three strata according to the number of dwelling units occupied in 1940: stratum I—

large blocks, 100 or more; stratum II—medium blocks, 50 to 100; stratum III—small blocks, less than 50 (see table 2).

Blocks which in 1940 had no occupied dwelling units, or "zero" blocks, were joined with nonzero blocks. Where examination of building permits issued after January 1, 1940, revealed sufficient construction, certain blocks were reclassified. One entire census tract, which had changed greatly since 1940, was cruised by automobile to estimate the number of occupied dwelling units.

To insure a better spread of the sample over the area, we designated blocks as the primary sampling units, and introduced the individual dwelling as the subsampling unit within the selected blocks. Our decision to subsample the blocks meant listing all eligible dwelling units in each block, a task which was performed by enumerators.

Because there were no published data on the amount of variation between blocks and between households within blocks for characteristics of illness and hospitalization for specified periods, we had no basis for estimating the optimum proportion of blocks and of households to be sampled in order to achieve a specified precision. To lead to an approximation of such proportions, we adopted a method suggested by Hansen (3). The method includes the use of the same proportion of sample households for all strata. Determination of this pro-

portion requires a decision on the total number of households to select for the sample.

Since the size of sample to be selected depends upon the phenomenon to be studied, we based the sample size on estimates from other surveys of the rates for number of persons hospitalized per 1,000 population per year and number ill in the course of a month per 1,000 population. These rates are within the order of magnitude of the other phenomena examined in the survey. We also decided that the size of the sample should be such that the observed rate should not differ by chance from the true rate by more than 10 percent. In the light of these considerations, and assuming random sampling, a sample of 8,900 individuals was determined, but it was arbitrarily enlarged to 10,000 to adjust for the actual plan of sampling blocks and then households rather than individuals in an unrestricted random fashion. By translating the 10,000 individuals into number of households, a sampling ratio of 2 of every 15 dwelling units was calculated, yielding an expected 2,927 households to be sampled.

In selecting the number of blocks for the sample, we included all 36 blocks in stratum I (100 or more occupied dwelling units), for undoubtedly there would be substantial variation between those blocks for the characteristics to be measured. We followed Hansen's (3) scheme in allocating the block and subsampling rates to the strata containing the medium- and small-size blocks. Although Hansen suggests selecting an average of 5 dwelling units from the blocks in the small-block stratum, we selected 9 for two reasons: First, the time al-

lotted for the field work would permit only the listing of about 50 percent of the blocks; second, since the morbidity survey would be directed partly toward specific illness diagnoses—items which occur rarely in the population—it was felt that heavier sampling within the block would improve the efficiency of the survey for these items.

In tables 2 and 3 are shown the block and dwelling unit sampling rates, and the expected and actual number of dwelling units selected from each stratum.

To accomplish the sample block selection, census tracts in the study area were listed with each tract geographically contiguous to the immediately preceding tract. Then, maintaining the 1940 census numerical order of the blocks within census tracts, a list of blocks eligible for selection in the sample was prepared for each stratum. The actual selection was carried out

Table 2. Block sampling summary—Arsenal study area

Stratum	Number of eligible blocks	Estimated number of eligible dwelling units ¹	Estimated average number of eligible dwelling units per block	Block sampling rate (proportion selected)	Number of blocks selected	Actual number of eligible dwelling units in selected blocks
I.....	36	4, 149	115. 2	1/1	36	4, 384
II.....	150	10, 117	67. 4	3/5	90	5, 907
III.....	282	7, 689	27. 3	2/5	113	3, 175
All strata..	468	21, 955	46. 9	51/100	239	-----

¹ Source: 1940 Census, Housing Statistics by Block for Pittsburgh. These data were adjusted upwards where multiple dwellings had been constructed since 1940.

systematically, beginning with a block chosen at random from the list. For example, selection from the small-block stratum was accomplished by choosing two numbers between 1 and 5 at random (since the sampling rate was 2 in 5), and by designating for the sample the blocks with these list numbers plus every fifth block following each so selected.

A systematic procedure, using a random starting point and skip-interval in accordance with the appropriate sampling rate, was also fol-

lowed in selecting the dwelling units to be enumerated in each of the sample blocks.

There are many possible sample designs alternative to that adopted for the morbidity survey. Undoubtedly, there exist schemes for sampling urban populations which would achieve the desired precision at less cost. However, it is impossible to determine in advance the value of reasonable alternative plans in the absence of information essential to the design of efficient sampling systems for morbidity sur-

Determination of the Sampling Rates for the Arsenal Study Area Survey

Over-all Rates

To estimate a true rate of 100 per 1,000, or 1 in 10, from a sample with a small chance that the error of the estimate exceeds 10 percent, the required sample size for unrestricted random sampling without replacement may be

obtained from the formula $n = \frac{N}{1 + \frac{NpC^2}{1-p}}$ where

the quantity N is the total size of the population (sampling units), n is the sample size, p the true proportion possessing the attribute, and C the desired coefficient of variation.

For the survey, we have $p = 1/10$, $N = 80,000$ persons, and $C = .03$, so that the required n is 8,900. By arbitrarily increasing 8,900 to 10,000—to account for the actual plan to select households rather than individuals—the proportion of the eligible individuals desired in the sample is estimated to be $\frac{10,000}{80,000}$ or $1/8$.

This rate was increased to 1 in 7.5, or 2 in 15, to compensate for the nonresponse among those selected for the sample, and since the estimate

from census data of the number of persons residing in eligible dwelling units was slightly less than 80,000.

Block and Dwelling Unit Rates

Steps in the determination of the block and dwelling unit sampling rates for the medium and small blocks, strata II and III, follow:

1. The over-all sampling was set at 2 out of every 15 eligible dwelling units.

2. The expected average number of dwelling units to be selected from the blocks in stratum III was set at 9. Since the advance estimate of the average size of these blocks was 27, the dwelling unit sampling rate within blocks was set at $9/27$ or 1 in 3 for this stratum.

3. Since the product of the block and within-block sampling rates for each stratum must equal the over-all dwelling unit sampling rate of $2/15$, the proportion of blocks to be drawn from stratum III was determined to be $2/15 \div 1/3 = 2/5$.

4. The block sampling rate for stratum II is given by the formula

$$\sqrt{\frac{\text{average size of medium blocks (stratum II)}}{\text{average size of small blocks (stratum III)}}} \times \text{block sampling rate for stratum III or}$$

$$\sqrt{\frac{67}{27}} \times 2/5 = 3/5.$$

5. The proportion of eligible dwelling units to select from each of the stratum II sample

blocks was then determined from the over-all sampling rate to be $2/15 \div 3/5 = 2/9$.

Table 3. Dwelling unit sampling summary—Arsenal study area

Stratum	Dwelling unit sampling rate (within blocks)	Expected sample number of dwelling units	Actual number of dwelling units selected	Number of selected households interviewed	Number of selected households not interviewed	Average number dwelling units selected per block
I-----	2/15	553	576	537	39	16.0
II-----	2/9	1,349	1,322	1,255	67	14.7
III-----	1/3	1,025	1,056	999	57	9.3
All strata-----	-----	2,927	2,954	2,791	163	-----

veys. But the sampling scheme used for this survey does possess features of practical and theoretical importance:

First, it is a probability sampling scheme with respect to dwelling units since the chance of being included in the sample, namely, 2/15, is known for every eligible dwelling unit. Therefore, the reliability of estimates determined from the sample can be assessed from the sample data.

Second, it takes into account, although limitedly, the possible relationship of the measured characteristics to size of block or primary sampling unit.

Third, its procedures are simple to administer and control—the determination of the block and subsampling rates and the sample selection can be accomplished rapidly.

Training of Enumerators

Of 18 enumerators employed for the field survey, 10 were male and 8 were female. All of the males and 2 of the females were medical students at the University of Pittsburgh School of Medicine but had no previous interviewing experience. The other 6 female enumerators, chosen from applicants with and without interview experience, included 2 graduate and 3 undergraduate students at the university and an enumerator experienced in health surveys.

The training program, which ran for 3 days before the field survey, thoroughly covered the survey's purpose, field procedures, interviewing techniques, and schedule. As part of their training, which was also supplemented by an instruction manual covering all aspects of the survey, the enumerators conducted practice interviews.

Field Procedures

The actual field work began June 28, 1951. The Arsenal study area was divided, without cutting across census tract boundaries, into six relatively homogeneous subareas determined to a great extent by natural topography. Sample blocks were assigned at random to the enumerators subject to the conditions that each enumerator's assignment include (a) at least two blocks in each subarea and (b) two large, five medium, and either six or seven small blocks. The latter condition was applied to distribute the work load evenly. The assignments were ordered to insure that the field work would be conducted in approximately the same time period in each subarea.

The sample blocks were assigned at random to permit unambiguous statistical examination of the degree of agreement with respect to the findings among enumerators.

No substitutions by the enumerator were permitted for the dwelling units selected. Callbacks, up to a total of three, were made to sample households not contacted on the first call.

To keep the refusal rate low, Pittsburgh radio and television stations made periodic public service announcements asking the public's cooperation during the field portion of the survey, which had been preceded by newspaper publicity.

Close contact was maintained with the enumerators during all phases of the field work, and frequent meetings were held to correct any errors appearing on completed schedules.

Except for a relatively small number of callbacks, the field work was completed in a little over 4 weeks.

Cost

Actual costs of the various phases of the morbidity survey in the study area, except for the tabulation of the results, are shown:

Preliminary preparation.....	\$475
Printing of questionnaires.....	250
Manuals, maps, other materials.....	243
Enumerator training.....	540
Field work.....	4,840
Enumerators.....	\$3,900
Travel.....	90
Supervision.....	850
Editing and coding.....	2,100
Total.....	8,448
Cost per completed, coded schedule.....	\$3.03

Not included are the salaries of the survey's director and assistant director. No attempt was made to determine the proportion of departmental overhead assignable to the survey. There was no overhead for the field office. Enumerators were paid \$1.25 an hour but were not restricted to an 8-hour day. Two punch cards were coded: one for each household and one for each individual in the sample.

The enumerators kept records of their travel and interview time as well as the total time spent in each assigned block. Of their total field time, 36 percent was spent in interviewing, 10 percent in traveling, and 54 percent in other activities which included listing dwelling units.

Accuracy

The increasing demand for morbidity data on a sample basis emphasizes the need for thorough study of both the sampling and nonsampling errors arising in health surveys of the type we are describing. An attempt partly to fulfill this need, based on the results of the Pittsburgh morbidity survey, is under way. For the present, the type of investigation needed will be illustrated for several problems of methodology by analysis of a single characteristic—the number of persons reported ill for the month prior to interview.

Sampling Errors

In any sample survey, it is essential to evaluate the precision of the results. The equations for calculating precision depend entirely on the

sample design and certain properties of the population sampled.

For the Arsenal study area the sample yielded an estimated 8,121 persons ill in the month prior to interview. The estimated coefficient of variation, or relative standard error, is 4.04 percent. Using a 95-percent confidence interval for the total of persons ill in the study area during the survey period, we were reasonably assured that a complete population count, using the same definitions, techniques, and enumerators, would have yielded a figure between 7,465 and 8,777 ill persons. Since a rate based on the total population is estimated with greater precision than the absolute numbers, the sampling error for the estimated illness rate of 113 per 1,000 persons in the study area quite likely falls within the goal set in advance.

Computation of the sampling precision for the illness characteristic yielded several quantities of importance to the design of future morbidity surveys, particularly to those contemplating similar surveys of urban populations (table 4). In particular, these quantities were the variances, or measures of variability, between blocks and between households within blocks. Prior knowledge of these variances would have permitted an advance estimate of the precision of the results with the specific design adopted. More important, the block and household sampling rates which would have yielded the desired precision with the least expenditure could have been determined.

Examination of the data in table 4 reveals some interesting facts. The between-block variation and the average number of persons ill per block are both almost directly proportional to the average size of the blocks in each stratum. And the average variance between dwelling units within blocks remains reasonably constant over the three strata.

Clearly, there is some advantage to selecting a sample design which takes into account the variation in block size either by stratification or by sampling with probability proportionate to size. However, it does not appear necessary to vary the number of dwelling units selected for the sample with the size of block.

Sample surveys of human populations, and morbidity surveys especially, are costly. Until the experience of past surveys is evaluated and

Table 4. Estimated block and average within-block variances and other data by strata for the number of persons reported ill in the month prior to interview—Arsenal study area

Line	Quantity	Stratum		
		I	II	III
1	Number of blocks-----	36	150	282
2	Average number of dwelling units per block-----	122	66	28
3	Variance between blocks-----	489.5	214.4	80.8
4	Average variance between dwelling units within blocks-----	.40	.42	.35
5	Average number of persons ill per block-----	44.1	24.2	10.3
6	Average number of persons ill per household-----	.362	.369	.365
7	Between blocks coefficient of variation squared (line 3 divided by square of line 5)-----	.25	.37	.77
8	Within blocks coefficient of variation squared (line 4 divided by square of line 6)-----	3.0	3.1	2.6

reported, there can be little hope for the development of methods and techniques which will be entirely satisfactory both administratively and statistically.

Nonsampling Errors

In surveys of this type, there are other sources of error which may cause bias in the results but which would still exist if the investigation had called for canvassing the entire eligible population. They include failure to interview all households selected for sampling, errors of response, and errors attributable to enumerators. Some aspects of these nonsampling errors have been examined for this survey.

For various reasons, 163 households, or 5.5 percent of those selected, were not interviewed. Of these, 67 (2.2 percent) were not contacted during any of the four calls made, and 79 (2.7 percent) refused to cooperate (table 5).

The actual bias in the final estimates from failure to achieve 100-percent completion can be evaluated properly only by interviewing the nonrespondents. Various statistical techniques for alternative treatment of the "not-at-home" problem, a component of the nonresponse error, are available, however (4-6). For the most part, these techniques constitute attempts to control the extent of this error in a given survey. Nevertheless, it is important to the methodology of morbidity surveys to know when it is necessary to apply them. It is therefore pertinent to know for which health characteristics, and to what extent, the results will differ in households available for interview from those not available.

A tentative answer is afforded by examining the differences among the results for the interview households classified according to the call completing the interview (table 6). If the purpose of our survey had been only to obtain a rate for general illness in the survey population, the data in table 6 indicate that a single call might have sufficed. The difference in the illness rate for the households interviewed on the first call from that of all households interviewed is well within the sampling error for this characteristic. The slight tendency for the illness rate to increase with successive calls may or may not be real.

Interviewing a single respondent for everyone residing in a selected dwelling unit is another source of possible bias in a morbidity survey. Accordingly, in table 7 the age specific rates for general illness reported for the month prior to interview are compared for respond-

Table 5. Distribution of selected households by interview classification—Arsenal study area

Interview classification	Number	Percent
Interviews completed-----	2,791	94.5
On 1st call-----	2,090	70.8
On 2d call-----	500	16.9
On 3d call-----	135	4.6
On 4th call-----	66	2.2
Interviews not completed-----	163	5.5
Refusals-----	79	2.7
Unable to contact in 4 calls-----	67	2.2
Respondent unable to answer (language difficulty, deaf, other)-----	9	.3
Dwelling unit vacant on 2d or succeeding calls-----	8	.3
Total households selected---	2,954	100.0

Table 6. Persons ill per 1,000 during month prior to date of interview by number of call on which interview was completed—Arsenal study area

Call No.	Number of persons	Number of persons ill	Persons ill per 1,000
1-----	7,559	848	112.2
2-----	1,621	185	114.1
3-----	394	45	114.2
4-----	175	25	142.9
Total-----	9,749	1,103	113.1

ents and nonrespondents by age groups and sex. Although sampling errors for these rates have not been computed, chi-square tests, which assume unrestricted random sampling, reveal significant differences for all groups except for those males and females in the 15-24 and 45-64 age groups, respectively. Possible alternative hypotheses which might account for these differences have not been examined in detail.

From the data in table 7, it is clear that error might be introduced by depending on a single respondent's report of illness experienced by other members of his household. This source of bias in the returns can be removed by selecting individuals at random for interview rather than households, or by personally interviewing in selected households all respondents above a

specified age. Either procedure would increase the survey's cost. Alternatively, the extent of this bias, if it is real, can be reduced by better designed questions and by improved interviewing techniques. The data shown by no means provide the final answer to the problem. Further investigation of this type of response error is necessary for this and other variables relating to health.

In planning morbidity surveys, the type of enumerator employed is an important consideration. It is essential to the success of a survey that interviewing errors not only be measurable but controllable. Standard interviewing techniques and thorough training in them may easily be insignificant control mechanisms when compared with enlightened selection of type and number of enumerators. As yet, no definite criteria are established for the selection of enumerators for health surveys, although the enumerator assignment plan for the Arsenal study area was introduced in an attempt to solve this problem in part. Random assignment to blocks or primary sampling units, so essential to valid comparison of enumerator groups, also permits their contribution to the total survey error to be measured. Hansen and others (7) discuss this latter aspect and describe a method for determining the optimum number of enumerators for effective control of the enumerator variance.

Table 7. Age specific illness rates per 1,000 for the month prior to interview by sex for respondents and nonrespondents—Arsenal study area

Age (in years)	Male						Female					
	Respondents			Nonrespondents			Respondents			Nonrespondents		
	Not ill	Ill		Not ill	Ill		Not ill	Ill		Not ill	Ill	
		Number	Rate per 1,000		Number	Rate per 1,000		Number	Rate per 1,000		Number	Rate per 1,000
15-24-----	48	2	40	608	29	46	172	33	161	474	36	71
25-44-----	186	23	110	1,154	70	57	927	159	146	433	43	90
45-64-----	155	28	153	731	76	94	584	123	174	262	59	184
65 and over--	69	24	258	204	42	171	141	74	344	137	46	251
All ages--	458	77	144	2,697	217	74	1,824	389	176	1,306	184	123

NOTE: Individuals not responding on age and/or illness and households for which the respondent is unknown are excluded.

Although the enumerator team in the Pittsburgh survey could have been composed entirely of medical students, the necessity for an objective answer to their advantages or disadvantages led to the actual distribution selected. In table 8 are shown the illness rates obtained by each enumerator.

Table 8. Persons ill per 1,000 in the month prior to interview by enumerator—Arsenal study area

Enumerator No.	Number of persons in households interviewed	Number of persons reported ill	Persons ill per 1,000
Male:			
1.....	621	47	75.7
2.....	506	77	152.2

4.....	610	50	82.0
5.....	592	42	70.9
6.....	478	46	96.2
7.....	499	43	86.2
8.....	308	20	64.9
All females.....	4,170	450	107.9
All enumerators.....	9,749	1,103	113.3

¹ Medical students. All male enumerators were medical students.

We made approximate tests of significance among the enumerators by computing the analysis of variance appropriate to the assignment plan (table 9). This analysis indicated the enumerators to be a heterogeneous group with respect to the rates obtained for ill persons per household. However, the rate difference between male and female enumerators is not substantiated as significant (table 8). Although not independent of the comparisons chosen for the analysis of variance, a test of the medical

student rate of 124.3 ill persons per 1,000 and the nonmedical student rate of 89.5 yielded conclusive evidence that the difference in reporting of ill persons to these groups cannot be ascribed to chance. This is not surprising since the female medical students had much more illness reported than the other female enumerators. The remaining comparisons tested revealed significant variation among the illness rates for both the male and female nonmedical student enumerators. The rates for the two female medical students were remarkably consistent, however.

Although limited to a single characteristic—illness—the results of this analysis indicate not only the need but the direction for further study of the response problem. If the response bias in reporting persons ill in households is to be effectively controlled in future morbidity surveys, it is essential to know whether, and if so to what extent, respondents tend to over-report to enumerators with medical training. Conversely, is there a tendency to under-report illness to nonmedically trained female enumerators?

Of further concern in the present survey is the actual contribution of the enumerators to the total sampling variance of an observed mean or total. For an unrestricted random sample of n households with k enumerators,

Table 9. Analysis of variance for enumerator study for number of persons ill per household in the month prior to interview—Arsenal study area

Source of variation	Degrees of freedom	Mean square
Assignment areas.....	5	0.77

Blocks within enumerator-assignment areas.....	131	.43
Households within blocks.....	2,546	.59
Total.....	2,784	.58

¹ Significant at 1-percent level.

² Significant at 5-percent level.

each assigned an equal number of households at random, the total sampling variance of an observed mean \bar{x} is given approximately by

$$\sigma_{\bar{x}}^2 = \frac{\sigma_e^2}{n} + \frac{\sigma^2}{k}.$$

The quantities σ_e^2 and σ^2 denote, respectively, the enumerator variance and the random sampling variance of the average response for each sampling unit for all enumerators.

Although the actual sample design was not of the unrestricted random variety, this formula may be used to indicate the relative importance of the enumerator variance. An approximate estimate of σ_e^2 may be obtained from the analysis of variance table by subtracting the interaction mean square from the mean square for enumerators and dividing by the average number of households interviewed per enumerator. The desired estimate is therefore

$$s_e^2 = \frac{1.96 - .38}{155} = .01.$$

The total mean square in the analysis of variance, or 0.58, may be taken as indicative of σ^2 . Thus, the total sampling variance of the observed mean number of persons reported ill per household for an unrestricted random sample of 2,785 households with 18 enumerators is estimated approximately by

$$s_{\bar{x}}^2 = \frac{.58}{2,785} + \frac{.01}{18} = .00021 + .00055 = .00076.$$

The enumerator variance is, therefore, roughly estimated to be contributing 55/76, or 72 percent, of the total sampling variance.

Although the relative sampling error remains small in this instance, the example does emphasize the importance of evaluating and reporting the contribution of the enumerators to the total survey error, a generally neglected practice. Admittedly, it may not be necessary to do so for many characteristics. Which variables require assessment are not presently known. If the relative magnitude of the enumerator variability had been realized prior to the Pittsburgh morbidity survey, statistical control of this source of error could have been affected by increasing the number of enumerators—if cost of the survey were not an important factor too!

Better criteria for selecting enumerators for morbidity surveys, improved questionnaire design, improved interviewing techniques, and better training methods must be considered in conjunction with the number of enumerators if the enumerator error is to be controlled efficiently.

Summary

The first of a series of morbidity surveys on a sample basis planned for the Arseual study area of Pittsburgh is discussed. The survey design, method of selecting the sample, and field procedures are described in detail. In addition, the accuracy of the findings for a single characteristic—persons ill during the month prior to interview—is discussed with respect to both sampling and nonsampling errors. Particular reference in the discussion of the latter is made to the errors of nonresponse, of respondents, and of enumerators.

ACKNOWLEDGMENTS

The Sampling of Records

By ROBERT E. PATTON, M.P.H.

Public health administrators have been making decisions on the basis of samples for many years. A sample taken from a water supply is examined and a decision is made about the condition of the entire water supply. The potency of a small sample of a vaccine is tested and from the results the potency of the entire lot is determined. A new immunization procedure is tested on a small group, and a decision is made as to whether the procedure should be put into general use or not. The sampling of records is a natural extension of these general sampling principles. Administrative decisions can be made from samples of records with at least as great a validity as those made from laboratory and clinic samples.

Restriction of the topic to the sampling of routine operating records—usually pieces of paper or cards—will simplify this discussion, excluding from consideration the special problems the statistician meets in taking a sample of persons by household interview.

We will assume that whenever we take a sample of a set of records we intend to measure or count something in the sample. From that measure or count we want to estimate the result we would have gotten if we had used all the records. That is the purpose of any sampling procedure—to estimate something about the whole by measuring or counting a part. It may be well to emphasize an obvious point. If the

information necessary for a measurement is not available in a complete set of records that information cannot be put into the records by taking a sample. In other words, the investigator cannot find out from a sample more than he would from a full tabulation. He must realize, too, that all information in the records may not be usable. Frequently, material gathered as parallel or incidental information will not give valid answers.

The word "sample" needs defining. It is a mistake to call just any selection of items from a larger group a sample of that group. Deming in his book, "Some Theory of Sampling," uses the word "chunk" to represent any part of a total population (1). He restricts the word "sample" to mean a chunk selected in such a way that the reliability of estimates made from it can be determined. That is, results gotten from a sample can always be so stated that the reader can know the variability that is due to chance. He cannot always know the variability which must be ascribed to errors of response and interpretation, but he can measure the variability due to sampling.

This does not mean that a sample must always be selected randomly. There are other methods of sample selection for which the sampling error can be determined (2). The first 100 sheets of paper in a pile may be a sample of all the papers in that pile or it may not, depending on the circumstance. The question to ask is: Does each piece of paper have an equal chance of being selected by the method used? If this question can be answered affirmatively, we have a sample. In other words, we must know there is no more likelihood of one particular kind of paper being on top of the pile than of any other. If we can say and prove that any one

Mr. Patton, senior biostatistician of the division of local health services, New York State Department of Health, presented this paper June 18 at the Second Conference on Public Health Statistics, School of Public Health, University of Michigan, Ann Arbor.

of the sheets is as likely to be in the first 100 as any other, we have a sample when we take the first 100.

When should records be sampled? There is no one right answer that will apply to every circumstance. But there are two wrong answers—that records should never be sampled, or that they should always be sampled. It is not a “yes” or “no” proposition. Each specific set of circumstances must determine the answer.

Reasons for Sampling

There are three main reasons for sampling records. The first and most important in the field of public health, certainly, is to save money. When administrators are faced with the need for making the health dollar go as far as possible, the usefulness of record sampling as a money-saving procedure cannot be overlooked. Very often by tabulating only a small portion of a total set of records large sums of money can be saved.

A second reason for sampling records is to save time. The results of a sample tabulation can often be available much sooner than the results of a complete tabulation. In many public health situations timely information of slightly less accuracy is of more value than much more precise information months or years later. An excellent example of this use of sampling of records is the National Office of Vital Statistics monthly tabulation of deaths by cause for the country as a whole, based on a 10-percent sample. By this sampling device NOVS is able to get a national monthly tabulation of deaths by cause into print in the third month after the events occur. This represents a tremendous saving of the time that would be required if all the death certificates had to be coded and processed before the tabulations were made.

The third reason, and one that may seem almost paradoxical, is that more accurate results can often be obtained by using a sample of the records than by using all of them. For instance, if a survey of the quality of obstetrical care given to mothers of infants born in a State during a year were to be made from hospital records, it is possible that a more accurate evalu-

ation could be made by doing a sample study than by looking at all the hospital records. In a sample study the number of records can be kept small enough so that the work can be done by one or two qualified obstetricians who can agree on standards of quality and on how to determine them from the hospital records. However, if the hospital records of all the mothers of children born in the State in a year had to be examined, it would probably be necessary to hire and train clerks for the work. Errors made by the relatively less well-trained clerks could far exceed the errors introduced by the sampling process.

A specific example may prove of interest. In New York State on July 1, 1951, a new birth certificate form was introduced in which the supplementary medical information section was changed radically. The existing supply of old forms in the field was not recalled, but requests for renewed supplies of certificates were filled with the new forms.

By January 1952, it was evident that a large percentage of the certificates arriving at the office of vital statistics in Albany were on new forms, and we were interested in knowing what the percentage for that month was. The certificates received in Albany are numbered and kept in numerical order by registration district and by date within each registration district. There were 12,910 births recorded in January 1952. Thus, the certificate numbers in January ran from 1 to 12,910. It was comparatively simple to pick one of the first 50 certificates at random and mark down whether it was on the old or the new form and then do the same for every fiftieth certificate after that. For instance, if the first one happened to be No. 27 we merely looked at certificate numbers 27, 77, 127, 177, and so forth. This gave us 253 certificates, or a 2-percent sample. In this sample we found 80.6 percent to be new certificates. This percentage has a standard deviation of 2.5 percent so that we are 95-percent sure that the true value lies between 75.6 and 85.6 percent. This was sufficiently accurate for our purposes. The whole job was done in about an hour. Examination of all the certificates would have taken a clerk at least a full day.

In order for any sample to be of value, it is necessary to have some idea of how closely the

results of the tabulated sample agree with the results that would be gotten by tabulating all the data. In sampling, some variation is always introduced. If the sampling is done according to the principles of probability, the size of the sampling variation can be calculated. This is a back-handed definition of probability sampling. Turned around, it means that if the sample is drawn in such a way that the size of the sampling variation can be calculated, then it is a probability sample.

The Random Sample

A random sample is one type of probability sample. However, the word "random" is being used here in a very precise sense. It does not mean haphazard. It means that each element of a particular group or type has exactly the same chance of being selected in the sample as every other equivalent element and that there is no bias in the selection process. We can generalize this concept of randomness and say that the chance of an item falling into the sample need not be equal, but it must be a known chance. As long as this condition is present, we have a probability sample.

How can we pick a sample that is random? The common method is to drop each element into a hat and pick one element out at a time while blindfolded. This supposedly gives a random sample. It is essentially the method that was used to determine the order of induction of draftees prior to the beginning of World War II. Capsules which contained a slip of paper with a number on it were made up, put into a glass bowl, and selected one after another to determine the order in which men would be inducted. A study has shown that this procedure did not give a random result. There was too high a percentage of low numbers in the early draws and too high a percentage of high numbers in the later draws. This can best be explained by the fact that the capsules were carefully put in the bowl in order and evidently were not thoroughly mixed. That this classic example of random selection should have a bias in it is surprising. It does emphasize the fact that thorough mixing or shuffling is essential. Similar studies of bridge hands have shown that ordinary shuffling and cutting practices

do not give a random distribution of hands. A better system of random selection is necessary.

Probably the best method of making a random selection from a series of elements is to number them and then to select the numbers of the elements to be used by a table of random numbers. On this table digits are arranged in a random order. Such a table is produced by using some mechanical device such as a numbered wheel, which is first tested to make sure that it does not have a bias in it. The results of successive spins are recorded in rows. This gives a series of random digits which can be used for many sampling problems. Random 2-digit numbers can be obtained by considering the digits in pairs. In a similar fashion random numbers with more digits can be obtained. The same starting point should not always be used. In fact, the starting point should be selected at random. Such tables are included in many statistics texts and collections of standard tables. When records are sampled, this is not a very practical method since it takes too long to number all the elements and make the selections. Something that will work much more easily and automatically than a table of random numbers is needed.

Systematic Sampling

Systematic sampling is such a method (3). By systematic sampling we mean the process of taking every fifth, tenth, or some other n th item on a list. The first item to take can be determined from a table of random numbers. Then one merely takes every n th item after that. It is the method described in the previous example about birth certificates. The question immediately arises: Is systematic sampling, random sampling? The answer probably is "not quite." However, it is probability sampling since, theoretically, the sampling variation can be determined. If we know something about the order in which the items are listed, we can, in general, tell whether the variation will be smaller or larger than the variation we would get by random sampling. In most practical situations, the variation is smaller in systematic than in random sampling.

This is particularly true if the list from which we are sampling is ordered by some char-

acteristic which is correlated with the characteristic we are studying. When a systematic sample is taken from such an ordered list, we actually get a stratified sample. That is, we get a representative sample containing the correct number of elements from each portion of the list. If a list of last names were in alphabetical order we would get the same percentage of each letter of the alphabet in the sample as in the total list. Suppose the characteristic being measured is in some way associated with the last name, such as size of family. We would then have a smaller sampling variation for a systematic sample of the same size as a random sample.

However, systematic sampling may not work well if the list involves a cyclic pattern. Suppose we have a list of all the dwellings on a street. Suppose furthermore that all the houses on the street were built at one time by one builder and that he put exactly 12 houses on each block. If we took a systematic sample of $\frac{1}{12}$ of those houses we could get either all corner houses or no corner houses in the sample. If we were studying some characteristic related to housing, such as income, the sample would be biased since people with higher incomes tend to live in houses situated on corners. Thus, a systematic sample which is representative for one characteristic may not be representative for another. A completely random sample on the other hand (which might have larger sampling errors) could be used for all characteristics.

But, if a cyclic factor such as the one which might have led to the sampling of corner houses is not present, there is no reason for using random instead of systematic sampling. And systematic sampling can save large amounts of time and money in the actual sampling process.

Sample of Medical Care Services

Two specific examples of how record sampling was actually used may help to explain some of these points. The bureau of public health economics at the University of Michigan was interested last year in studying the experience of Windsor Medical Services (4). This medical care plan, operating across the river from Detroit in Windsor, Ontario, provides physicians' service to about 100,000 in-

dividuals on a prepaid basis. A card record of all the service provided each individual who has a contract with the plan is maintained and filed alphabetically by the last name of the contractor. This contract may cover just the individual or it may cover him and some or all of his dependents. Thus, some cards have one name; most have several.

The study's primary aim was to describe and analyze the services received by individuals in the plan during a year's time. The facilities available did not permit a study of the records of all the 100,000 individuals enrolled in the plan. It was therefore decided to take a sample and to study the services received by the people in this sample. Preliminary calculations showed that the desired data could be obtained by using a sample of about 1,250 individuals. The results obtained from a random sample of 1,250 would have a desired accuracy 19 out of 20 times.

The problem, therefore, was the selection of 1,250 individuals from the 100,000 enrollees. Since some of the cards had more than one name on them, it was not satisfactory to select cards at random from the file. People who had individual contracts with the plan would have had a greater chance of being in the sample than people who were in the plan on a family contract. Since we wanted each individual to have an equal chance of being in the sample, some other scheme had to be used.

The cards on which the services were recorded constituted the only actual list of persons enrolled in the plan. It was not practical to number all these individuals, select 1,250 numbers from a table of random numbers, pick the cards for those individuals, and record their services for the year. The numbering job in itself was far beyond the facilities available.

We decided that systematic sampling was the most practical method to use. If we took every seventieth individual in this file of cards, starting at some random name among the first 70, we would then have a systematic sample of about 1,400 names, which would be satisfactory. However, even this was beyond our limited facilities. To get to every seventieth name in the file would have meant that every single name would have had to be counted, so a further compromise was decided on.

The cards with these names were kept in 30 file drawers. A random selection of $\frac{1}{5}$, or 6 of these file drawers, was made and every fourteenth name in those 6 drawers was selected. Since we had selected $\frac{1}{5}$ of the file drawers and were then taking $\frac{1}{4}$ of the individuals in those drawers, we were sampling at a rate of $\frac{1}{5} \times \frac{1}{4}$ or $\frac{1}{20}$.

By this procedure we got a sample of $\frac{1}{20}$ of all the names in the file, but we only had to count $\frac{1}{5}$ of the names in the file. We could have counted $\frac{1}{10}$ of the file and taken every seventh name, but we did not want more than one representative of the same family to be in the sample.

The results, which were obtained by this method and which could be checked against population values, were well within the expected random sampling variability. This is an indication, but only an indication, that the sampling procedure was adequate. There are two complications that should be mentioned. First, we were interested in all services received by subscribers during a specific year. The sampling was done about 3 months after the end of the year. The file of cards therefore contained individuals who had joined the plan during the year in which we were interested and in the 3 months following. Individuals who came into the plan during the year were accepted as part of the sample if they were selected. However, their date of entrance was noted on the record form, and in calculating the person-months of experience they were only credited with the actual time they were in the plan. If they had joined the plan during the 3 months after the period of study, their names were omitted if they fell into the sample. No other individual was substituted for them.

The second complication was that individuals left the plan during the study year. As they left, their cards were removed from the file and placed in an alphabetical discharge file. To insure that the sample would contain the proper proportion of these people, it was necessary that $\frac{1}{20}$ of all the persons who left the plan during the study year, or in the 3 months after the study year, should be in the sample so that we would have a record of the services they had received. Therefore, a procedure similar to that used on the main file was used on the discharge file. The record of services received

by each individual selected was transferred to a special form which also contained spaces for such items as age, sex, and length of time in plan. From these forms cards were punched, and the desired results were easily obtained by machine tabulation.

Stratified Sample of Townships

Record sampling is also being used in a study now being conducted by the New York State Health Department. Fourteen of the 57 counties in upstate New York have full-time county health departments. The remaining 43 counties do not have organized county health departments. They are served by 15 State district health offices which coordinate the work of county nurses and other locally employed part-time and full-time health personnel. The director of the division of local health services wanted to know whether the people living in the rural and suburban areas were receiving more nursing, clinic, sanitation, or other types of service in the areas where there was a full-time county health department than where there was the combination of State and local services.

One practical way of measuring service was to use the routine operating records normally kept by the various health agencies. The job obviously called for some sort of sampling. There are slightly more than 2 million people in the rural and suburban areas being served by the district system and slightly over 1 million being served by full-time county health departments. To examine all the records pertaining to these 3 million people would obviously be impossible without a large staff and nearly unlimited resources. What was needed was a sample of all the records pertaining to a group of people who would be representative of the entire population being served by each administrative system.

Basically, there were two ways of cutting the records down to a manageable number. One would be to use the records of all the services which people received in a very short period of time—a day, for instance. This would involve many records in every office throughout the State. The variation in the services provided from day to day could be quite large. The second possibility was to take a sample of the peo-

Entomological Survey Methods

By ROBERT E. SERFLING, Ph.D.

Public health entomological surveys are primarily directed toward measurement of the relative abundance of arthropod vectors of human diseases. In the United States these include the mosquito vectors of malaria and dengue, mosquitoes and other arthropods implicated in the natural history of infectious encephalitis, ticks which transmit Rocky Mountain spotted fever and tularemia and which have been implicated in Q fever, certain flies which have a role in the spread of bacteria causing diarrhea and enteritis, rat ectoparasites which transmit typhus, and ectoparasites of wild rodents responsible for sylvatic plague.

The amount of information currently available on the epidemiology of the arthropod-borne diseases varies considerably from one disease to another. The relationship of mosquitoes to transmission of malaria has been worked out in great detail, and a large body of information is available on the habits and behavior of *Anopheles quadrimaculatus*, the only important vector of malaria in the southern United States. For infectious encephalitis, on the other hand, knowledge of the natural mechanism through which the disease affects man, birds, and other animals has many gaps. *Culex tarsalis* frequently has been implicated as a carrier of the virus, but the complete story on this arthropod and others suspected of transmitting

infectious encephalitis remains to be determined. In insect surveys relating to a disease for which the epidemiology has been well worked out, emphasis can be given to quantitative investigation. In a disease for which less information is available, qualitative and descriptive studies of the natural history of suspected vectors take precedence.

In surveys of human populations, advance information on location and characteristics of the population is available, and the subject of investigation is the species with which we are most familiar. Census lists, directories, and other sources of information provide the investigator with data from which he can estimate in advance the range and likelihood of his sampling error.

Comparable sources of information on insect populations do not exist. Collection of insects depends on response of members of the insect population to some stimulus, and the resulting sample is similar to those obtained in "mass surveys," or in some epidemiological surveys in which bubble gum is used to persuade children to be examined.

In an epidemiological study, it would be desirable to obtain quantitative estimates of the vector population to determine the number and proportion of infected vectors and their relationship to levels of human infection. Ross (1) and others have investigated this problem theoretically and have obtained useful general information through arbitrary estimates of the necessary constants, but direct estimates have not been attempted. In applied public health entomology, indexes of prevalence replace estimates of population, and efforts to measure the proportion of infected vectors are beset with many difficulties.

Dr. Serfling, an entomologist, is chief of the statistics section, epidemiology branch, Communicable Disease Center, Public Health Service, Atlanta, Ga. He presented this paper June 19 at the Second Conference of Public Health Statistics, School of Public Health, University of Michigan, Ann Arbor.

The various methods of obtaining indexes of insect prevalence take into account the insect's reaction to light and food, to suitable sites for egg-laying, and to other physiological stimuli. And reactions of closely related insects to such stimuli may differ markedly.

The success of many collecting methods depends on the skill and experience of the collector. Although tests of a collector's ability can be designed, and are sometimes employed, the entomologist usually appraises the collector's skill subjectively. Unless readily evident discrepancies occur, the entomologist accepts the collector's findings.

A description of some common methods of obtaining indexes of prevalence of insects will enable the reader to understand the sampling problems.

Collection Methods

Exposure of human bait provides a direct index of local mosquito prevalence. In one method, the collector drives his car to a collecting point at night, turns on the dome light, removes his shirt, rolls down the car windows, and captures the mosquitoes as they enter and settle upon him. A quantitative index may be obtained by exposure during some standard time interval. This and other "biting catch" methods require a detached interest usually found only in the enthusiast, and for routine collections more prosaic and less direct methods are the usual practice.

The mosquito light trap employs an electric light bulb as an attractant and an electric fan to create a current of air which forces the mosquitoes through a wire net cone into a killing jar. This is a useful device for collecting many species. A disadvantage is that the light source is also attractive to many other insects, and the mosquitoes must be sorted from a hodgepodge of moths, beetles, and bugs. The time spent in sorting out the mosquitoes and identifying the species of interest severely limits the number of collections which can be handled currently.

Anopheline mosquitoes in the United States have a habit of resting during the daytime in shelters near their breeding places or source of food. This trait enables direct collection of adults from sheds, small barns, culverts, and

other structures in the vicinity of human or animal habitations.

However, different collection methods may not yield comparable indexes. Response of a mosquito to an electric light or to a source of blood may be quite different. Light traps, for example, attract anophelines in very small numbers, but they draw some of the culicine species in great abundance. A collection procedure appropriate to the survey objective must be selected and then used consistently. Although the results cannot be taken as a measure of the total mosquito population, they will provide an index of seasonal change or difference in abundance from one area to another.

Mosquitoes may also be collected in the larval stage, and for this purpose the familiar household water dipper is widely used. Use of the dipper must be adapted to the behavior of the species under study, and the collector must be trained to recognize the habitats and behavior of the various species. Some individuals develop the knack of collecting much better than others, and these differences in collecting skill may be great. Ten "dips" are often used as a standard number for inspection of a limited area, but the numbers actually taken may vary widely. The results are useful principally in determining presence or absence of larvae. Anopheline larvae can readily be distinguished from larvae of other groups of mosquitoes, but even highly skilled collectors, thoroughly familiar with the local species, can only recognize a few distinctive ones in the field. The larvae must therefore be returned to the laboratory for identification. This places a limit on the number of collections to be taken.

Flies

For domestic flies, collection of adults is the principal survey method. Although larvae may also be collected, they are difficult to identify and are usually reared to the adult stage for identification.

Flies may be captured by traps baited with materials attractive as food or as egg-laying sites. The housefly and several species of flesh-flies and blowflies are of interest, and mixed baits containing substances attractive to the various species are employed. The traps are usually exposed for 24 hours. The time con-

sumed in setting out the traps and in collecting and identifying the catch limits the number of traps which can be used. As the bait trap competes with natural attractants, interpretation of catch differences from one area to another may be difficult. Bait-trap catches are used chiefly to obtain qualitative information on occurrence of the various species and on broad differences in composition of fly populations.

A device which has been developed and widely used in Communicable Disease Center fly surveys is the Scudder grill (2). It consists of a light framework of slats 36 inches long and $\frac{3}{4}$ -inch wide arranged to form a 36-inch square of parallel slats separated by $\frac{3}{4}$ -inch spaces. The grill was originally designed to provide a light-colored background for estimating numbers of flies in dairies and restaurants but has been adapted by entomologists to many other situations. In use the grill is slipped over an attractant—garbage, manure, or other debris at which flies gather. The flies, disturbed by the grill, rise through the open spaces and settle momentarily on the slats. The inspector estimates the number of flies of each several kinds. Tests indicate that counts are fairly accurate up to about 25 flies. For larger numbers of flies, counts are made of a section

of the grill and the totals are estimated. Variability of estimates of larger numbers is roughly proportional to the total number of flies on the grill. Maximum estimates are of the order of 1,000 flies. In urban surveys 5 to 10 grill readings are usually made in a city block and the five highest counts are recorded. Various statistics have been used or proposed for use on these readings. These include the highest count, the third highest count, and the arithmetic mean or total of the five highest counts. A logarithmic transformation of the data has been found useful in some analyses.

A cruder index is the "visual estimate" technique, in which the inspector examines the attractants in a block and estimates the average grill count for the block. In using this method the inspector makes a grill reading in approximately 1 block out of 10 in order to stabilize his estimates.

Ectoparasites

Fleas, ticks, and lice associated with rats and other rodents are collected in studies of typhus and plague. In typhus investigations the rats are trapped and anaesthetized, and their parasites are combed out, identified, and counted. In studies of sylvatic plague, wild rodents are collected and their ectoparasites pooled for laboratory determination of plague infection. The field survey problem in these diseases is essentially one of sampling animal populations.

To control the dog tick, *Dermacentor variabilis*, vector of Rocky Mountain spotted fever in the eastern United States, a direct measure is obtained of the prevalence of ticks likely to feed on man. For this purpose, a light-colored piece of flannel is drawn along the grass at the edges of pathways and roadways used by pedestrians (3). The ticks attach themselves to the flannel cloth and are counted, providing an index of relative prevalence which is expressed as the number of ticks per 1,000 yards dragged.

Types of Surveys

Communicable Disease Center entomological surveys fall into three classes: (a) exploratory surveys to determine the fauna of an area; (b) surveys to appraise effectiveness of insect con-

Figure 1. Comparison of three indexes of fly prevalence in a residential area having a low sanitation level, Phoenix, Ariz., 1950.

Figure 2. Average of high grill-index of total flies, 3-week moving average. Diarrheal disease control studies, Hidalgo County, Tex., 1946-48. (Redrawn from ref. 4.)

trol operations; and (c) surveys included as part of epidemiological field studies.

Exploratory

In faunal surveys, the contribution of formal sampling techniques is minor. Resources are usually limited, and, although the same logical principles that underlie sampling theory come into operation, decision on choice of collecting method and distribution and selection of sampling sites is made largely through the entomologist's knowledge of the behavior of the insect species and the ecology of the area to be surveyed.

Control Operations

The design of surveys required to appraise control operations must meet a twofold objective: provision of information through which control operations may be directed and appraisal of the effectiveness of control. Fly control operations illustrate the problem. An urban community may be broken into areas with different sanitary levels, but within these areas conditions may fluctuate from week to week. Cast-off garbage, animal feces, dead ani-

mals, and other sources of breeding material for flies may occur in one place one week, in a different place the next. Blocks that are relatively free of breeding places at one examination may be producing large numbers of flies a week or two later.

In 1949 the Communicable Disease Center made a study of fly-sampling methods, using the Scudder grill as an index, and collected data in Topeka, Kans., and Charleston, W. Va. In each city, a series of random samples of paired blocks was selected systematically from an ordered series of block numbers. A different series was examined each week and comparison was made of variances within pairs of blocks and among pairs within sections. The within-pair variances turned out to be of about the same magnitude as the variance among pairs within sections, and it was evident that surveillance as a guide to selective control would require weekly examination of all blocks within the area in which control was to be maintained.

Since the Scudder grill technique was too time-consuming for such extensive surveillance, the visual survey method was introduced, and in 1950 the results were compared with the

results of using the Scudder grill in the field. The urban areas under study were subdivided into units of about 10 city blocks of similar type. In each unit a "fixed station" (the block in the unit which would be expected to have the greatest fly prevalence) was selected by the entomologist. A second block from each unit was selected at random. The fixed station was checked each week with the Scudder grill, and each week a different random station from each unit was also checked with the Scudder grill. Every block in each unit was examined weekly by the visual survey method. According to H. F. Schoof (unpublished data), similar results were obtained by all three methods in an area having a low sanitation level (fig. 1). In an area of better sanitation, results by the random-block grill survey and the visual survey were similar, but the fixed-block grill survey displayed peaks which were not reflected by the other two indexes.

The more flexible response of the fixed-block survey to extreme conditions is an advantage in some scientific investigations, but in routine control operations it suffers from the serious disadvantage that the fixed blocks may receive greater attention than the random blocks.

Many variables influence the behavior of flies. The time of day at which a count is made, temperature, amount of cloud cover, precipitation, and wind velocity can cause marked variation in grill counts. The resulting data may seem very difficult to appraise if attention is focused on these and other sources of variability. In the aggregate, however, the data provide adequate information on points of primary importance.

Epidemiological Field Study

In an early field study in Hidalgo County, Tex. (4), simple indexes were used to determine whether fly control in a poorly sanitized area would lower the incidence of diarrhea and enteritis. A group of small communities was divided into two sets. For a period of several months, April 1946 through August 1947, the flies were controlled in one group but not in the other. Control was accomplished by application of residual insecticide every 6 weeks, with spot re-treatment when necessary. At that time, development of resistance of flies to DDT

had not become a problem. In September 1947, fly control was discontinued in the first group of communities and begun in the second group. In each group a fixed set of blocks was examined for flies each week. The three highest grill counts in each block were recorded, and the highest reading was used as a statistic for comparison with data on diarrheal disease incidence collected from residents of the area.

Figure 3. Reported diarrheal disease in children under 10 years of age, 2-month moving average. Diarrheal disease control studies, Hidalgo County, Tex., 1946-48. (Redrawn from ref. 4.)

From these area residents, data on incidence of diarrhea was obtained through household visits by interviewers. The infection index chosen was the attack rate among children under 10 years old, and from this group monthly samples of stools were cultured for *Shigella* and *Salmonella*. A summary of results on fly prevalence and incidence of diarrhea in the treated and untreated communities is presented in figures 2 and 3. The many sources of variability in individual measurements apparently did not impede recognition of the main effects of the treatment.

Interpretation of Results

In some entomological surveys, there may be no comparable control population from which a random sample may be selected. This point may be illustrated by entomological appraisal of the effectiveness of treatment of households with residual insecticide during the final stages of malaria eradication in the United States. The counties selected for treatment were those which

in the past had had the highest malaria rates. In these counties, densely inhabited areas with the heaviest *A. quadrimaculatus* breeding potential were given preference for treatment. Hence, there was no comparable control area. Selection of individual comparable houses in the treated areas and in the adjoining untreated areas was left to the discretion of the entomologist.

The index chosen was a simple one—presence of live *A. quadrimaculatus* in a home during the afternoon. Movement of these anophelines during the daytime is negligible so that it could be assumed that any found in homes during the afternoon had entered not later than the preceding night. Because the residual insecticide was slow in action, no inspections were made during the morning hours.

In the course of 4 years of work, approximately 47,000 treated and 5,000 untreated houses were inspected (5); live *A. quadrimaculatus* were found in 1.7 percent of the treated and in 16.0 percent of the untreated houses.

The difference between the two percentages is manifestly significant by any statistical test. However, interpretation of the significance depends upon one's judgment of the ability of the entomologist to select comparable samples of treated and untreated houses. Although this is an extreme example, it is illustrative of the qualitative judgments which enter into most entomological sampling problems.

Results of entomological surveys are influenced by many variables which cannot be controlled and by many subjective factors not amenable to routine measurement. Statistics used to describe the findings should be simple and readily grasped by the epidemiologist, the entomologist, and the engineer. By using simple statistics, qualitative interpretations may be made jointly by the statistician and his colleagues in the natural sciences. Interpretation

of elaborate statistical methodology depends in many instances on the statistician's intuitive appraisal of the extent to which theoretical assumptions may be violated. On these questions the natural scientist usually has less basis for making judgments, and he may regard the methodology as an "ivory tower," and of questionable value. Therefore, the statistical presentation should be in terms of statistics whose import is fully understood by all members of the group.

Many phases of an entomological survey may give rise to special problems for which planned experiments of complex statistical design are necessary. Among these are tests of collecting devices, individual differences among collectors, and design of subsampling methods for rapid estimation of the composition of trap collections.

However, even in the planned entomological experiment, the intangibles of skill, effort, and thoroughness play a leading role, and the statistician must learn to reckon with these factors as familiarly as with the tools of his statistical methodology.

A Sample Survey of Home Injuries

By F. M. HEMPHILL, Ph.D.

On the basis of preliminary data from the continuing study of nonfatal home accidents in Washtenaw County, Mich., we can say, with some confidence, that:

1. There were, on the average, six home injuries per person during the year.

2. Females suffered approximately twice as many injuries as males.

3. The most frequent type of injury reported was "cuts," and the part of body most often injured was "fingers and hands."

4. Factors clearly important in planning programs of prevention of home accidents include: age of persons, time spent at home (exposure time), crowding, emotional and psychological states of persons, environmental factors, activity of person.

5. A preliminary study between "height-weight-age" and "rates of injuries" showed no clear association.

6. Injuries from falls, although relatively infrequent, appear important from the standpoint of severity in terms of "days lost," "costs" and "duration of injury."

7. Most nonfatal home injuries occurred in the kitchen. Most kitchen injuries were burns incurred during food preparation.

8. Forty to fifty percent of home injuries occur between 10 a. m. and 12 noon and between 4 and 6 p. m.

Dr. Hemphill is associate professor of public health statistics at the School of Public Health, University of Michigan. This paper was presented June 19 at the Second Conference on Public Health Statistics, School of Public Health of the University of Michigan, Ann Arbor.

The Washtenaw County Health Study

An investigation of the extent and causes of nonfatal accidental injuries occurring in the homes of Washtenaw County, Mich., as reported by householders, was conducted by the School of Public Health of the University of Michigan from February 1, 1951, to January 31, 1952. Funds were provided by the Division of Research Grants, Public Health Service.

The study did not purport to solve all problems of home accidents. Its primary purposes were to find the rate of accidental injury occurring within the homes of Washtenaw County from study of a segment of the population and to study selected factors—environmental, physical, and psychological—associated with injuries and injured persons. Many subsidiary phases of the study were contemplated, all of them dependent on fulfillment of the primary purposes.

Methods of study included interviews of responsible members of dwelling units by trained interviewers, the dwelling units being a probability sample of the dwelling units of the county, and a detailed appraisal of selected environmental factors found in a subsample of dwelling units selected from the original probability sample.

At the time this study was planned, reports of scientifically designed sampling studies of nonfatal accidental injuries incurred within homes were scarce, and lacking in essential criteria. Therefore, there were no estimates of expected rates for planning of optimum sample size and sampling procedures. Definitions were inadequate for research purposes. Acceptable questionnaires were not available. Codes for data were undeveloped. There were no interviewers

available who had experience in this field of inquiry. Data were inadequate for prediction of rates of refusal to be interviewed. These inadequacies were recognized before the investigation was proposed.

Furthermore, there was cognizance that success of such a study would be dependent on organized cooperative effort of several agencies and of the citizens of Washtenaw County. This study was a cooperative undertaking and not the result of individual research.

Interviewers comprised the largest and most important of the cooperative working groups. These citizens of Washtenaw County submitted to long hours of preparatory training in techniques of interviewing, adjusting themselves to rigid supervision, filling quotas of work, becoming skillful in gaining the confidence of respondents, avoiding dog bites, repairing tires and cars, explaining their activities to understanding police officers, and developing proficiency in other necessary techniques of experienced and confident interviewers.

All the consultation, action, supervision, and skills would have been in vain had there not been cooperation in the study by the selected respondents. Approximately 2,500 dwelling units were visited by the interviewers. Less than 4 percent of these calls resulted in no information. Outright refusals to give interviews were very rare. Each of the staff of the investigation will long remember and appreciate the gracious persons who gave freely of their time and registered interest in the success of the study. The extraordinarily high response rate bespeaks skill on the part of interviewers sincerely interested in their work. Moreover, such rates of response may indicate recognition of the problem of accidental injuries and genuine desire on the part of our citizens to avoid these unfortunate events. Approximately 1 percent of the citizens in the sample proved exceptions to the rule by refusing to be interviewed. Other losses were relegated to the inevitable "not at home," "illness," and "out of town" categories.

Several noteworthy observations were made regarding the conduct of sample surveys of home injuries. Other investigators might profitably consider the following:

1. The word "accident" has different meanings to different persons. The term may include torn dresses, runs in hosiery, loss of jewelry, and other unexpected events not associated with injury. The word "accident" was used rarely in this study.

2. The cost of interviewing persons about all "accidents" was prohibitive in both time and funds. Accordingly, the investigation was limited to "accidental injury to persons" while in their homes, that is, in their dwelling quarters and immediate yard, lawn, and garage (Census Bureau definition of dwelling unit).

3. Effort spent in training interviewers was highly profitable in quality of data elicited and in saving of field survey time.

4. Change of interviewers on "call backs" to persons refusing to answer questions on the first call often resulted in successful interviews. Other techniques were useful in gaining entry to the home and in getting data, but all involved courtesy, a pleasant attitude, and sincerity of purpose.

5. Persons have difficulty in recalling accidental injuries, even relatively severe injuries. There is great loss in recall of injury with the passage of time.

6. Reporting of information given to "open end" questions—those allowing complete freedom of response—brought forth disclosures loaded with valuable information. However, skillful probing and "funnel-type" questions—transitional questions, from the general to the specific—were useful in providing uniformity of opportunity to impart information, attitudes, and ideas.

7. Methods used in this investigation produced reliable results from sample to sample, in terms of rates of injuries.

8. Survey methods can be used as practical tools for determining rates of accidental injuries. These methods can be made economical in time and in costs.

Scope and Design of the Sample

Washtenaw County was the study area or universe. However, institutions, hotels, dormitories, and fraternity, sorority, and rooming houses with more than eight roomers were not included. The basic principle of the sample

design was that every dwelling unit within the universe had a known chance of being selected in the sample. The Survey Research Center of the University of Michigan advised stratified-area sampling methods (see diagram) to fulfill this aim and, on the basis of previous survey experience and a conservative estimate of expected rates of injury, also advised the preparation of a total sample of approximately 3,000 households—one-twelfth of the total dwelling units (36,000) of the universe.

This total sample was divided into six subsamples of approximately 500 dwellings each, from which interviews were to be collected over a 6-month period. The principal reasons for planning six subsamples were to study seasonal trends and characteristics of home injuries, to avoid any possible effect of repetitive interviewing on occupants of dwelling units, and to economize by training and administration of a small staff for 6 months rather than of a large staff for a shorter time.

Considering that the interviewing would require 6 months, it would be necessary to conduct interviews in 1 out of 72 of the dwelling units in the county each month. Since a minimum of 500 interviews was desired from each monthly subsample, an additional 10 percent of the dwelling units in the county were selected to allow for sampling losses and nonresponses. Monthly subsamples were therefore set at approximately 550 dwelling units each—a total sample of approximately 3,300. This represented about one-eleventh of the total, establishing a sampling interval of 1 in 66 dwelling units for each monthly subsample.

When the sampling error had been computed for the first two monthly subsamples, it was concluded that reliable estimates of incidence of home injuries could be established by fewer than the planned six monthly subsamples of 500 interviews each. Therefore, the sixth and last subsample was deleted from the proposed total sample. The desired size of the revised sample (5 subsamples) was 2,500 completed interviews, of which 2,453 interviews (98 percent) were obtained.

The chosen area sampling procedure produced a total of 311 sampling strata. These were outlined on maps after a detailed study of aerial photographs.

Stratified Sampling Terminology Washtenaw County Survey

1. **Dwelling unit (D. U.).** A group of rooms or a single room, occupied or intended for occupancy as separate living quarters by a family or other group of persons living together, or by a person living alone. A group of rooms occupied or intended for occupancy as separate living quarters is a dwelling unit if it has separate cooking equipment (1).

2. **Stratified sampling.** Classification of the universe into strata and the drawing of a sample from each stratum.

3. **Stratum.** A division of the universe (county) containing homogeneous counterparts. In this study, a stratum contained approximately 66 dwelling units, except in lake and rural areas, where the stratum size was about 132 units.

4. **Block.** A subdivision of a stratum, bounded by streets or other recognizable boundaries (1).

5. **Section number.** A number assigned to designate a prescribed number of dwelling units within a stratum. In this study, each number from 1 through 11 represented approximately 6 dwelling units. Therefore, a complete set of these numbers, from 1 through 11, inclusive, represented a stratum of about 66 dwelling units.

6. **Block listing.** The recording in consecutive order of the address or description of every dwelling unit within a sample block.

7. **Listing sheet.** The form on which block listing was recorded. This form contained a diagram of the block to be listed, showing the point at which the listing was to commence and proceed in a clockwise direction.

8. **Within-block-interval.** The interval between selected addresses on a block listing sheet. In this study the interval was 6 or a multiple of 6, and was determined by the number of section numbers contained in any one sample block. For example, if a block contained three section numbers, the within-block-interval number would be 3 times 6, or 18.

9. **Segment number.** The 20 townships of Washtenaw County were each designated by a segment number from 1 through 20. The segment numbers had no significance in the sampling procedure but facilitated the geographical grouping of interviewers' assignments and the computation of work and mileage records.

Strata-Block Designation

For this study, Washtenaw County's population was considered to be of six general population groups. As an aid in distinguishing the

general population types from which the various strata were drawn, the strata (and their representative blocks) were classified and numbered in distinct groups. This arrangement

provided efficiency in planning travel, in assigning interviews, and in other phases of the survey as well as allowing for rapid tabulation by population types, as follows:

**Example of two-stage stratified sample address selection
as applied in Washtenaw County survey**

The probability of selecting any dwelling unit in this stratum was $\frac{C_i}{11} \times \frac{1}{6 \times C_i} = \frac{1}{66}$ where $\frac{C_i}{11}$ was the probability for selecting the i^{th} block and $\frac{1}{6 \times C_i}$ was the probability

for selecting dwelling units within the i^{th} block. To determine which block represented the stratum, a number between 1 and 11, the range of section numbers, was selected from a table of random numbers. For example, if the number was 7, this would indicate that the block which contains section No. 7 was selected for sampling. In this sample, the selected block also contained section No. 8, thus C_i was equal to 2, the number of section numbers assigned to the i^{th} block.

In this example, the selected block was found to contain 15 dwelling units. Since this block had two section numbers, the within-block-interval to be used for selecting the addresses—total section numbers times 6 (2×6)—was 12. A systematic selection was then made from this block by first drawing a random number (not greater than the within-block-interval) between 1 and 12 to designate the first or starting address on the block listing sheet. In this case, the random number was 2, which designated the first address selected in the block. By adding the within-block-interval (12) to the first address (2), the second address was determined as number 14. These two selected addresses, therefore, represented stratum 5 for one subsample and were identified on the listing sheet for future use.

<i>Code</i>	<i>Areas</i>	<i>Population type</i>
1-102	Ann Arbor.....	Urban.
110-162	Fringe areas of and between Ann Arbor and Ypsilanti.....	Congested rural.
163-172	Pittsfield Village.....	Emergency housing.
201-270	Ypsilanti.....	Urban.
286-299	Willow Run Village.....	Emergency housing.
301-330	Small town: Chelsea, Dexter, Manchester, Milan, and Saline.....	Towns and villages.
401-408	Lake areas.....	Seasonal residence.
501-524	Open country or rural areas.....	Rural.

Listing

Block listing was done in March 1951 by the interviewers as part of their training by the Survey Research Center. One block from each of the 311 strata was listed at this time and used for the selection of the addresses for the first two subsamples. As residents of successive subsamples were interviewed, small blocks were depleted and new blocks were listed in Ann Arbor, Ypsilanti, and congested rural areas, and the small towns prior to interviewing the third and fifth subsamples.

Selection of the third and fourth subsample addresses required the listing of 202 new blocks from the 311 strata. These blocks were assigned "A" numbers to distinguish them from the original and subsequent block listings. The fifth subsample required the listing of 149 new blocks, which were assigned "B" numbers.

In the rural and lake areas, the "blocks" (clusters of D. U.'s) were depleted slowly. Therefore, in these areas, the same blocks were used throughout the five subsamples, as were the listings of Willow Run and Pittsfield Villages.

The listing of every dwelling unit in Willow Run Village and Pittsfield Village was practicable by the use of address-location maps of these developments furnished by their respective managements. These areas were treated as unblocked strata and, therefore, having been completely listed, were sampled systematically at an interval of 66 for the entire survey.

The listers were instructed to inquire at large dwelling structures to determine the number of dwelling units in the structure. When there was no response to the inquiry, it was necessary for the lister to use ingenuity to deduce the number of dwelling units within a structure. Counting mailboxes, doorbells, TV antennas, and meter boxes, and inquiring of mailmen, milkmen, and neighbors were useful methods in determining the number of dwelling units at one address or structure.

After the listing and selecting of dwelling units had been completed, identifying information was transcribed to questionnaires and to a registry kept in the survey office. This registry proved an efficient device to account for each questionnaire at all times.

Subsample for Environmental Appraisal

A subsample of dwelling units for environmental appraisal was drawn from the total sample subsequent to completion of the injury-interview phase of the study. Selection was designed to facilitate comparison of environmental findings between homes from which injuries had been reported and homes which had reported no injuries. Selection of the units, therefore, admitted approximately an equal number of "injury" and "noninjury" homes for the environmental study. Known probability of the selection of each dwelling unit in this subsample was preserved. Appraisal was completed at 263 of the 330 dwelling units selected for this study.

Household safety appraisal forms prior to this study dealt separately with specific environmental features, such as water systems and heating systems. Environmental survey schedules which allowed complete and systematic recording of appraisal items and conditions for each room were developed for this study by repeated field tests and subsequent revisions until their content, sequence of items, and format were realistic.

Results of the environmental appraisal will be available later. Findings to date indicate:

1. A larger percentage of refusals to cooperate may be expected in environmental appraisals than from injury interviews.
2. Training of personnel for environmental appraisal is essential.
3. The type of appraisal schedule developed in this study is far superior in arrangement to schedules previously used.

4. Concepts of sampling surveys should be employed in environmental appraisal for the sake of economy and time, and perhaps for accuracy of results.

5. Environmental hazards are important factors in causing accidents in homes.

The size of sample taken for appraisal in this study will produce a relatively large sampling error for most or all items of the schedule. However, as heretofore stated, the primary purpose of the substudy was to investigate differences between hazards found in homes from which accidents had been reported and homes which had not reported accidents.

Administrative Controls

Supervisory controls were established over interviewers, content of completed interview schedules, production rates of interviewers, and coders. Fiscal controls were established independent of supervisory controls.

Applications of interviewers were screened. Those selected were trained by lecture, demonstration, and supervised interviewing. All completed interview schedules were edited for completeness and quality of content before acceptance.

Coding of the data was begun subsequent to

acceptance of interviewers' records for the first two subsamples of the injury study. Controls over coding were evolved. Coders were trained, and their work checked for accuracy and completeness. Coded data were punched on IBM cards and checked for punching mistakes preparatory to tabulations.

Evaluating the Method of Study

In planning the investigation, certain criteria of consistency of findings from monthly sample to monthly sample were formulated for evaluation of methods used. Among the topics to be evaluated for consistency were male-female ratio of sample population, room-person ratio, and injury rates.

Male-to-female ratios for the five consecutive subsamples were 0.98, 0.98, 0.96, 0.94, 0.94, respectively. Variations of subsample ratios from the total-sample ratio were less than 2 percent. Room-person ratios varied by subsample from 1.6 to 1.7. Injury rates (table 1) were highly consistent from subsample to subsample, ranging from superficial injuries to females from 14 to 16 per 100 and males from 7 to 8 per 100; major injuries to females ranged from 57 to 62 per 1,000; to males, from 33 to 52 per 1,000.

Consistency of findings between subsamples

led to the following conclusions: The sampling methods and procedures used in the study were reliable; data of the study might be considered as one sample; and efficiency of the sample was satisfactory considering the estimates on which the design was based.

Examples of Findings

The illustrative findings here reported are subject to limitations of the methods used, the universe from which the sample was selected, and the interpretations applied to the data. Application of these findings to populations or environments which are distinctly different from those of Washtenaw County, Mich., in 1951 would be unwarranted.

Types of Injuries

Injuries which resulted in either: costs, lost time, kept from usual activity, or required treatment outside the home, were classified as "major" injuries. All other injuries were considered as "minor" or "superficial."

Superficial injuries were based on reported injuries sustained within 1 week prior to the date of interview. Major injuries were based on reported experiences within 1 year prior

to the interview date and occurring in the dwelling unit at which the interview was taken.

Injury Rates and Sites

Procedures used, definitions imposed, loss of recall with passage of time, and perhaps other restrictions led to the conclusion that injury rates as determined by this study were minimal.

Highly significant differences resulted between rates of the two sexes for both major and minor injuries (table 1). Rates of major injuries to females approximated 6 injuries per 100 females per year; to males, 4 per 100 per year. Rates of superficial injuries to females approximated 15 injuries per 100 per week; to males, 8 per 100 per week (see chart and table 1). Simple extension of rates for 1 week to that of 1 year indicates that each female may average eight superficial injuries per year while males may average four such injuries per year.

These higher rates of injuries to females were associated with greater number of hours spent in the home (see chart) and perhaps with occupational pursuits of housewifery.

Kitchens were the room-site of the greatest number of injuries (table 2). Actions in which

Comparison of crude and adjusted superficial injury rates, by age group and sex, for total sample.

the burns were incurred were predominantly other than handling of hot objects and materials. This finding indicates that programs to prevent burns in kitchens should aim largely at actions such as reaching over boiling pots and tea kettles, and avoiding splatter of hot fats, rather than concentrating on care in handling hot objects and materials. Preparation of food, cooking of food, disposal of remnants, and cleaning of dishes and utensils were practices often mentioned as resulting in major as well as superficial injuries. Cuts, burns, and bruises, were predominant types of injuries suffered in kitchens (table 3). Accidents attendant on use of knives and handling tin cans and broken glass were frequently associated with cuts and pierces. Accident prevention may well be directed to these areas. Unsafe ladders and kitchen stools, ill-advised uses of chairs and

boxes for reaching high storage places, improper storage, slippery floors, cluttered floors, and inadequate lighting were mentioned often in relation to falls and resultant bruises and fractures occurring in kitchens. References to unwise practices, states of distraction, hurry, worry, anger, excitement, and other emotional and psychological deviations were recognized in reports of many of these injuries.

These reported injuries occurring in kitchens are mentioned to demonstrate the types of complex studies now under way in attempts to specify points of attack in prevention. This much we can report with full confidence: "There's someone in the kitchen with Dinah." "Accident Hazard" is his name. His intentions are to cause bloodshed, to burn, to bruise, to break, to suffocate, to electrocute, and to poison. This villain is no respecter of sex. He

Table 3. Reported injuries in kitchen, by type of injury

Total.....	54	260	314	19	53	72	386

attacks strong, virile males with much success. His victims assist him, often seemingly encourage his attack by providing accident-inviting arrangements in the environment. Unplanned acts, unknowing acts, emotional and other psychological conditions contribute to the villain's success. Elder family members "plant" well-sharpened knives for themselves and others to discover. Yonths reciprocate by leaving tripping hazards and bruising barricades for elders and themselves.

Resultant injuries occur regularly in the population surveyed; the injury rate was remarkably constant. Many persons in the survey expressed the opinion that injuries in homes were inevitable, while others did not recall having any injuries at any time.

Findings from this study are for nonfatal injuries. There is considerable variance between implications from these data and from mortality data. For example, some studies show that the bedroom is the place of most accidental injuries resulting in death. This study shows that relatively few major and minor injuries were reported as having occurred in the bedroom. Other discrepancies with mortality data are discernible between reported findings from various sources. These variations should be evaluated in terms of definitions set forth in the respective studies. Many of the apparently differing findings from fatal and nonfatal home injuries may be complementary in their description of the total problem of accidental injuries incurred within homes.

Superficial-Major Injury Ratios

Findings from the Washtenaw County research indicate there is a stable ratio of super-

ficial to major injuries under the methods, definitions, and restrictions adopted for this study. If this relationship is accepted, certainly appraisal of the problem in local areas becomes economically feasible because of the high rates of superficial injuries. Importance of this implication should not be lightly considered. A practicable and economical plan for determining relative degree of the problem of accidental injuries occurring within homes has long been sought. Methods used in the Washtenaw research should be modified for application in local health jurisdictions. Experience gained in the study will be relayed to those wishing the information. Relatively small but well-designed sample surveys of dwelling units promise good returns in this field. Studies now in progress should produce further evidence on applicability of such an approach.

ACKNOWLEDGMENT

The following persons and organizations assisted in various phases of the study: Leonard Board and Frederick Kent, Public Health Service; Robert Patton, New York State Health Department; Dr. Otto Engelke, director, Washtenaw County Health Department, and his staff; other county agencies, such as the Planning Board, sheriff's office, and the police departments of Ann Arbor and Ypsilanti; and the following units of the University of Michigan: sociology, architecture, all departments of the Graduate School of Public Health, and the Survey Research Center.

Laboratory Control in Milk Sanitation

16 mm., sound, black and white, 9 minutes, 1951.

Audience: Sanitarians, sanitary engineers, laboratory workers in milk sanitation, and other personnel with education and experience in the field of public health milk sanitation.

Available: Loan—Communicable Disease Center, Public Health Service, Box 185, Chamblee, Ga. Purchase—Castle Film Division, United World Films, 1445 Park Avenue, New York 29, N. Y.

This film emphasizes that sanitary handling by producers and processors is essential to safe milk. Therefore, the sanitarian has the responsibility of working with producers in promoting the best sanitation practices on the farm and with processors to insure satisfactory handling of milk at the plant. He measures the efficiency of sanitation practices by data obtained through the collection and bacteriological testing of representative milk samples.

The film shows how the sanitarian collects samples of processed milk

from delivery trucks. These samples are examined by a competent bacteriologist in the laboratory, who uses standard methods approved by the American Public Health Association. The film shows the sanitarian using the results of these tests to aid processors in eliminating any sources of contamination in their plants.

The sanitarian is also responsible for the handling of raw milk at individual farms. The film shows the sanitarian collecting samples from cans of raw milk as they come from

the farms. During the sampling, the milk is checked for temperature and sediment. The samples are then taken to the laboratory for examination. The sanitarian reports any adverse findings to the farmers concerned and aids them in correcting the causative conditions.

Milk and Public Health

16 mm., sound, black and white, 11½ minutes, 1951.

Audience: Public health workers, public officials, and the general public.

Available: Loan—Communicable Disease Center, Public Health Service, Box 185, Chamblee, Ga. Purchase—Castle Film Division, United World Films, 1445 Park Avenue, New York 29, N. Y.

One of a series of films on sanitary milk production produced by the Communicable Disease Center, this is a general orientation film presenting the philosophy, nature, and effects of milk control legislation necessary to insure the safety of the milk supply to the consumer.

After developing the thesis that nature intended milk to go directly from the mother to the offspring with the least possible chance of contamination, the film depicts man's diversion of cow's milk from this direct producer-consumer path and its resulting tendency toward contamination due to insanitary handling.

As soon as laboratory tests revealed that haphazard milk production methods endangered the health of millions of people, especially children, milk control legislation had to be enacted. The film continues by showing the testing of herds by veterinarians, and the respective steps to be taken with cattle afflicted with mastitis, tuberculosis, or Bang's disease. It shows the scrubbing and cleaning of the dairies, the equipment, and the udders of the cows themselves. Progressively lower bacteria counts in the laboratory parallel the increasingly effective cleaning, refrigeration, and pasteurization employed by producer and processor. The film concludes with the thought that although most farmers have been educated to produce safe milk, and consumers to demand it, public health workers must strive diligently to eliminate any negligence, apathy, and ignorance which still exists.

Intrastate Evaluations of Syphilis Serology

By ALBERT V. HARDY, M.D.

At the request of the National Advisory Serology Council of the Public Health Service, a survey was conducted in 1951 to determine the current status of intrastate serology evaluations. The emphasis placed on the National Evaluation of State Serologic Laboratories since its initiation in 1937 has, to some extent, tended to obscure in the minds of public health workers the importance of State programs in this field. It is the purpose of this report to call attention to the activities of State laboratories in improving the quality of serology in their respective areas.

Information was collected by questionnaires addressed to directors of State and Territorial public health laboratories. Replies were received from the 48 States, from the Territories of Alaska, Hawaii, and Puerto Rico, and from the cities of New York and St. Louis. Forty of the 53 laboratories reporting had active intrastate serology evaluation programs involving the intrastate exchange of samples for examination. The extent and duration of these programs in 36 States, 2 Territories, and 2 cities are summarized in the table. The numbers of laboratories participating are given first, 4,200 in all—3,810 hospital, clinic, or private laboratories, 312 city, county, or regional laboratories, and 78 Federal laboratories.

The questionnaire called for a statement of the average, the minimum, and the maximum number of specimens submitted to each participating laboratory per year. Less than half of

the laboratories indicated that the number of specimens per laboratory varied; commonly, a fixed number was sent to each participant. Hence, if stated, the average number of specimens is given in the table. Ohio recorded the minimum only and Oregon the maximum, and these figures were used for those States. Oklahoma gave the maximum and the minimum numbers only and the latter are shown. The number of specimens distributed to each laboratory in that State varied from 10 to 240. Fourteen State laboratories submitted from 10 to 25 specimens to each local laboratory, 10 from 40 to 96, while 16 submitted 100 or more specimens.

The total numbers of specimens distributed in each area were computed from the information given. Over 200,000 specimens of blood or serum are prepared and distributed annually in the intrastate serology evaluation programs. Eight States distributed less than a total of 1,000 specimens each; 21, from 1,000 to 9,999; and 7, more than 10,000. The largest number of specimens (34,600) was distributed by Ohio, which sent a minimum of 200 to each of 173 participating laboratories.

The number of years during which the program has been in progress is given in the final column of the table. The program was initiated first in New York, Michigan, Connecticut, and California. An evaluation program has been in operation for 15 years or more in these States. In four States it has been in effect for less than 5 years.

Serum specimens only were distributed by 29 States, some blood and some serum specimens by 4, and blood only by 7 States.

The Venereal Disease Research Laboratory was used as the reference or control laboratory

Dr. Hardy is director of the Bureau of Laboratories, Florida State Board of Health. In 1951 he was chairman of the conference of State and Provincial health laboratory directors.

¹ Number of laboratories participating not stated.

² Exclusive of St. Louis.

³ Exclusive of New York City.

by 30 of the States, and in 12 it was the only reference laboratory. The State, Territorial, or city laboratory handling the program was the only reference laboratory in eight instances. Two States used as a control the average findings of the participating laboratories. Author-

serologists were used as a reference laboratory in four instances in States which used multiple laboratories in this capacity.

All of the 40 State laboratories "offer an educational program or consultive service to laboratories desiring or needing assistance."

Eight others which do not distribute specimens are prepared to aid in this manner. The educational approach differs. Some laboratories provide special training and experience individually or in small groups in the State laboratory; some aid by arranging group refresher courses, usually with the assistance of the Venereal Disease Research Laboratory, while others give emphasis to an annual visit of a serology consultant to each participating laboratory. Judging by the appended notes on the questionnaires, the intrastate serology programs are being increasingly recognized as an important educational activity.

Some of the laboratories having no intrastate evaluation program explained that they either lacked staff or had a limited need (as in States with few laboratories performing serology).

Massachusetts has a supplementary program for laboratories which perform tests on blood donors only. "There are 110 laboratories in this group and 30 specimens are sent to each during the year."

Specific information on methods used by the laboratories was not requested, but it was apparent that they use different methods to measure the reliability of performance. This is done in terms of specificity and sensitivity by some laboratories though, obviously, this procedure cannot be used by those submitting a small number of pooled serum specimens only. No information was obtained which could be used to assess the relative value of these varying programs.

The importance of the national serology evaluation is widely acclaimed, but participation is limited to the central public health laboratory of each State and Territory and to author-serologists. It is not generally appreciated that the intrastate evaluations are much more extensive. Many laboratories participate in these, and few local laboratories have serologists of wide experience on their staffs. For these reasons the intrastate serology programs have high importance in improving the quality of serology testing available to health officers, physicians, and patients.

Dr. Shannon Succeeds Dr. Topping

Dr. Norman H. Topping, associate director of the National Institutes of Health, Public Health Service, has been appointed vice president in charge of medical affairs of the University of Pennsylvania, effective November 1. Named by Surgeon General Leonard A. Scheele to succeed Dr. Topping is Dr. James A. Shannon.

Dr. Topping, a member of the commissioned corps of the Public Health Service since 1936, was assigned to research work at the National Institutes of Health in 1937. In 1946, he became assistant chief of its Division of Infectious Diseases, and in 1948, was named associate director, which carries the rank of Assistant Surgeon General. Dr. Topping is noted especially for the development of the first effective treatment for Rocky Mountain spotted fever. His research activities have included many studies of viral and rickettsial diseases.

For the past 31½ years, Dr. Shannon has served as associate director of the National Heart Institute, National Institutes of Health. He is recognized for his research in kidney function, chemotherapy, and malaria. He has served as guest investigator at the physiological laboratory at the University of Cambridge, England, and as a member of the staff of the Marine Biological Laboratory at Woods Hole, Mass. Before coming to the Public Health Service, Dr. Shannon was director of the Squibb Institute for Medical Research, New Brunswick, N. J.

Instructor's Guide . . .

Sanitary Food Service

"If the instructor has taught, the learner can perform." Based on this assumption, the Instructor's Guide has for its objective the training of food service personnel. It supersedes "Guide to Safe Service," published by the Public Health Service in February 1945. Because much has been learned since that time not only about food sanitation but also about how to put this knowledge into the "heads and hands" of those who prepare and serve foods, revision was a must. The U. S. Navy's Bureau of Medicine and Surgery, the Office of Education of the Federal Security Agency, and many consultants from the Army and the Air Force, other Federal agencies, State health departments, and educational institutions have aided the Division of Sanitation of the Public Health Service in preparing the guide.

Features of the book that make for convenience in use are: its mechanical binding, colored division sheets between parts, contrasting type, and pass-out sheets for distribution to the class. The format, type faces, and illustrations are all functional. Its size, 2-columned page, and the binding which allows it to lie flat in the hands of the instructor are designed for greater serviceableness. Directions and instructions appear in bold face; questions to ask the class, in italics. Regular type indicates the material that may be taught in any way the instructor desires. White on black illustrations are for blackboard use. Graphs and linecuts illustrate what the instructor is to do.

Samples of the pass-out sheets (enough for the class may be obtained from the Government Printing Office) and samples of certificates to be given members of the class upon the successful completion of the course are included.

Part I tells how to use the guide; part II, how to conduct the course. Part III, the course, is divided into eight "sessions." Each session spells out meticulously some vital fact of sanitary food service. And as it is recognized that we learn by doing, volunteer demonstrations are provided for and visual aid references are listed for nearly every session. Part IV is made of six appendixes: bibliography and references, optional material, visual aid utilization guides, techniques for discussion leaders, pointers in promoting and organizing food-service employee training programs, and demonstration techniques and sample display materials.

• • •

Sanitary Food Service. Instructor's Guide to be used for training food service personnel. (Public Health Service Publication No. 90) 1952. 316 pages; illustrated. 45 cents. (Also issued as NAVMED P-1333 by the Department of the Navy, and as AFM 146-7 by the Department of the Air Force.)

Aging . . . A Community Problem

Shortly after the National Conference on Aging, held in Washington, D. C., in 1950, the Federal Security Agency established a Committee on Aging and Geriatrics to act as a clearinghouse for all information relating to this field. This publication was prepared by the committee to help acquaint communities with the problem and to offer suggestions for its solution locally. The pamphlet discusses the aging problem in terms of the numbers of older persons, their economic and health needs, living arrangements, creative interests, and employment. How older people can be helped to live happier, healthier, and more active lives, and how their capacities can be used to strengthen the community and the Nation are also discussed. Community action, through the development of local citizens' committees, is urged, with emphasis on the fact that the burden of the effort in the solution of

the aging problem lies with local governments, private organizations, and the individual citizen.

Aging . . . A Community Problem. Federal Security Agency Committee on Aging and Geriatrics, Washington 25, D. C., 1952. 12 pages. Available without charge from the Committee on Aging and Geriatrics.

for the general public

Poison Ivy

Of particular importance during the summer months, this leaflet describes the poison ivy plant, the way in which the poison is spread from the plant, and the way it is spread from one part of the body to another. The characteristic symptoms, a burning and itching sensation followed by a rash and probably small or large blisters, are discussed. Instructions are given for the preparation and use of a treatment for mild cases. The reader is strongly advised to seek the help of a physician if there are large blisters or severe inflammation, or if the inflammation is on the face or genitals. Common sense precautions for avoiding poisoning and suggestions for the eradication of the plant are discussed.

• • •

Poison Ivy. Health Information Series, No. 65 (Public Health Service Publication No. 194). Revised 1952. 1-fold leaflet. 5 cents; \$1.25 per 100.

Publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication (including its Public Health Service publication number). Single copies of most Public Health Service publications can be obtained without charge from the Public Inquiries Branch, Public Health Service, Washington 25, D. C.

Public Health Service

Research Grants and Fellowships

—Approved during June 1952—

On the following pages, *Public Health Reports* publishes the list of research grants recommended by the National Advisory Councils of the Public Health Service and approved by the Surgeon General. Fellowship awards are also included. Announcements of grants and fellowships are published after each of the three meetings held annually by the National Advisory Councils. The present listing represents actions of the June 1952 sessions which were still in effect on August 15. Withdrawals or other changes since that date have not been taken into account. The National Advisory Councils are made up of outstanding citizens skilled in the medical sciences, education, and public affairs. The Surgeon General may award only those grants recommended by the councils.

The lists of research grants and fellowship awards approved in February 1952, along with a statement describing the program, were published in the June issue of *Public Health Reports*, pp. 596-606.

Grants and fellowships have been grouped together by State, city, and institution. The source of funds for each grant is indicated by initial letters following each entry. The key to these abbreviations appears in the accompanying box.

The subject matter of the individual studies listed here is necessarily described in abbreviated form. The descriptive titles serve only to identify the general field in which the investigator will work.

Fellowships, designated by an asterisk, are identified after each name as follows:

(PB) predoctorate, bachelor	(PD) postdoctorate
(PM) predoctorate, master	(SP) special

Requests for application blanks or for further information concerning the research grant and fellowship programs should be addressed to the Division of Research Grants, National Institutes of Health, Public Health Service, Bethesda 14, Md.

Public Health and Clinical Laboratories

in the

Diagnosis of Enteric Bacterial Infections

By ELBERTON J. TIFFANY, M.D.

Remarkable progress has been made in the prevention and treatment of many infectious diseases, but very few, if any, have been completely eradicated. The classical acute bacterial infections of the intestinal tract still occur with sufficient frequency to be of concern to the physician in practice and in public health work, and the syndrome of acute infectious diarrhea of the newborn from time to time complicates the management of hospital nurseries. Although in the past 20 years reported cases of typhoid and paratyphoid fever in this country have decreased from 23,000 to approximately 4,100 per year (1), the annual incidence of reported bacillary dysentery in the past 10 years has increased from 19,000 to approximately 28,000. These figures do not include the instances of diarrhea of unspecified cause nor those cases of specific infection which are not on record because they were not reported.

This discussion is concerned largely with the role of the laboratory in the diagnosis of the *Salmonella* and *Shigella* infections of man. The salmonellae include the true typhoid and paratyphoid organisms of human origin which give

rise to the classical enteric fevers, as well as more than 200 different identifiable serologic types which may be pathogenic for man in sporadic cases or outbreaks of acute enteritis but the reservoir of which is in the lower animals. The dysentery bacilli—the shigellae—are now recognized by the International Shigella Commission as constituting four major groups of a total of 30 types. (These are the organisms of acute bacillary dysentery and are practically always of human origin.) The *alkalescens-dispar* organisms are now accepted as constituting a special group, more closely related to *Escherichia* than to *Shigella* but still of interest in enteric bacterial infections.

Why Identification?

Our concern with the laboratory diagnosis of these infections arises from three considerations:

1. The nature and cause of an enteric infection cannot be determined with certainty without the assistance of appropriate laboratory tests. Typhoid or paratyphoid fever, the "food poisoning" type of *Salmonella* infection, and amebic and bacillary dysentery may frequently be suspected with a fair degree of accuracy on the basis of history, epidemiology, and clinical aspects, but the borderline or atypical cases are frequent enough to make accurate diagnosis impossible without laboratory confirmation.

2. Identification of the causative organism

Dr. Tiffany, officer in charge of laboratory consultation services of the Communicable Disease Center, Public Health Service, presented this paper at the twenty-first annual meeting of the Southern Branch of the American Public Health Association, Baltimore, Md., April 17, 1952.

should prove of assistance in the rational therapy of enteric infections in view of the reported favorable results with certain of the broad-spectrum antibiotics, particularly in the treatment of the systemic *Salmonella* infections (2-5) and of bacillary dysentery (6, 7).

3. It is important to know the source of the infection and to judge the likelihood that the case may in turn infect others. Is the organism of human origin, as for example the typhoid bacillus, perhaps derived from a permanent carrier, or does it belong to a group, such as *Salmonella typhimurium* or *Salmonella anatum*, commonly derived from an animal reservoir or a temporary human carrier? In the United States many *Salmonella* infections in the human are traceable to poultry and swine and to food products derived from them (8). *Shigella* infections, on the other hand, as well as true typhoid fever, are always of human origin. The epidemiology of a case must be understood if the spread is to be limited and recurrence prevented. This knowledge is incomplete unless the causative organism is known. The control problem is one thing if the infecting organism is proved to be the typhoid bacillus with its tendency to cause prolonged illness, to spread from person to person, and to give rise to the permanent carrier state. The problem is quite different if the organism is *S. typhimurium* or some other *Salmonella* of animal origin, with the likelihood of single accidental exposure and less probability of person-to-person transmission.

The laboratory procedures essential to the final identification of the salmonellae and shigellae have been well defined and are well known to the bacteriologists engaged in this work. Final critical identification of an organism may, however, be time-consuming and require materials and skills not available in the majority of laboratories. The time which is often necessary to accomplish complete identification and the consequent delayed report, sometimes couched in terms of antigenic factors and details with which the physician is unfamiliar, have caused some dissatisfaction and have led to the opinion that laboratory diagnosis of these organisms is largely academic. Fortunately, much information of value to the physician and public health worker may be on hand within a

few days. Studies are now under way which for some of these organisms may shorten the diagnostic interval to hours. Within the last several years a number of workers (9-11) have defined the simplified procedures which make possible within a relatively short time the classification of the majority of organisms encountered as to the *Salmonella* or *Shigella* genus, the major group within the genus, and in many instances the complete specific identification of the pathogens most commonly seen, leaving only the infrequent problem cases for the reference laboratory.

Degree of Identification Suggested

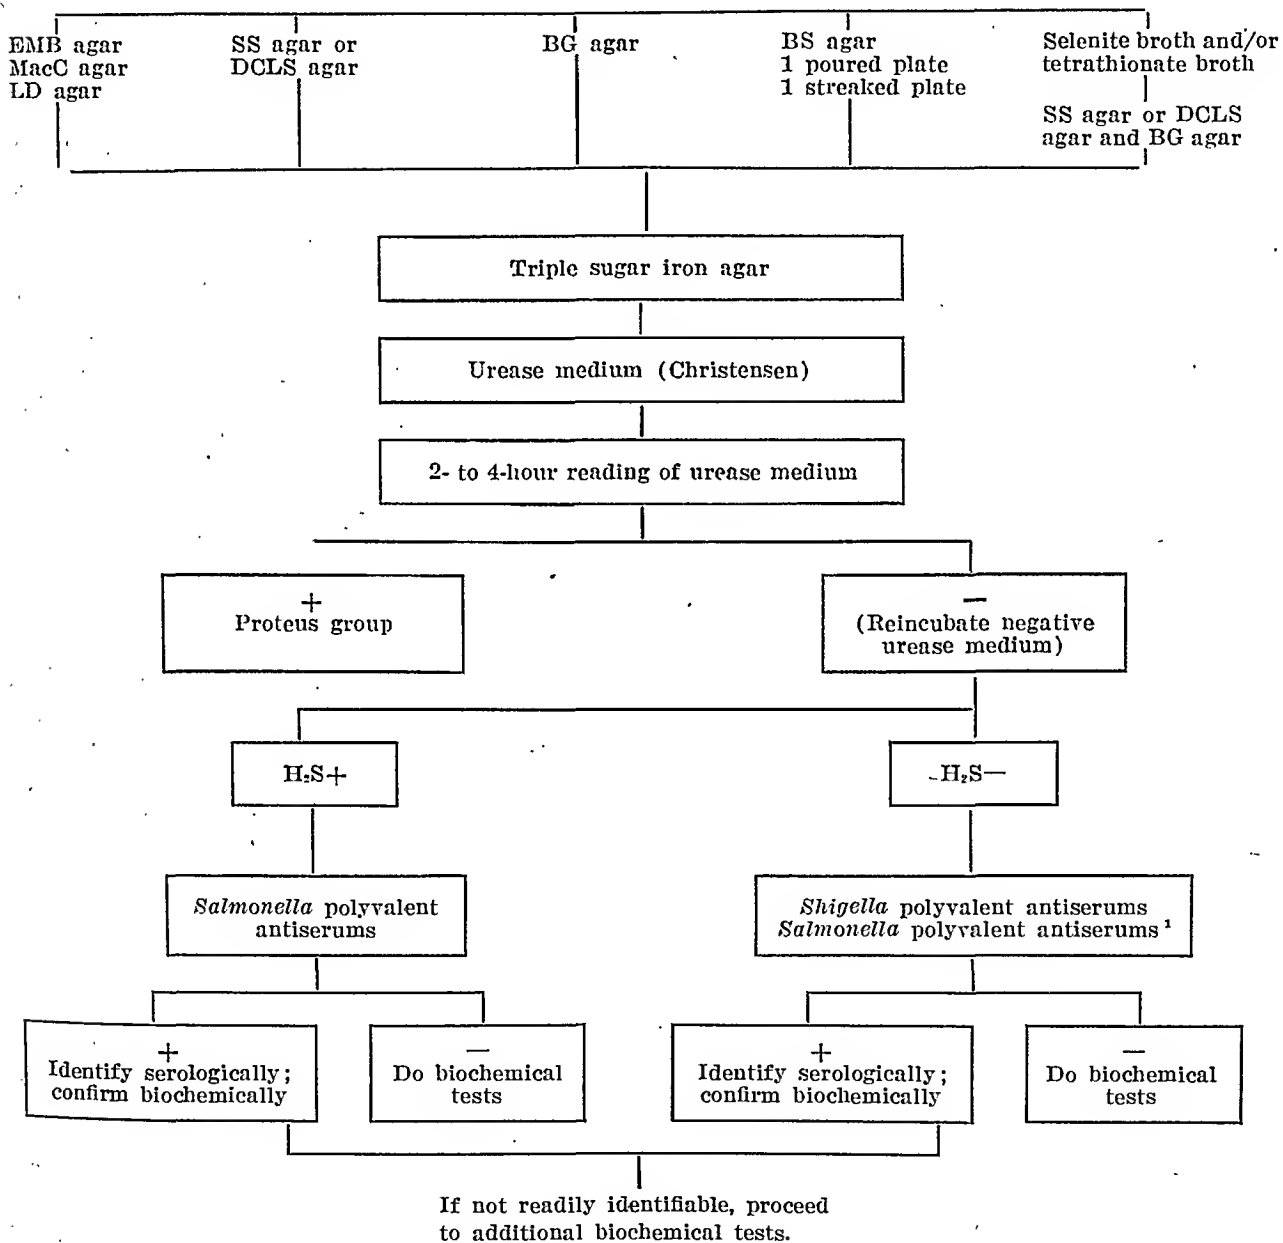

The degree of identification that may best be attempted by the various laboratories under consideration will depend mainly on need, facilities, experience, and type of laboratory. The several stages of procedure essential to complete identification of these enteric organisms are given in table 1, adapted from Edwards and Ewing (11). The salient features of procedure are further condensed in table 2.

The arrangement in table 2 suggests that the procedures themselves may logically fall into four stages of ascending complexity appropriate to different laboratories. It is not possible to be arbitrary about how much of the outlined procedure should be attempted by the various clinical and public health laboratories. The completeness of the service offered in any instance will depend on several factors such as demand, location and size of the laboratory, accessibility of possible reference laboratories, availability of reagents and, above all, upon the experience and interest of the laboratory staff. The interests of the two categories of laboratory are also somewhat different. The clinical laboratory will be expected to determine as early as possible whether the organism is a *Salmonella* or a *Shigella* in order that specific therapy may be more accurately focused. The public health laboratory will be concerned with more detailed information as to group and type of organism for the purpose of control and prevention of spread. However, both the practicing physician and the health officer will want, in the end, the same kind of information—full identification of the infecting organism.

The clinical or hospital laboratory which is equipped and staffed to do even a modest amount of cultural bacteriology could very well provide an effective screening service by carrying the procedure through the first four stages of enrichment, primary and secondary plating,

isolation to TSI slants, and exclusion of the troublesome *Proteus* organisms by the routine use of urease medium. Organisms which on TSI slants give reactions consistent with salmonellae or shigellae and which produce no alkaline reaction on the urease medium are

Table 1. Outline of procedure for identification of *Salmonella* and *Shigella* cultures
Fecal Sample

¹ Occasional *Salmonella* cultures may fail to produce hydrogen sulfide in TSI agar. Also certain salmonellae and shigellae cross agglutinate. *Salmonella typhi* and *Salmonella gallinarum* are anaerogenic. Rarely, anaerogenic cultures of other types appear.

Table 2. Condensed summary of procedure for *Salmonella* and *Shigella* identification

1. The specimen:
 - (a) Crude for immediate examination.
 - (b) Preserved, buffered glycerol saline for transport.
2. Enrichment and primary plating media.
3. TSI slants (also give information on H₂S).
4. Urease media (allow detection and discard of *Proteus*).
5. Polyvalent *Salmonella* antiserum.
Polyvalent *Shigella* antiserum.
6. Preliminary biochemical tests (consistent with the genus): glucose, lactose, sucrose, mannitol, salicin, adonitol, citrate, MR, VP, indol, motility.
7. Group determination:
 - Salmonella* (6 group serums):
A, B, C₁, C₂, D, E.
Also Vi serum.
 - Shigella* (5 group serums):
A, B, C, D (dysenteriae or Shiga, flexneri, boydii, sonnei, alkalescens-dispar,¹ respectively).
8. Simplified typing which will identify *S. typhi*, *Salmonella paratyphi A*, *Salmonella paratyphi B*, *Salmonella paratyphi C*, *S. choleraesuis*, and *S. typhimurium*.
H factor serums a, b, c, d, i, and 1,2 and 1,5.
9. Complete critical typing, with complete biochemical study where necessary.
10. Requires:
 - (a) A complete set of O and H factor serums for salmonellae.
 - (b) A complete set of group and type specific antisera for the shigellae.
 - (c) A staff experienced in the work.

¹ Alkalescens-dispar is included here although not now actually considered to belong to the *Shigella* group.

definitely open to suspicion as pathogens and merit further study. It is quite possible that this laboratory also might make its screening procedure more effective by performing the 11 simple biochemical tests indicated, which would further serve to exclude some organisms from consideration. Simple serology with commercially available antisera might also be done. Unless the clinical laboratory in question happens to be one of the relatively few which are in a position to carry the examination further, the suspected isolate must at this point be referred to another laboratory—usually a public health laboratory.

The public health laboratory, whether at the city, county, or State level, as well as the large hospital laboratory, should be able to accept either the referred isolate described, or the primary specimen in transport solution, and carry it through procedures 6 and 7—group determination and even type recognition of the

more commonly encountered forms. For the shigellae, this involves the biochemical and serologic procedures necessary to identify the organism as a dysentery bacillus and to place it in the dysenteriae, flexneri, boydii, sonnei, or alkalescens-dispar groups, and requires five serums. For the salmonellae, it is necessary to determine that the organism is indeed consistent with a member of the *Salmonella* group and to ascertain whether it is one of the species commonly of human origin, or whether it falls among the far greater number which are commonly derived from animals. Even these animal strains may often give rise to the temporary carrier state in man, whence they may for a time be the source of secondary cases.

Simplified Serologic Kits

This information in regard to the salmonellae can very largely be obtained by use of a simplified typing kit consisting of the six O factor serums A, B, C₁, C₂, D, and E; the five phase one H factors a, b, c, d, i, and the phase two H factors 1,2 and 1,5. The somatic Vi antiserum is, of course, also essential. Group A consists only of *Salmonella paratyphi A* and is rarely encountered in the United States. Most cases of *paratyphi A* infection seen here have usually originated in Mexico. In view of increased international travel today, however, it is perhaps well to include the serums necessary for the identification of this human pathogen.

Proper use of this simplified typing kit, plus the Kauffman-White schema, supplemented by appropriate use of a few biochemical tests, will allow the laboratory to identify *S. typhi*, *S. paratyphi A*, *Salmonella paratyphi B*, *Salmonella paratyphi C*, *Salmonella choleraesuis*, and *S. typhimurium*. In other words, proper use of such a kit will serve to identify, at least as to group, 98 percent of the *Salmonella* species pathogenic for man and likely to be encountered in the United States.

The biochemical tests and materials useful for the salmonellae are the same as those required for the shigellae. The four *Shigella* groupings serums and the alkalescens-dispar group serum suffice to give most of the information needed concerning a suspected dysentery bacillus.

For diagnostic work with the salmonellae and shigellae to be of value, the laboratory staff concerned must understand the properties of these organisms and their serologic relationships as set forth in the Kauffman-White schema and in the classification for shigellae proposed by the International Shigella Commission (11). Appropriate group and type specific factor serums must be available. Simplified serologic kits for the salmonellae and shigellae have been provided by the enteric bacteriology laboratory of the Communicable Disease Center to State health department laboratories desiring them. Appropriate serums for the simplified typing of the salmonellae and shigellae are now available commercially.

Certainly, every State public health laboratory should be able to provide the service so far outlined in identification of the salmonellae and shigellae. Private and public health city or county laboratories may also offer this degree of service. Excellent service in the laboratory diagnosis of enteric bacterial infections has been available for a long time in many hospital and city and county laboratories. The determining factors are demand, the availability of the necessary diagnostic factor serums, and an experienced staff.

Work for the Reference Laboratory

In order to perform the final and complete critical typing of all *Salmonella* and *Shigella* strains which may be encountered, it is necessary to have on hand a much larger number of the O and H factor *Salmonella* serums as well as the necessary grouping and typing serums for the shigellae. When a new, unusual, or atypical organism is involved, final identification may be time-consuming and may require several weeks of attention from a staff thoroughly versed in all the vagaries of enteric bacteria. Studies requiring this degree of detail can only rarely be carried out routinely by the local laboratory and are the special province of the reference laboratory.

There are several well-known laboratories in this country which are equipped to undertake complete identification of the *Salmonella* organisms and which are associated with State or city health departments, a few hospitals, or

the Public Health Service. Whatever their organizational position, these reference laboratories have certain features in common—they are staffed by individuals who have long experience with these organisms and who for the most part make their own serums.

The serologic relationships of the *Shigella* organisms have only recently been more clearly defined, and complete serologic analysis has not been as widely practiced on this genus. The good hospital or public health laboratory should be able, however, to isolate the organisms and identify them as to group. For complete typing, the shigellae may also be sent to the several appropriate reference laboratories in this country.

Anyone attempting to work in the laboratory with these enteric organisms will soon encounter the paracolon bacteria and will find them troublesome. The paracolon bacteria comprise a considerable spectrum of organisms falling into numerous subgroups with relationships ramifying among the salmonellae, the shigellae, and the colon bacilli. Although generally nonpathogenic and of nuisance value only in laboratory diagnosis, some strains may cause serious illness in man. They cannot therefore, always be disregarded. Much work remains to be done with the paracolon bacteria; there is at present no royal road to their recognition and exclusion. They are, in general, slow lactose fermenters and may give a delayed urease test only faintly positive after 48 hours of incubation. It seems inevitable that any system of screening enteric pathogens, as suggested here, will catch many paracolons in the net. The true identity of these organisms will have to await study by the reference laboratory whose staff can cope with the vagaries of the group.

Type identification of typhoid bacilli by means of bacteriophage is an important tool in epidemiology. But phage typing of the typhoid bacillus and of *S. paratyphi B* is a highly specialized procedure requiring care in the preparation and maintenance of the parent strains of bacteria and phages, and special training on the part of the staff. In view of these considerations and the low incidence today of typhoid fever, it has been considered preferable that specimens for this work be referred to one of the

14 special bacteriophage typing centers established in the United States (12).

Pathogenic Types of *Escherichia coli*

In the diagnosis of enteric bacterial infections a new field of considerable interest has been opened within the past few years. There is now evidence that at least certain identifiable strains of colon bacilli may be capable of causing primary enteritis.

Kauffman (13) in 1944 and in 1947 (14) published the results of his studies on the *Escherichia coli* group to which he had applied those techniques of antigenic analysis which have proved so valuable with the salmonellae. He also suggested "as a working hypothesis" that a number of the *E. coli* groups serologically identifiable by these techniques would prove of importance in certain of the infectious diseases of man. Approximately 125 O groups of colon bacilli have now been defined. Members of two of these groups have been isolated from cases of infections diarrhea of infants, and also, on occasion, from enteritis in the adult, under circumstances which indicate a causal relationship. These two types are 055-B5 and 0111-B4, and may be identified by simple slide and tube agglutinations using appropriate serums. It would appear that at least every major public health laboratory should have on hand these serums and should be familiar with their proper diagnostic use in cases of enteritis from which the more common pathogens seem to be absent. Other serologically distinct coli types may be shown to be related to human disease.

Rogers and associates (15) in England in 1949 suggested the value of chloramphenicol on the basis of their experience with a small series of cases of enteritis in children apparently caused by a serologic variety of *E. coli*. Smith and his associates (16) in 1950 reported encouraging results with chloramphenicol in the treatment of cases of infection with coli type 055. Only this year a hospital outbreak of infantile diarrhea has been reported by Modica, Ferguson, and Ducey (17) in which *E. coli* 0111-B4 was isolated from 45 cases. Chloramphenicol, aureomycin, and terramycin appeared effective in treatment. If this experience with chloram-

phenicol and other antibiotics is borne out, it is possible that the larger hospital laboratories may likewise find use for these diagnostic serums.

Recommendations

1. Every State public health laboratory and the larger local public health laboratories should be equipped to isolate *Salmonella* and *Shigella* organisms from the primary specimen, to identify them as belonging in all probability to the *Salmonella* or to the *Shigella* genus, and to carry them through group identification.

Laboratories of this caliber should also be able to identify specifically the typhoid bacillus, *S. paratyphi B* and *C*, as well as the more common salmonellae of animal origin, such as *S. typhimurium*, *S. choleraesuis*, and a few others which may by experience have been found common and important in a given locality.

2. The local hospital, clinic, or smaller public health laboratory may either refer its specimens directly to the nearest laboratory equipped to handle them throughout, or may process the specimens to the point of detecting suspicious organisms and of determining that these are at least not *Proteus* or *Pseudomonas*.

These smaller laboratories might even find it practicable to apply the simpler biochemical tests indicating that the organism in question is consistent with a *Salmonella* or *Shigella*. The suspicious organism should then be referred to the appropriate laboratory.

3. Complete critical typing is the function of the larger and specialized reference laboratory which may, depending upon circumstances, be functioning at the local, State, or national level.

One last comment, somewhat in the nature of a plea, appears appropriate. The bacteriologists who examine and study these specimens in the laboratory will be eternally grateful to the physicians who submit the specimens if they will send in at the same time a brief summary of the outstanding facts pertaining to the case: animal or human origin; case or suspected carrier; age and occupation; acute or insidious onset; duration of illness; probable exposure; possible food source. Many of the bacteriolo-

gists engaged in this work are deeply interested in the clinical and epidemiological data enumerated above. Without this information their own horizon is narrowed and their usefulness in the matter of communicable disease control is impaired.

NOTE: The Communicable Disease Center does not wish to duplicate services which are available locally. The CDC laboratory branch, therefore, accepts specimens for study only when submitted through a State health department laboratory (18).

State and Territorial Health Officers' Conference

The 1952 Annual Conference of the Surgeon General of the Public Health Service and Chief of the Children's Bureau with State and Territorial health officers, mental health authorities, and representatives of State hospital survey and construction agencies will be held from December 8 through December 11. Open sessions will be held in the auditorium of the Federal Security Building, Washington, D. C., on December 9 and December 11, beginning at 9:30 a. m. The remainder of the conference will be devoted to executive sessions and committee meetings.

Meeting the Health Needs of the Child

By HAROLD C. STUART, M.D.

No one would have the temerity to advise how to meet all the health needs of children at all ages. I could not cover fully even the needs of the newborn; hence I will not attempt to cover any specific need or age period. I propose, rather, to present certain guiding principles which, it seems to me, must be followed reasonably well if the modern objectives of child health services are to be accomplished. I will also suggest how our present services should be altered to incorporate these principles.

Most of the principles are quite obvious; they follow logically from well-known features of child development and related health needs. Unfortunately, too little attention is given to these principles in planning health services for children and still less in their day-to-day application.

Guiding Principles

Although the needs of a growing child are constantly changing, there are certain characteristics or features of these needs which are common to all ages. I propose to describe a few of these features and then to state the guiding principle for child health services derived from each. Some of these principles are closely related but each deserves separate consideration.

Integration

Health needs for the most part are closely interrelated and interdependent. They cannot

Dr. Stuart is professor of maternal and child health, Harvard University School of Public Health. He presented this paper at the forty-eighth Annual Health Conference, Lake Placid, N. Y., June 5, 1952.

be dealt with independently of the setting in which they exist or individually without consideration of other needs.

Of course, children can be given diphtheria toxoid, for example, and thereby have one health need met without any consideration of the setting or of other health needs, but most of the things we try to do cannot be handled this way. It is unwise, for instance, to prescribe feedings for infants in specific detail without considering the infant's size, rate of growth, activity, relationship with his mother, emotional responses to his care, and other complex situations.

A common fault of the well-child conference is that it isolates a few health needs of the infant, concentrates upon them, and deals with them didactically while ignoring importantly related subjects. The opportunities for this approach are limited.

Insofar as possible, then, the health needs of an individual should be considered as a whole, by the same person or, preferably, by persons working closely together as a team. The latter method permits broader scope and the use of several approaches but still offers an integrated program.

Flexibility

Health problems and needs of all children are constantly changing. Though certain basic needs exist throughout infancy, childhood, and adolescence, even these change quantitatively, qualitatively, and in the manner in which they may be met. They tend to change very rapidly during periods of rapid growth and physiological development—most rapidly in early infancy, progressively more slowly during childhood, and again rapidly during the unstable period of adolescence.

Therefore, health services must be flexible; they must be adaptable to the unusual as well as the characteristic needs of each group. The service must grow with the children it serves. This is particularly true of the family physician or pediatrician. The well-child conference often fails to serve the preschool child satisfactorily because it is geared to the needs of infants and is not readily adaptable to the more complex needs of the older age group.

Continuity

The total health needs of a child at one age are determined to a considerable extent by past experiences. They, in turn, influence future problems and needs. Of course, many problems are transitory, but others, particularly emotional needs—such as the infant's need for affection and security—have long-time significance.

A poor mother-child relationship may produce different kinds of behavior problems and have different effects upon feeding and nutrition at succeeding ages. Although under favorable circumstances these problems tend to resolve themselves, a disturbing relationship continuing for a long time is likely to have lasting effects upon the personality and the emotions of the child and be reflected in his dietary and other habits.

In view of these circumstances, continuity of services and a periodic follow-up are essential if the factors contributing to a child's health problems are to be appreciated. Periodic visits for health services permit a long-time view of a child's health and progress.

Individual Differences

Because of the great differences between children in all attributes, their health needs necessarily differ greatly. Although there are common characteristics of the health needs of all children at each stage of development, the needs of each child differ in their timing, their urgency, and the ways in which they may be met successfully. They differ also in their combinations and in the manifestations of their neglect. Individual differences derive mainly from constitutional factors, but also from environmental factors.

There is much evidence that children succeed

as well as they do in accomplishing their objectives in growth and development because of their inherent capacity to adapt to and make up for difficulties. The evidence is clear, however, that the potential for growth progress and for adaptation varies widely among individuals, as do all other attributes.

Only by knowing a child's basic characteristics, his environment, and his responses to his environment can one give the best counsel as to meeting his needs. Hence, to be most effective, health services for the child must provide for continuing study of him as an individual and of his environment. A continuing and reasonably broad health history and repeated evaluations of the child's status and progress and of the adaptations which he is making are essential. Thus, continuity of services means more than a loose connection between episodic services at succeeding ages. It implies, rather, periodicity appropriate for age with continuity in procedures and records.

For example, repeated evidence as to a child's leanness or fatness and his consistency or change in body build throughout the years is essential for proper interpretation of his weight. In most of our schools, weights and heights are taken and recorded periodically, but in relatively few instances is this information utilized to provide an adequate understanding of each child from the standpoint of his build, his habits, and the problems with which he may be faced for life in attempting to maintain proper weight.

Rapport

Health services can be made effective only by influencing the mother during the child's early life and by influencing the child directly more and more as he grows older and acquires independence. During adolescence, it is the direct influence upon the boy or girl which is most effective. Health services, however, must often be mediated through the personnel of the school and at times through a variety of community contacts. When several people are involved in giving instruction and guidance, good teamwork is required to assure consistency.

Derived from this feature is the principle that the health needs of the child can be met effectively only by establishing rapport with

him and with those who care for him. Some needs, of course, can be met through general services operating in the community or through services dealing with children collectively. Health protection and promotion as we view them today require, in addition, individual services brought directly to each child and his family at home, at school, in the doctor's office, or at health centers. Those giving the services must understand their respective roles and regularly take counsel together.

Related to Medical Care

The needs of the child in health are closely related to his illness experiences. Meeting health needs adequately is, in fact, the cornerstone of preventive medicine. Although health services and diagnostic-therapeutic services differ to some extent in objectives and in methods—for example, diagnostic-therapeutic services are more episodic in character, more difficult to organize and to provide in a standard way, and often require more facilities and professional workers than health services—it is frequently difficult to draw a sharp line between them. Furthermore, the health service personnel who know the child and family and have their confidence can be of immeasurable assistance in difficult situations arising during illness.

Hence, health services and medical care for children should be as closely related as circumstances permit. They may be provided effectively by the same person or by different persons, but in the latter case it is imperative that communication between all concerned with a given child be provided and utilized. In practice, the most elementary point of such integration of services is commonly neglected; the person responsible for one service to a child often does not even know who provides the other.

Principles Into Practice

If our present facilities are to provide effective health services for the child, these broad principles must be put into practice. I should like to suggest improvements which the various facilities can make toward the accomplishment of this goal.

General Practitioner

Ideally, the general practitioner should take a prominent part in providing health services for children. The part he plays can vary all the way from providing comprehensive care in health and in illness to providing only diagnostic and therapeutic services.

In the former situation, there are the problems of stimulating the physician's interest in health services, of his obtaining the necessary knowledge and understanding of the scope of health services as currently conceived, and of educating him as to the community resources which he can utilize for the benefit of children. There is also the ever-present problem of his giving the time required to do this work well.

When the general practitioner provides only medical care in illness, a known and accepted relationship should exist between him and some cooperating individual or organization which provides the health services. Many difficulties have been encountered in attempting to establish this type of relationship, particularly in large urban areas. There should be continuing efforts to improve understanding between general practitioners and physicians and nurses in child health conferences or other health services, by personal contact.

Prenatal Clinic

It is obvious that the health needs of the fetus are related to the health and nutrition of the mother and that an important function of the physician is the prevention of congenital disease or damage from improper intra-uterine environment or from traumatizing labor or delivery. One of the present problems is to broaden the vision of obstetricians and others giving maternal care to encompass the social, psychological, and educational factors affecting the course and outcome of pregnancy. More consideration needs to be given to the part played by the husband in family planning and to his preparation for effective parenthood. Both parents should be given more training in infant care and more help in psychological and social adjustments in anticipation of the birth of the baby. To add these services to present prenatal care programs requires not only more time and interest on the part of the physician

and nurse but also greater participation by auxiliary personnel on the maternal health service team.

Child Health Conference

The same general considerations apply to the infant and preschool child health conference as to the prenatal clinic, but the child health conference is further advanced in the practice of the principles of child health services. The objectives of the physician and nurse providing well-child conference service today are very different from those of only a few years ago. The primary objective is to build up the mother's competence by giving her the knowledge and attitudes necessary for successful child care and rearing, and by helping her to understand her own child and his particular needs.

The mother should be encouraged to study her own child and to share her observations, problems, and plans with the physician and nurse. She should come for counsel and not merely for instruction. She should be encouraged to consider the long view, to plan for the future. Most of these opportunities are lost when service is terminated at 1 year. Mothers thus oriented early will usually demand continuing or periodic health visits during the preschool years.

Dr. Martha Eliot of the Children's Bureau has recently pointed out that the child health conference today is directed toward helping parents with normal, everyday problems in the growth and development of their children. She has raised the question, however, as to whether the child health conference needs re-vamping to serve as an effective tool for this purpose.

Preschool and School Health Services

The nursery school and the day-care center should be more intensively utilized for the study and training of the child. This will be most

effective if done in cooperation not only with the mother and the home, but also with the physician or health conference personnel.

After the child enters school, teamwork becomes vastly more important yet more difficult because so many people have a part in his care and education. There must be close understanding between the home and the school, between the school health service and the family physician, and between the educational staff of the school and the health personnel.

In high school, a satisfactory relationship should be established between the school health service and the students, ideally between the school physician and each child. Present pre-occupation with finding defects must give way to securing a better understanding of each child's characteristics and needs, and in conveying this understanding to him and his family. Motivating both the child and his family to constructive action is an important objective. For this purpose, health interviews are of greater importance than routine screening examinations.

Summary

I have implied many challenges to our child health services with the intent of stimulating all workers to be alert to opportunities for improving them. Much progress has been made in recent years, but we are still a long way from meeting all the health needs of every child at all stages of his development.

Primarily, health services for children need to be more integrated, both in relation to the needs of the moment and from age period to age period. Also, health counsel should be based on an understanding of the growth progress and the individual attributes of each child. We cannot expect to attain these goals within the foreseeable future, but we must keep alert to improve those aspects which, admittedly, are unnecessarily weak.

Progress in Water Pollution Control

By CARL E. SCHWOB, M.S., and LEONARD B. DWORSKY, B.S.

"Water pollution has become a matter of grave concern in many areas, and its damaging effects on the public health and natural resources are a matter of definite Federal concern as a menace to national welfare. Abatement must be undertaken in order to control it." So stated the Senate Committee on Public Works in its report (S. Rept. 462, 80th Cong.) on the bill which was later enacted as the Water Pollution Control Act of 1948.

Recognizing this Federal concern, but also the primary responsibilities of the States in controlling water pollution, this act authorized the Public Health Service to take the initiative in developing or adopting comprehensive programs for the solution of water pollution problems in cooperation with the States, interstate agencies, municipalities, and industries. The act stated that comprehensive programs were to be developed for surface and underground waters, giving due consideration to all water uses—public water supply, propagation of fish and aquatic life, recreation, and agricultural, industrial, and other legitimate uses. It provided for Federal grants to the States and interstate agencies to help them carry out industrial waste studies, and for loans to municipalities to assist in the construction of needed abatement works. The latter provision was included with the intent that "The extension of Federal credit to local agencies for construction

of pollution abatement works will greatly stimulate the construction phase of the comprehensive program and thus encourage the early accomplishment of urgently needed abatement measures" (S. Rept. 462, 80th Cong.).

The act further provided for Federal research and technical and consultative assistance to State and interstate agencies, municipalities and industries, and for the encouragement of uniform State laws, interstate compacts, and cooperative State activities in the field of water pollution control. Initial responsibility for enforcement of pollution control measures was left with the States; Federal authority was to be exercised only on interstate waters, only after the efforts of the States had been exhausted, and only with the consent of the States.

To accomplish these tasks, a Division of Water Pollution Control was set up in the Bureau of State Services of the Public Health Service in Washington, and 10 field units were established, located according to drainage basin areas. Each of these field units is staffed with four to seven engineers and scientists who have had extensive experience in water pollution control work. The accompanying map shows the basin areas. The Environmental Health Center at Cincinnati serves as the research facility on water pollution problems.

Thus far \$5.38 million has been made available for Public Health Service activities under the act. An additional \$2.9 million has been provided for grants to State and interstate agencies for industrial waste research and investigations, and \$4 million, the full amount authorized, has been provided for the new Environmental Health Center research facility at Cincinnati, construction of which is about 65 percent completed. No funds have been

Mr. Schwob has been chief of the Division of Water Pollution Control, Bureau of State Services, Public Health Service, since its creation in 1948. Mr. Dworsky is chief of the reports and education branch of the division.

made available for the extension of Federal credit to assist local communities in the construction of treatment works.

In general, the multiple functions of the Division of Water Pollution Control fall into three broad categories: planning and development of comprehensive programs, execution of the programs, and technical services and research. Some of the activities, however, fall partly into one and partly into another of these groups.

Drainage Basin Reports

During 1949 and 1950, water pollution data available from State and Federal sources were assembled and analyzed. The information, covering 226 river basins in the United States, of which 146 are interstate, has been made available in 15 drainage basin reports, representing joint statements of the Public Health Service and the States involved. These reports provide, for the first time for most of the Nation, the names of the cities and industries that are creating pollution and are thus responsible for its abatement.

The data in these reports have been sum-

marized and published in a national inventory of the water pollution problem, "Water Pollution in the United States." This summary indicates that in July 1950 there were more than 22,000 sources of pollution in the United States—11,800 municipal sewer systems and 10,400 independent factory waste outlets. It reports further that despite the reduction of pollution by 9,300 treatment plants in operation, including 6,700 municipal and 2,600 industrial plants, wastes still discharged into rivers and lakes are equivalent to those from a population of over 150,000,000. To handle this volume of polluting wastes, 6,600 more municipal sewage treatment plants or additions to present plants and 3,500 more industrial waste treatment plants or additions will be required. An estimated \$9 billion to \$12 billion in public and private investments will be necessary over the next decade to meet these needs and to keep up with industrial expansion and population growth.

Reporting and Education Program

Often in the past it has not been possible, even after publication of reports and surveys, to

press forward on developing methods and procedures for making use of the facts. The reporting and education program developed under the provisions of the Water Pollution Control Act has made good progress toward getting the facts before the people who are in a position to use them.

Through the official State water pollution control agencies, the drainage basin reports are being made available to local community leaders and organizations, since the people in each community must take the steps necessary for the solution of their own problems. Many national organizations, such as the General Federation of Women's Clubs, the Rotary Clubs, the Kiwanis Clubs, and the Izaak Walton League of America, are also helping to get this information to the local communities.

In connection with the assembling of data, assistance has been given to State and interstate agencies in the conduct of studies, surveys, and investigations. Surveys of more than 88 streams and coastal water areas and investigations of almost 150 technical pollution problems have been made. By thus pooling State and Federal resources it has been possible to carry out many studies which, alone, neither the Public Health Service field staff, State nor interstate personnel would have been able to undertake.

Uniform State Policies

After analyzing existing State water pollution control laws and after consultation with State and municipal groups, conservationists, industrialists, and other individuals interested in water pollution control, the Public Health Service developed a Suggested State Water Pollution Control Act. The Council of State Governments endorsed and recommended it to the States for favorable consideration. Even before this model law was fully developed, the Service made its staff available to States requesting information on proposed legislation, and it is continuing this practice.

Although most State legislatures have met only once since the development of the suggested act, its principles have already been utilized in enacting new water pollution control legislation or major amendments to existing legislation by Arkansas, Illinois, Kentucky, North

Carolina, Ohio, South Carolina, and Vermont. Specific principles of the act have been reflected in legislation which strengthened the water pollution laws of Maine, Minnesota, New Hampshire, and Tennessee, and legislation based in large measure on the suggested act has been prepared for or introduced in the legislatures of many other States (Arizona, Colorado, Idaho, Missouri, Montana, Nevada, and Utah are examples). Thus progress toward achieving uniformity in the policies of the various States is being made.

The Public Health Service works closely with other Federal agencies on water resource problems by providing basic data on water quality, water use, and water pollution control measures, and by participating in the activities of the Federal Inter-Agency River Basin Committee and several similar field committees in various areas of the country.

Interstate Problems

During the first 3 years of operation, no formal enforcement action was attempted. Nevertheless, the Public Health Service has worked directly with a number of State agencies toward solution of interstate pollution problems. The Water Pollution Control Act has been important in making it possible for the Service, acting as a third party, to assist in solving interstate problems without resorting to the act's formal enforcement proceedings.

Assistance has been given in the formation of regional pollution control councils in areas not covered by formal interstate compact groups. Such councils now exist in six drainage basin areas. Acting in an advisory capacity, they provide a means for facilitating cooperative action by the States in a manner similar to that provided by the 10 interstate agencies which have formal compact arrangements. The Pacific Northwest Pollution Control Council, for example, has brought about the adoption in its area of uniform water quality objectives and treatment works design standards.

Grants to States

To help in the execution of the State water pollution control programs, the Congress made

available grants to the States for studies, surveys, and research on water pollution caused by industrial wastes. As a result State activities have been substantially increased in both dollars and manpower (see table). In 1950 the States spent slightly more than \$2 of their own funds for each dollar provided by Federal grants. By 1952 they were proposing to spend almost \$4.50 of their own funds for each dollar of the Federal grants. By 1952 the number of professional personnel employed by the States for water pollution control activities had increased 71 percent over the total for 1949.

State funds expended and personnel employed by State water pollution control agencies, 1949-52

Year	State expenditure (excluding Federal grants)	Total professional and scientific personnel	Professional and scientific personnel employed for industrial waste studies
Total	\$9, 243, 550	-----	-----
1949	(¹)	307	(¹)
1950	2, 242, 478	418	173
1951	2, 984, 492	440	234
1952 ²	4, 016, 580	525	285

¹ No data available.

² Estimated.

Approximately 70 percent of the grant funds have been expended in studies and investigations of existing industrial pollution problems. In the first 2 years of the grant program, more than 260 major stream surveys were made by the States. These involved comprehensive sampling, laboratory analyses, location of pollution sources, and determination of effects on the stream. In addition, well over 3,000 individual pollution problems caused by the wastes of specific industrial plants were investigated.

The basic facts obtained through these field investigations permitted many States to accelerate determinations of pollution control measures required for industrial waste pollution sources, and they will be useful in stimulating needed construction.

Expanding field activity made it necessary

for many States to enlarge laboratory facilities. Approximately 15 percent of the grant moneys were utilized for this purpose. Nineteen States have established new or expanded existing laboratory facilities, seven of them utilizing field laboratory trailers. Twenty-five other States have supplemented their laboratory equipment. The bacteriologists, chemists, and biologists added to staff the laboratories enabled some States for the first time to support adequately the activities of their sanitary engineering personnel.

Most of the State water pollution control agencies have felt that their greatest need was additional information in regard to the location and strength of industrial waste pollutants and the effects of these discharges in the receiving waters. Eighteen States have utilized grant funds for actual research on industrial wastes, and a considerable number of other States are supporting research programs with State appropriations. These studies include the phosphate mining and citrus wastes of Florida; the potato starch wastes of Idaho; the synthetic resin, paper de-inking, dye and textile wastes of Massachusetts; the vegetable and fish canneries wastes in Washington; and the metal-plating industry wastes in Ohio. Approximately 15 percent of the total grant funds have been utilized for research purposes.

Technical Services

The phrase "provide technical service" no longer means, as it once did, the assignment of a single, well-qualified individual to study a problem and produce an answer. In water pollution, as in so many of the problems in the world today, one science merges with another—chemistry with biology, biology with physics, and so on. In searching for ways to overcome pollution, there is need for a coordinated approach. The assistance which the Federal Government today extends to States, industries, and others under the heading "technical service," is really the combined services of sanitary and chemical engineers, biologists, and bacteriologists—men representing many branches of scientific knowledge.

For example, assistance has been requested in reviewing proposed programs and activities of

the States, in guiding the development of uniform water quality standards, and in determining beneficial water uses for subbasin areas.

Requests are continually received for field technical people to participate in conferences, technical meetings, and similar discussions on a wide variety of pollution problems: (a) methods of controlling nuisance growths of algae and other aquatic vegetation which interfere with recreational uses of water; (b) effects of sewage-polluted irrigation water on public health; (c) causes of fish mortality; (d) toxicity of insecticides on aquatic life; (e) effects of industrial wastes on public water supply and on fish life; and (f) possible utilization of certain industrial wastes.

An illustration of the kind of technical service provided relates to the pulp and paper industry. The Public Health Service has worked with industry officials and with the States in determining sites for new pulp mills in the Pacific Northwest and in Alaska in order to safeguard the valuable salmon and other migratory fish which are found in these areas.

National Technical Task Committee

In keeping with the stress placed by the Congress on helping solve industrial waste problems, particularly those concerning industrial wastes for which there are now no known effective treatments, the National Technical Task

(Continued on page 1086)

CASE STUDY OF A COMPREHENSIVE PROGRAM

Pollution Control in the Upper Snake River Basin

AN AUTHENTIC ILLUSTRATION

The following illustrations describe the steps in the development of a comprehensive program of water pollution control. The Upper Snake River Basin, which crosses four State lines, is used as an example. (Illustrations reproduced from "Environment and Health," Public Health Service Publication No. 84, 1951.)

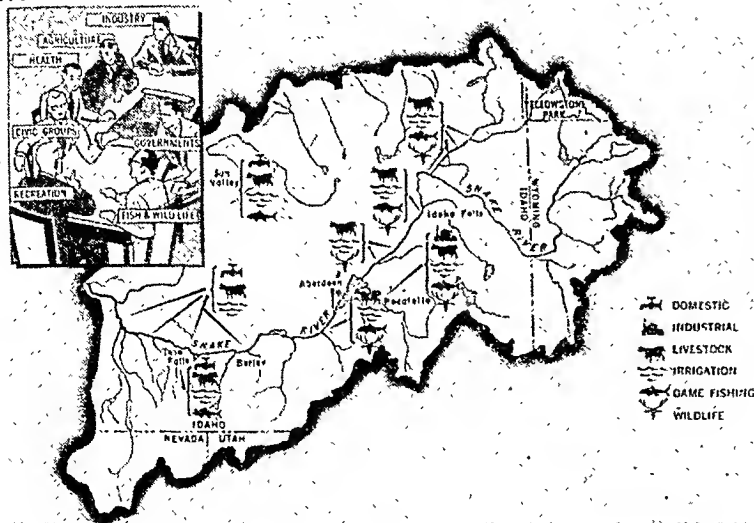

Technicians must seek out sources of pollution and determine the amount and kind of pollution in each case. If necessary, laboratory data are developed to clarify understanding of the sources, character, and effect of pollution.

1....DETERMINE EXISTING STREAM POLLUTION CONDITIONS

THE AREA OF EACH CIRCLE IS PROPORTIONATE TO QUANTITY OF WASTES DISCHARGED.

2...DETERMINE MOST SUITABLE STREAM USES

The best use of the waters of streams must be determined before waste treatment plants are built because treatment of wastes will vary according to the quality of the water desired. Water pollution control authorities help by gathering, reviewing, revising, and interpreting data.

3...DETERMINE STANDARDS OF WATER QUALITY

If we want to use water for the purposes indicated in the first column below... we must do:	terme the quality for each use according to the amount and intensity of the following elements:
DOMESTIC WATER SUPPLY	Oxygen, bacteria, waste solids, acidity, alkalinity, color, clarity, odor, taste, oil sludge, plant life, chemistry
INDUSTRIAL WATER SUPPLY	Waste solids, acidity, alkalinity, temperature, color, oil sludge, clarity

BATHING AND RECREATION	Bacteria, waste solids, oil sludge
IRRIGATION AND AGRICULTURE	Waste solids, bacteria, oil sludge

4...PLAN AND CONSTRUCT TREATMENT PLANTS

Once the sources and amount of pollution are determined and decisions made as to the most suitable water uses, steps are taken to determine the degree of treatment required at each source of pollution. The construction of treatment plants can be expedited by industry, municipalities, and State, interstate, or Federal authority.

Committee on Industrial Wastes was formed on invitation of the Surgeon General of the Public Health Service in May 1950. To meet its broad objective of "effecting an improvement in the quality of water resources in the Nation," the Committee undertook "to perform technical tasks pertaining to industrial wastes in co-operation with the Public Health Service and all others concerned with improving the quality of our water resources."

The functions of the committee are, briefly, to inventory, appraise, coordinate, and promote research and development work, and to stimulate further adoption of known practical methods of pollution control and treatment. The committee also seeks to bring about more effective working relationships between industry and the various levels of government.

The group has 57 members, designated by their respective industries. They represent 36 major industrial categories, covering 10,000 individual plants. The categories include: automotive, beet sugar, canning, chemical manufacturing, mining, meat and poultry packing, dairy products, distilling, electric, electroplating, fermentation, iron and steel, nonferrous metals, petroleum, pulp, paper and paperboard, rubber, tanning, and textile industries.

Tremendous value can be derived from the coordinated research and pooling of information which is available from a group having this wide representation. Further, the committee has been of great value in directing efforts of the Public Health Service to most needed areas.

Environmental Health Center Research

The research activities of the Environmental Health Center are complex and scientific. They extend over a wide range of investigations in the fields of chemistry, physics, engineering, and biology.

Some of the areas in which work is currently in progress include the development and evaluation of analytical techniques for both organic and inorganic materials; studies of persistence of particular organic compounds in water; application of biological oxidation processes to waste purification; studies of industrial waste sources, characteristics, and corrective meas-

ures; inventory surveys on pollution of water resources; development of biological methods for determining the severity and extent of pollution; studies of toxicity of water pollutants to aquatic life; development of bio-assay methods and their application to pollution control; development of methods for control of organisms responsible for tastes and odors in water supplies; studies of the pollution and purification of shellfish in aquatic environments.

Recent field investigations of synthetic rubber, steel, and kraft paper mill wastes are cited as examples of specific studies made in the industrial wastes field. Another current study involves the determination of radioactivity in surface and ground water and in fresh water life. Still another relates to the determination of cyanide in water and wastes.

A recent product of Environmental Health Center research is a greatly simplified technique for measuring chemicals in water. This new procedure is a significant contribution to the fields of public health and water supply operation. The rapid expansion of this country's chemical industry during the past 10 years has brought increasing burdens of chemical wastes to our streams. Frequently, these wastes cause serious taste and odor problems in the public water supplies drawn from the streams. Possible hazards to public health because of these foreign chemicals are yet unknown. The advantages of the new technique over the old test-tube processes of chemical analysis, with respect to both cost and speed, will permit more rapid progress in determining the extent of the problem and the earlier development of means for handling it.

Future Outlook

The progress hoped for at the time the water pollution control program was developed has not been completely achieved. During World War II, construction of sewage treatment plants declined rapidly. After the war, construction resumed and the rate advanced fairly rapidly until by 1950 a rate well above the average for the previous 35 years had been attained. In 1950 the dollar volume of municipal treatment plant construction was about \$200 million. Then, shortages due to the defense build-up

Now available on loan is this three-panel exhibit recently developed by the Division of Water Pollution Control. It highlights the importance of pollution abatement in conserving our water resources and stresses the responsibility of communities and industries for cleaning up the pollution they create. Featured on the center panel is the five-color poster, "Help Fight Pollution Now!" The exhibit has been shown at several national conventions. Each drainage basin

office has a similar exhibit for use within its area.

The exhibit is designed for ease in handling. With the two end wings folded across the center panel (6' x 3') and the legs and lights (not shown) detached, the complete exhibit can be packed in one case weighing approximately 225 pounds. For information concerning availability and conditions under which this exhibit may be borrowed, write to: Division of Water Pollution Control, Public Health Service, Washington 25, D. C.

placed obstacles in the way of sewage works construction, and in 1951 the volume dropped to about \$175 million. Tentative figures covering the first two quarters of 1952 indicate that this year's rate may be slightly lower than that for 1951. An annual rate of construction almost three times that attained in 1951 will be required over the next decade in order to eliminate the backlog of municipal treatment plant needs and meet current needs as they arise.

Although data are not now available on progress in the abatement of industrial pollution, general indications point to the necessity of substantial acceleration.

Adding urgency to the need for elimination of industrial wastes from the streams, particularly those new types resulting from relatively recent developments in chemical and allied industries, is the realization that not only do those wastes destroy or reduce the usefulness of the streams they enter, they also pose problems in the treatment of public water supplies. Existing water purification methods have been notably successful in removing from drinking

water supplies the contamination caused by organic wastes. However, knowledge is limited as to the effectiveness of known methods of treatment for the many new types of pollutants—chemicals, phenols, synthetics, pharmaceuticals, and radioactive materials. There have already been numerous instances of taste and odor problems arising in public water supplies exposed to even minute quantities of such wastes. Basic information as to the physiological effects of such contamination is also lacking. Treatment of those wastes at the source, before they enter the streams, would remove this hazard to health and a complex water treatment problem.

If this country is to maintain its existence as a highly industrialized and urbanized nation, waste treatment works must be considered not as single-shot operations but as permanent facilities which must be maintained and preserved. Otherwise, water, the lifeblood of the Nation, will suffer, and all the difficulties that face a nation that has destroyed its water resources will follow.

The National Association of Manufacturers' report, "Water in Industry," has clearly stated the viewpoint of industry: "A shortage of water for industrial purposes—just as surely as a shortage of manpower, of materials, or of capital—could defeat our hopes for future growth and prosperity and even imperil our national safety. No industry or business can long survive where water is unavailable or inadequate as to quantity and quality."

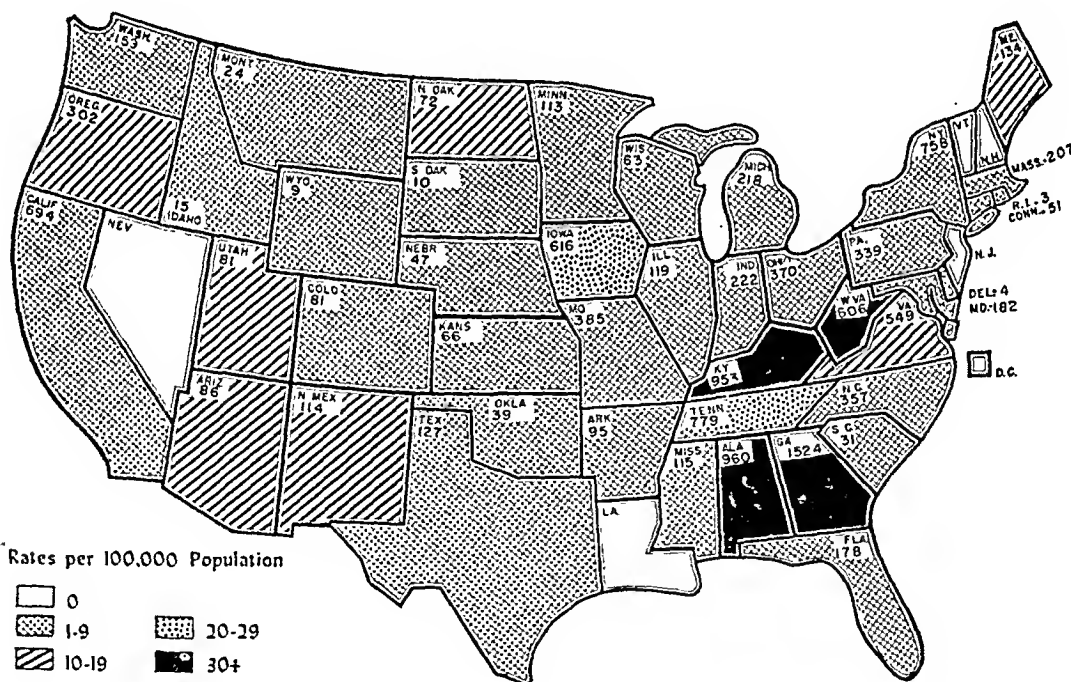

The report of the President's Water Resources Policy Commission, referring to the importance of pollution control to recreational uses of water, said: "No other phase of a water resources program promises so much toward expanding outdoor recreation opportunities as the cleaning up of our rivers."

On the need for pollution abatement to protect our fish and wildlife resources, the com-

mission commented: "Plainly, a pollution abatement program is essential to the future of our wildlife resources. The abundance of wild animals and fish that might result from such a program stirs the imagination."

It is evident that much remains to be done before the problem of water pollution can be considered reasonably under control. The Public Health Service feels that with the co-operative efforts of the States, the interstate agencies, municipalities, industries, and the Federal Government success must and will be achieved, and that with respect to water resources, at least, this generation will be able to meet the requirements set up by Theodore Roosevelt, when he said: "The Nation behaves well if it treats the natural resources as assets which it must turn over to the next generation increased and not impaired in value."

Incidence of Infectious Hepatitis by State

Regular weekly reporting by States of the number of cases of infectious hepatitis began in 1952.

The provisional total for the first 39 weeks of 1952 is 11,868 cases. All States reported except New Hampshire, New Jersey, Nevada, Vermont, and the District of Columbia. Georgia reported the largest number—1,524 cases. See map for

distribution of cases and rates (per 100,000 population) by State for the first 39 weeks of 1952.

Although comparable statistical data are not available for previous years, the distribution of the disease has not been different from that described in textbooks.

The incidence of the disease in 1952 was highest in the winter and

spring months. Epidemics have been reported most frequently from States with large rural populations. Many cases were found in school populations. In most instances, epidemiological evidence has pointed to a person-to-person spread of infection, although two outbreaks were reported where water was regarded as the vehicle of infection.

Food and Water Borne Disease Outbreaks

Incidence of Infectious Hepatitis by State

The importance of reporting outbreaks of food- and water-borne disease has been recognized for many years. As long ago as 1912, the State and Territorial health officers recommended that the occurrence of outbreaks of certain diseases, including dysentery and typhoid fever, be reported to the Public Health Service. By 1923, the systematic collection and publication of reports of outbreaks of milk-borne disease was under way. In 1938, reports became more comprehensive and included outbreaks of illness in which water and foods as well as milk were vehicles of infection.

Prior to 1951, reports of outbreaks were collected at the end of the year, and a report was issued in annual summary form. Beginning in 1951, reports were sought on a current basis—as soon as possible after an investigation of an outbreak was completed. Since summaries of individual outbreaks have been included in weekly reports issued by the National Office of Vital Statistics, this material need not be repeated. Instead, it is summarized here in a narrative review, with three summary tables.

Reduction in Outbreaks

Fewer disease outbreaks in which food or water was the transmitting agent were reported in 1951 than in 1950, but the number of persons affected was approximately the same. The reduction (table 1) was due almost entirely to a decrease in the number of outbreaks in which foods other than milk and milk products were the vehicles of infection.

Dr. Dauer is medical adviser to the chief of the National Office of Vital Statistics, Public Health Service.

The number of outbreaks of water- and milk-borne disease was reduced markedly—approximately one-half and two-thirds, respectively—between 1939–41 and 1949–51, the most recent 3-year period for which figures are available. Epidemics of milk-borne typhoid fever have declined (table 2) from an average of 12 per year in 1938–40 to about one epidemic annually in the period 1949–51; outbreaks of milk-borne streptococcal infection decreased similarly. The increase in the number of local areas that require pasteurization of milk and milk products and treatment and safeguarding of water supplies undoubtedly has been instrumental in reducing disease transmission by these vehicles. On the other hand, the actual number of reported epidemics in which foods other than milk or milk products were the vehicles of infection has increased in the last decade. This probably reflects more complete reporting rather than any real increase in frequency of such outbreaks.

Faulty methods of handling food and poor hygiene on the part of food handlers were frequent findings in investigations of outbreaks of food-borne disease in which foods other than milk were the vehicles of infection, according to 1951 reports of such outbreaks. In one-third of these epidemics refrigeration was found to be either inadequate or absent, especially in outbreaks in which cream-filled pastries, meats, and salads were the vehicles of infection. Storing meats in a warming oven or steam table for several hours before serving was another practice conducive to bacterial growth. Food handlers with “sores” or dermatitis on their hands, and others having sore throat, colds, or even diarrhea, were sometimes permitted to prepare or handle easily contaminated foods.

These findings indicate very clearly that many persons operating or employed in food establishments do not appreciate the importance of proper handling of foods and of good personal hygiene in preventing food-poison and food-infection outbreaks.

Data Analysis Difficult

Satisfactory statistical treatment or analysis of the data from reports of outbreaks of food poisoning or food infection is usually not possible. The very nature of the outbreak sometimes precludes an actual count of the persons affected, and only an estimate of their number can be reported. The interval between onset of illness and reporting of cases, as well as variation in types of investigation, is sometimes responsible for differences in completeness of reports. Samples of food served to persons ill in an outbreak of food poisoning may not have been available for laboratory testing; therefore, it would be "postulated" that the vehicle of infection was a given food which had been eaten by all, or nearly all, persons made ill and not eaten by those not ill.

Data obtained from reports of outbreaks of certain diseases represent only a fraction of the total cases of those diseases noted in routine weekly reports from the various States, while

nearly equal numbers of other diseases are reported in both weekly and outbreak reports. Apparently, efficiency of reporting mechanisms rather than an actually greater occurrence of epidemics is reflected by the larger number of outbreaks of food- and water-borne diseases reported by some States. Perhaps the medical profession in these States is more conscious of its responsibility for prompt reporting of these diseases, personnel are available for investigations, and local or city health officers work in unison with the State health officer.

Lack of appreciation of the importance of prompt reporting and investigation of all food-poison and food-infection and other common-source outbreaks, or lack of personnel and facilities for investigation would seem to be indicated by the fact that 18 States made no reports of such outbreaks in 1951. In States with small populations, perhaps no outbreaks were brought to the attention of the State health officer, but this is not a reasonable assumption for States with large populations.

Vehicle of Infection

Milk and Milk Products

In four reported outbreaks of disease, milk apparently was the vehicle of infection. Only

36 persons were affected in these outbreaks, each caused by a different organism, *Salmonella typhosa*, *Salmonella paratyphi B*, *Streptococcus viridans*, and a staphylococcus. Raw milk was involved in three of the four outbreaks; in the fourth, pasteurized milk was used, but it was found that there had been opportunity for contamination after pasteurization. One outbreak involved 10 families, totaling 40 individuals, who were supplied from a herd of cows in which one animal was found to have an "infection" of the udder. Both hemolytic staphylococci and hemolytic streptococci were found in samples of milk from this herd. The other outbreaks are described below.

An ill-defined group of illnesses was observed in 10 children who had been drinking canned milk. The illnesses ceased when another milk product was substituted.

Ice cream was the vehicle of infection in 3 outbreaks of food poisoning in which 42 persons became ill. The infective agents in these outbreaks were, respectively, *Salmonella oranienburg*, *Salmonella typhimurium*, presumably from duck eggs, and a staphylococcus.

Raw buttermilk, from which a staphylococcus was isolated, was believed to be the source of infection in a small outbreak of illness in one family. Fruit cottage cheese, from which *Es-*

cherichia coli was isolated, was regarded as the vehicle of infection in another small outbreak, and in two others processed cheese caused symptoms of food poisoning.

Other Foods

Contaminated foods other than milk, milk products, and shellfish were the cause of nine-tenths of the common-source outbreaks of food poisoning reported in 1951 (table 3). In 53 outbreaks poultry meat and eggs were found or suspected to be the vehicle of infection. Of these, 8 proved to be caused by *Salmonella*, which suggests that the fowl or eggs were naturally infected. Processed hams, frequently precooked, were the source of infection in 38 outbreaks, nearly all of them due to a staphylococcus. Beef, usually roasted, was found to be the probable source of infection in 32 outbreaks, and miscellaneous meats in 25. Custard-filled pastries were another common vehicle of infection. There was bacteriological or epidemiological evidence that eclairs, cream puffs, cream pies, and similar types of pastry were the vehicles of infection in 34 outbreaks. Salads, fish, sandwich fillings or spreads, and creamed vegetables were suspected of being the source of infection in 34 outbreaks. In some outbreaks the exact vehicle of infection could not be de-

terminated because the outbreaks were reported too late to be investigated, because samples of food could not be obtained, or because the investigation was not completed.

Shellfish

Shellfish were regarded as the source of infection in only one outbreak. Twelve cases of an unidentified type of infection followed the eating of hard-shelled clams. Improper and unsanitary handling of the clams in a restaurant was believed to be responsible for the outbreak rather than contamination at the source of supply.

Water

Bacteriological evidence of contamination or epidemiological evidence suggesting that water was the vehicle of infection was present in seven reported outbreaks of water-borne disease. In one instance, an estimated 3,500 persons in a Michigan town of 7,600 population became ill with diarrhea following a heavy rainstorm. Surface water had flooded the wells used as the public water supply. Samples of water taken 4 days after the storm showed no pathogenic organisms on bacteriological examination. Another outbreak of diarrhea followed the breakdown of chlorinating

equipment of a well-water supply used by a summer hotel. During the breakdown, water was obtained from a spring known to be an unsatisfactory source of drinking water. A third outbreak occurred in a summer camp for children, where the piping system allowed inadequate contact of lake water with chlorine, and 60 to 80 persons became ill on two different occasions. No more cases occurred after the defect was corrected. Other outbreaks included a group of 300 cases of infection among persons who had used unchlorinated water from a spring reservoir known to be unsatisfactory, and a small group of cases among persons using water from a well having a high "coliform count." There was one outbreak of 18 cases of bacillary dysentery in which the infection was traced to a well in close proximity to a pit privy.

In none of the above outbreaks was an organism of the typhoid or *Salmonella* groups found or reported.

An unusual type of water-borne disease was reported in Oregon, where 22 persons using a swimming pool developed keratoconjunctivitis. Treated river water that conformed to accepted standards of purity for drinking water and amounts of residual chlorine was used in the pool.

Two outbreaks of infectious hepatitis were reported in which water was considered to be a possible mode of transmission, but proof was lacking.

Type of Agent

Staphylococcal Food Poisoning

In 63 outbreaks of food poisoning reported in 1951 the presence of a staphylococcus in the food was demonstrated by laboratory tests. Cream-filled pastries, mostly cream pies, cream puffs and eclairs, were the vehicles of infection in 18, or nearly one-third, of all staphylococcal food-poison outbreaks. Lack of or inadequate refrigeration was noted in 20 of the outbreaks, and in 3, the persons who prepared the food were reported to have "sores" on their hands.

Ham, usually baked, was also found to be the vehicle of infection in 27 outbreaks. In nine of these, inadequate refrigeration of the meat was noted.

In three outbreaks, milk or milk products were found to be contaminated with staphylococci. Four outbreaks were reported in which a salad was the vehicle of infection; in three of these, inadequate refrigeration was observed. Poultry meat (commonly turkey), salads containing such meat, and dressing used to stuff poultry, were reported in five staphylococcal food-poison outbreaks. A typical outbreak of this kind occurred in Wyoming. An auction sale of livestock was attended by 500 to 600 persons from three different States. Chicken salad sandwiches, prepared the day before the sale and left unrefrigerated, were served. Seventy-five persons became ill 2 to 8 hours after eating the sandwiches. On laboratory examination, *Staphylococcus aureus* was recovered from samples of this food.

A variety of meats, including roast beef, lunch meat, bologna, and pastrami, were also proved or suspected to have been the vehicles of infection in 38 outbreaks of food poisoning. Such an outbreak occurred in Connecticut following a banquet at which roast beef was served after being allowed to stand on top of a cooking range for 12 hours after roasting. An estimated 120 persons became ill, all of whom had eaten the roast beef. *Staphylococcus aureus* was found on culture of samples of the meat

and in nose cultures of 10 food handlers who had had a part in cooking and serving it.

Peas and kippered herring, respectively, appeared to be the vehicles of infection in two outbreaks of staphylococcus food poisoning, according to reports of epidemiological investigations.

Typhoid Fever

Only three outbreaks of typhoid fever were reported in 1951. In one outbreak, 30 cases and 1 death occurred in an institution in New York State with a population of 375 inmates. Onsets of illness occurred over a period of 10 weeks, January 17 to March 28. While a common source of infection was suspected—food or milk contaminated during serving—this could not be proved, nor was the source of infection traced.

In Texas, an outbreak of 12 cases followed a banquet attended by 175 persons. Neither the vehicle nor the source of infection was identified.

In Oregon, raw milk supplied by a neighborhood dairy was the source of infection in two members of one family. The operators of the dairy, a man and his wife, were found to be carriers of the same phage type of organism, namely (F-1), as that isolated from these two patients.

In addition to the 44 cases cited above, there were slightly more than 2,100 cases of typhoid fever reported in the country as a whole in 1951. Many of these may have been infected by water, milk, or other foods, the real source of infection probably being a carrier having direct or indirect contact with these vehicles of infection. However, proof that a particular food or water supply is involved is difficult to establish when only one or two cases are associated with the presence of a carrier.

Salmonellosis

Fifteen outbreaks of *Salmonella* infections, with 850 clinical cases, were reported in 1951. Eight different types of the organism were found. *S. typhimurium* was isolated in six outbreaks, *S. oranienburg* and *S. montevideo* in two each, and *S. newport*, *S. dublin*, *S. give*, *S. morgani*, and *S. paratyphi B.*, in one each.

Poultry meat or eggs were found to be the vehicle of infection in 8 of the 15 outbreaks of

Salmonella infection. *S. typhimurium* was found in four outbreaks. Home-made ice cream in which duck eggs were used caused illness in 30 persons; turkey eggs were an ingredient of eggnog which was found to be the vehicle of infection in another epidemic due to *S. typhimurium*.

Ten cases of milk-borne *S. paratyphi B* infection were traced to the nephew of a dairyman. For about a week just prior to the epidemic the boy had visited the dairy farm and had helped in handling the milk, which was not subject to pasteurization. In 1948 this boy had been found to be a carrier of *S. paratyphi B*, and in 1950 there was evidence that he had been the source of infection of a case of salmonellosis in his home town.

Salmonella infection associated with poultry meat occurred in California. Forty-one of forty-six persons became ill from 3 hours to 3 days after a pre-Christmas buffet luncheon. *S. newport* was recovered from eight of the ill persons and from portions of cold sliced turkey, sliced tongue, and potato salad. The turkeys, the tongue, and the salad ingredients had been prepared by one person and had been sliced on the same board.

Spaghetti, chopped liver, baked ham, cream filling in chocolate eclairs, and baked Alaska also appear to have been the vehicles of infection in outbreaks of salmonellosis. In some instances the type of infection was established by isolation of the organism from stools of those who were ill.

Streptococcal Disease

Milk was incriminated in only one of the eight outbreaks of illness reported due to a streptococcus. One case of mastitis was found on a farm where milk supplied to a hospital was produced and pasteurized. Infection by a food handler in the hospital was also possible.

Many varieties of food were reported to be the vehicle of infection in outbreaks of streptococcal disease, but in several instances bacteriological tests were not conclusive. Although the vehicle of infection was not identified in an explosive outbreak of 150 cases in a hospital, a dietitian had a throat culture showing streptococci and a food handler had a sore throat just before the outbreak began.

Miscellaneous

Seven outbreaks of trichinosis were reported during the year, involving 32 cases with no deaths. Poorly cooked "local" pork, home-made sausage, and ham were reported as the types of pork eaten.

A chemical was considered to be the cause of illness in six reported outbreaks of food poisoning. In five instances, exposure of soft or fruit drinks to copper vessels or utensils was regarded as the probable means of contamination.

There were two reports of mushroom poisoning in which nine persons became ill and two died. Six children mistook the roots of water hemlock for an edible plant; three of the six died.

During the year nine reports of botulism outbreaks were received. Twenty cases and 12 deaths were reported. Type A and type B botulinus toxin were identified in two instances each. Home-canned vegetables were involved in seven instances, a commercially processed cheese in one, and an undetermined vehicle in one.

Six outbreaks of gastroenteritis, involving 398 persons, were reported. In four, an organism of the paracolon group was recovered from food samples; in two, *E. coli* was isolated in large numbers. In one outbreak, 93 of 155 persons attending a meeting on milk and food sanitation became ill after eating creamed turkey. Large numbers of aerogenes-like paracolon organisms were recovered. Of the other five outbreaks, turkey meat was involved in three, roast beef in one, and fruit cottage cheese in one.

Undetermined Vehicles of Infection

Ninety-two outbreaks of illness were reported in which no determination of type of infection could be made from the details recorded. When the 92 outbreaks were grouped according to incubation period, 44 fell into the group of "suspect" staphylococcal food poisoning; 36 had incubation periods of 8 to 24 hours or longer, suggesting food infection; and in 12, the incubation period was not reported.

In many instances, no laboratory examination was possible, because all suspected foods had been eaten or left-over portions had been

disposed of before the outbreak was reported. A typical report of this kind was sent from Maine. A family of 11 persons had eaten roast capon and a salad for Christmas dinner. Twenty-one to 24 hours later 8 persons were ill, but by the time the cases were reported for investigation none of the food remained. Stools of the patients showed no pathogenic organisms.

Other Types of Disease Outbreaks

Shigellosis

There was only one report of an outbreak of *Shigella* infection with definite evidence of transmission by food or water, and seven outbreaks were considered to be person-to-person types of infection. *Shigella sonnei* was isolated in six instances, and a flexneri type of organism in one. Four outbreaks occurred in institutions, one each in a summer camp and a school, and two were family outbreaks. In the eight out-

breaks, 381 persons were reported to have been ill, the cause of 43 of the illnesses was confirmed by a laboratory examination of stools. In one epidemic of 153 clinical cases, the exact number confirmed by a laboratory test was not given.

Diarrhea of the Newborn

Five outbreaks of diarrhea of the newborn were reported, four in New York State, and one in Illinois. Fifty-four cases with two deaths were reported. The means by which the infection was introduced were not determined in any of the five outbreaks, although in two instances contact with an infected person was considered to be the most likely mode of spread. In one small outbreak of three cases, an organism of the *Salmonella* group was isolated from the stools of one infant, and a sample of the food formula yielded an aerobic spore-bearing organism. The outbreak in Illinois was explosive in character, and occurred simultaneously with reports of transient diarrhea in the general population served by a hospital.

Public Health Service Appointments

Three appointments in the Public Health Service have recently been announced.

Dr. Joseph F. van Ackeren was named chief medical officer of the Coast Guard, effective October 1, 1952, to succeed Dr. Paul M. Stewart, who has retired after 37 years with the Public Health Service. Dr. van Ackeren has served as medical officer in charge of the Public Health Service Hospital, Seattle, Wash., since 1944. His previous assignments include similar positions in the Public Health Service, Out-Patient Clinic, Washington, D. C., and in the Public Health Service Hospital, Baltimore, Md.

Dr. James Payson Dixon has been appointed acting assistant director of the Public Health Service's new 500-bed Clinical Center for research at the National Institutes of Health in Bethesda, Md. He has been health commissioner for Philadelphia since January 1952, as well as serving as professor of public health and preventive medicine at the University of Pennsylvania School of Medicine.

The new chief of the bacteriology laboratory of the Communicable Disease Center, Public Health Service, is Dr. Donald S. Martin, formerly dean of the University of Puerto School of Medicine. From 1932-50, Dr. Martin was on the faculty of the University of Rochester School of Medicine intermittently and on the faculty and staff of the Duke University School of Medicine and Duke Hospital. He succeeds Dr. Martin Frobisher, Jr., who has become chairman of the new department of bacteriology, University of Georgia, Athens.

The Local Public Health Officer in Great Britain Today

By SIR ALLEN DALEY, M.D., D.P.H.

The British public health service comprises about 2,000 full-time medically qualified health officers, the vast majority of the officers in local posts that between them cover the health needs of all parts of the country.

In addition, large numbers of medical officers have part-time work as specialists, clinic workers, and chest physicians in health departments and as officers in children's homes and welfare institutions.

Of the full-time officers, about 60 are in the Ministry of Health of England and Wales. The local health government in England and Wales has 145 major units—83 county boroughs and 62 counties—called the "local health authorities." Each has a medical officer of health—a term corresponding to health commissioner or health officer in the United States.

The 83 county boroughs, corresponding to cities, are "all purpose" authorities. Their health officers have responsibility for all the public health work of their cities, which range in population from just under 100,000 to more than 1,000,000.

Sir Allen Daley, a medical officer of health in England for more than 40 years and with the London County Council from 1929 until his retirement in February 1952, served as associate health officer of the Baltimore City Health Department from March to July 1952. He presented this paper before the health officers section of the Southern Branch of the American Public Health Association at the annual meeting in Baltimore, Md., April 17, 1952.

The 62 counties, responsible mainly for the personal health services such as maternity and child welfare and school health, have a complex system of health administration. Many are predominantly rural, cover wide areas, and contain a number of small towns. Others, like the London County Council, and the Middlesex County Council, which is on the fringe of Central London, are predominantly urban and have large populations.

Each county is subdivided into sanitary districts. Larger counties are also divided into divisions for health administration purposes.

In all of England and Wales there are 1,400 sanitary districts. The average number per county is about 17. But some of the small counties with populations of less than 100,000 have only two or three, and some of the larger ones with populations of more than a million have 40 or 50. Each of these sanitary districts must appoint, by law, its own health officer. He has responsibility, independent of the county health officer, for general sanitation, purity of food, and the control of infectious diseases.

To administer the divisions, the county appoints a divisional health officer who is on the staff of the county health officer and is subordinate to him. In counties with large populations or covering wide areas, such as London with its large population or Lancashire, which is more than 100 miles long, the counties have decentralized their functions, and it is now common for a district health officer to be also an assistant county health officer. This assignment gives him a full range of duties. He acts

independently as a district health officer for environmental hygiene, but as the agent of the county health officer for the personal health services in his area. The theoretical objection to his serving two or more masters is not serious in practice. This complication does not occur in the county boroughs (the large cities), where the health officer is assigned the whole field.

The London County Council

The health administration of the County of London is rather complex. This area of Central London, with its population of 3.5 million people is known as the London County Council, or the L. C. C. It has nine divisions for the purpose of county health administration, each with its divisional health officer responsible to the county health officer.

Within the same London County Council area there are 28 sanitary districts, or metropolitan boroughs as they are officially called, each with its own medical officer of health. Thus, a division includes from two to five sanitary districts. The districts (or boroughs) range in population from 30,000 to over 300,000. As so often happens, this disparity depends on history, the original boundaries dating back for centuries. In addition to the 28 sanitary districts, or metropolitan boroughs, there is, within the County of London, the ancient City of London with an area of 1 square mile, compared with 117 square miles in the County of London. It is, technically, a sanitary authority, though with wider functions than the 28 metropolitan boroughs, and its medical officer of health is always a senior and distinguished member of the public health service.

Outside the County of London there is the "overspill" population which, particularly during the past 50 years, has overflowed the boundaries of the London County Council. This overspill population is now about 6,000,000 and together with the County of London forms an urban aggregate of nearly 10,000,000 people, colloquially known as "Greater London." It is administered as one unit for police and traffic purposes, but no political party has had the courage to try to get sense into its problems of health administration, and the "outer fringe,"

as the area outside the County of London is called, contains three county boroughs, the county of Middlesex, portions of five other counties, and a host of sanitary districts.

Transfer of Functions

The trend is to transfer functions from the smaller district units to the larger county authorities, and from the large units—counties and cities—to the central government. For example, the maternity and child welfare work formerly done by the districts has been transferred to the counties, and all hospitals and the clinical part of tuberculosis and venereal disease work has been transferred from the counties to the central government.

The only functions now remaining with the districts are environmental hygiene in its broadest sense, and also the purity of water, milk, and food, the receipt of notifications of infectious diseases, and prevention of the spread of those diseases. There are encroachments even in this limited field. Generally, engineers are put in charge of water and sewage disposal undertakings and of the collection and disposal of garbage and trash for which many health officers were at one time responsible. Further, some counties, such as London, are given responsibility for major rehousing. In epidemiology, the district health officer must send to the county health officer copies of the notifications of infectious diseases within 36 hours of their receipt. In London, the County Council has power to step in and take over the work if the district defaults in its duty.

The counties have many important duties in the field of personal health. Maternity and child welfare includes receipt of notifications of birth, public health nursing, a midwifery service and antenatal clinics, infant welfare clinics, day nurseries, and recuperative holidays. Counties also provide school health service which, on the whole, is more highly developed than in the United States; vaccination, and immunization; a dental service for mothers and children; a home nursing and domestic help service; a general program of prevention and after-care of all types of disease; an ambulance service not only for accidents but also for transport to and from hospitals; ascertainment and non-

institutional care of the mentally defective; a 24-hour service for taking into custody persons of disordered mind, and a host of other functions.

Impact of Nationalized Hospitals

In Britain, it is common form to administer by the horizontal, as opposed to the vertical system—that is, the lawyer, the doctor, the engineer, and the architect do the legal, medical and nursing, the engineering and the building work for the entire local government unit. By contrast, in the vertical system, the education department, for example, would have its own doctor and architect on the staff of the education officer or superintendent of schools. Under the horizontal system, the functions of health officers, who had responsibility for the municipal hospital service, were expanding somewhat rapidly until the hospitals were nationalized in 1948.

Some health officers transferred to administrative positions in the hospital service. Most, however, remained in the health service, and many regarded the nationalized hospital service as a major inroad on local health administration. Although the advantages to the local health officer of direct control of communicable disease hospitals and sanatoriums, and of all the work of tuberculosis dispensaries and venereal disease clinics are obvious, it is not so clear that he need concern himself with the details of the administration of general or mental hospitals. There is, however, still much important work for the health officer to do. He must study morbidity in his area and see what can be done to reduce it, particularly that due to psychoses and psychoneuroses. The cost of the curative services is heavy and it is obvious that preventive measures must be supported to an increasing extent.

The importance of "social medicine" is being recognized. Problems of the care of the aged now face the health officer. In some areas, the health officer has been appointed welfare officer as well because the care of the aged and infirm interlocks with medical and nursing problems.

The recent changes, however, have had an unsettling effect on the public health service, and a couple of years ago only a handful of

students in the schools of public health expressed a desire to become health officers in Britain. Most of the public health students were destined for the colonial services or the medical departments of the armed forces.

Until World War II, there was no shortage of good recruits for the health departments. Apart from those attracted to this work for its own sake, some entered it because it gave a salaried post on a full-time basis to a man without the capital then necessary to buy a general practice or on which to keep himself while preparing for a specialist career. With the advent of the National Health Service Act, all this has changed. The sale and purchase of general practices has been prohibited by law, and, except for the purchase of a house, capital is not now needed to set up in practice. Interns and residents are paid a living wage; specialists are paid for their hospital work and at a level substantially above that of the average full-time health officer.

Salaries Fixed

Before the war, health officers were reasonably content with their salaries. Although a minimum salary for each type of post had been settled on a national basis in 1929, there was local option, and in many areas much more was paid than the minimum. The National Health Service Act provided that the Government would reimburse local health authorities half the salaries of their medical staffs. The counties always had paid half the salaries of the district health officers. The act, therefore, gave the Government greater control over salaries, and committees were set up to fix salaries of medical and nursing staffs on a national basis. The employing and the staff sides could not agree. The health officers maintained that they and their assistants were specialists and should be paid the same as hospital specialists. The employers said:

Medical administrators' salaries should be similar to those of other professional administrators in the local government service, such as the finance officers, engineers, and architects. Local governments would have to increase substantially the pay of all their professional staffs if the doctors' rates of pay went up to the hospital scales and local governments could not afford it.

Many assistants in the health departments were doing medical work more analogous to that of the general practitioner than of the clinical specialist.

The dispute finally went to arbitration, and, by and large, the arbitrator agreed with the employers. Apart from the largest cities and counties, health officers' salaries are lower than those of clinical specialists, and those of assistant health officers and directors of bureaus are substantially lower than those of similar grades in hospitals. Salaries of the heads of the departments are based on the populations of their areas, although some discretion is given depending on the range of duties. It is only in the largest cities with populations over 600,000 that complete discretion as to the rate of pay is given. The staff side had felt that in small areas the employers could not be trusted to pay reasonable salaries unless they were forced to do so by the National Government but that in large areas the employers could be relied upon to pay enough to attract a good man. Many health officers received increases of pay as a result of the award, but the standard pay for new entrants to the service, which cannot be exceeded, is unattractive. The deputies of health officers receive two-thirds of the salaries of their chiefs.

The entrants to the service are supposed to have had at least 3 years of medical work after graduation and to have taken the diploma in public health, but many now, particularly those engaged in school health and clinic work, have had no specialized public health training, and are, therefore, ineligible for posts of health officer. More and more of those now entering the service are married medical women who use this as a method of augmenting the family income.

In my opinion, the salaries of medical officers of health are sufficient to attract good people, but unless the pay in the lower ranks is increased Great Britain will soon be short of men qualified to fill the senior posts.

Nonpolitical Appointments

A senior public health officer usually has done 2 or 3 years' hospital work after graduation—often he has also had a period of general practice. He has taken the diploma in public

health after a year of academic work at his own expense. He has entered the service as an assistant medical officer of health, doing school health, or maternity and child welfare, or chest clinic work. He has moved about the country, paying his own removal expenses, gaining experience in different fields and different areas, and has obtained, eventually, the post of medical officer of health of a small city or county. The posts are usually advertised, and he progresses to larger cities or counties, taking his pension rights with him.

The actual appointments are made by the city or county councils concerned, after interviewing selected candidates. Canvassing, direct or indirect—that is, the seeking of support by influence—disqualifies. Allegiance to any political party is frowned upon, and health officers take no part in politics, serving with equal loyalty any political party elected by the people.

The mayors of cities and chairmen of county councils are unpaid. They, too, are above politics during their term of office, which is usually for a year only. They are the social, and not the political, leaders of their communities and preside over the meetings of their councils.

The chief officers of local government, such as the health officer, report to committees of the council, and policy and finance are in the hands of these committees, the members of which are unpaid. The majority party appoints a "leader of the council" and the minority a "leader of the opposition." The town clerk or county clerk, a lawyer, coordinates the work of the various departments. He corresponds to a mayor or governor in the United States, except that he is nonpolitical; he does not decide policy or finance or make appointments—these are the functions of the elected members who operate through committees—and he remains in office until he goes to another area or retires on reaching the age limit.

Summary

1. Until World War II, the public health service in Britain was an attractive career, reasonably paid, and contained men who had the confidence of their councils and of the medical profession.

2. They had heavy responsibilities, including the administration of hospital services.

3. Since the National Health Service Act nationalized hospitals, there are no municipal hospitals under local control, and hospital clinicians receive better salaries than public health workers.

4. The fixation of rates of pay on a national basis has not been an unmixed blessing. The profession wanted fixed rates so that local governments would be required to pay reasonable salaries, but they wanted minimums only to be fixed. Arbitration of the issue fixed maximums as well, except for the chief health officers of the largest authorities. This has meant that some officers are not receiving as much as they would have received had the local government units been free to pay what they liked.

5. Some feel that, since the main problems of environmental hygiene have been dealt with and free medical treatment by general practitioners and hospitals is available for all, there is little for the health officer to do.

6. My own view is that, despite the undoubted contraction in some fields, there are new and important functions unfolding, such as looking beyond the confines of epidemic diseases, considering all forms of morbidity, and devising methods of reducing or preventing them. Preventive work should include methods of rehabilitation and aftercare, and the education of the public in such matters, for example, as the prevention of accidents in the home. Psychiatric illness and the problems of old age and chronic sickness must be tackled. Health officers also have important functions as liaison officers between the various branches of the health service, that is, the hospital and general practitioners' services. To be successful they must have good standing in their profession. All this is in addition to the duty of controlling the spread of infectious diseases for which a trained epidemiologist is essential.

7. In contrast with conditions in the United States:

The health officer is never a political appointee. He is a career officer who remains in office despite changes in local political power. Incidentally, a British health officer has security of tenure and cannot be discharged except with the concurrence of the National Ministry of Health.

Except at the London School of Hygiene, I doubt if the academic training of public health officers in Great Britain is as good as in the United States.

Even with the loss of hospital administration, the British health officer's range of duties in a local health unit is somewhat greater than in the United States. However, the combining of sanitary districts and participation in the work of the county are essential to attract and keep good men.

Trained health officers serve all parts of Britain.

When a British health officer moves from one authority to another, or to or from a university or hospital appointment, he takes his pension rights with him.

The British health officer is responsible not to one man, the mayor or governor as in the United States, but to the city council or county council as a whole.

Generally, there is a uniform standard of salary for similar posts throughout Great Britain.

8. The points of similarity are:

The senior posts, particularly in areas where there is continuity of service, are held by first class, experienced, and respected health officers.

There is a shortage of good candidates for the junior posts associated, in both countries, with inadequate pay, and due, in both countries, to linking rates of pay with those of other local government officers and not with those of other physicians.

Reported Tuberculosis Morbidity

United States, 1949-1951

By ROBERT J. ANDERSON, M.D., and HERBERT I. SAUER, B.A.

The effective and economical operation of a tuberculosis control program depends upon adequate knowledge of the extent and character of the services needed. One useful source of such information is newly reported tuberculosis cases—those cases which first become known to the health department—and the variations in some of their characteristics from State to State.

As with the other communicable diseases, the objectives of tuberculosis morbidity reporting are ordinarily considered threefold:

1. For protection of the health of the patient's family and the community.
2. For aiding in providing better care to individual patients.
3. For statistical and administrative purposes.

The last point is the primary concern of this paper. Our data are based on information from the semiannual tuberculosis reports, the National Office of Vital Statistics special report on notifiable diseases, 1947-50, and other reports provided by the various States.

Morbidity statistics may be used for a number of purposes, among them measurement of the extent of the tuberculosis problem and trends therein, the distribution of the disease, geographically and by other characteristics, and the success of the control program in reducing the problem, particularly the success of case finding. Figures on morbidity reporting are

sometimes used in apparently contradictory ways. For instance, increases in morbidity reporting may be interpreted as an indication of improved case finding, but decreases may be interpreted as an indication of decreased incidence or occurrence of the disease. Care must therefore be taken in interpreting morbidity reports lest unwarranted conclusions be drawn. The reasons for changes in reported morbidity cannot be ascertained from an examination of the figures alone. A knowledge of the actual operation of the control program and of some of the underlying conditions affecting reporting is necessary for interpretation of the data.

New Cases Reported in 1951

The total of 118,491 tuberculosis cases newly reported in the United States in 1951 (that is, reported for the first time) is slightly less than that for 1950 and represents a decline of 13.0 percent from the 1947-48 high. The decline in the rate of new cases reported per 100,000 population was 17.8 percent: from 94.0 in the 1947-1948 period to 77.3 in 1951.

The decrease in numbers of tuberculosis cases newly reported in the United States during the past several years has not been uniform for all States (table 1). Eleven States showed increases in the number of cases reported in 1951 as compared with the 1947-48 average, while the remaining States showed decreases. Several of the States showing increases were among those with low levels of reporting in 1947-48. Sixteen States, the District of Columbia, and the Territory of Hawaii showed decreases of more than 20 percent. For most of the States

Dr. Anderson is chief of the Division of Chronic Disease and Tuberculosis; Mr. Sauer is a statistician in that division.

Table 1. Tuberculosis cases newly reported, 1951, and percentage change from 1947-48 average, United States, each State and Territory

State	New cases reported 1951	Percent change as compared with 1947-48 average
Total, continental United States.....	118, 491	-13. 0

Hawaii.....	551	-58. 8
Puerto Rico.....	6, 075	-11. 7

showing major changes, the increase or decrease appears to be due in part to changes either in administrative procedures or in the extent of X-ray and other case-finding activities in the State.

Factors Influencing Reporting

The level of morbidity reported is influenced by three broad groups of factors:

1. The number of new cases developing during the year, together with the number of unknown cases existing at the beginning of the year.

2. The success of efforts to find these cases.

3. The completeness of reporting diagnosed cases to the health departments and the types of cases which are included in compilations of morbidity by those departments.

Changes in numbers of cases reported from year to year and variation from area to area may be due to changes or variations in any one or a combination of the above factors. These factors will be considered in reverse order in relation to the 1947-51 data.

There are variations among the States in the types of tuberculosis cases which are reported. In some States—for example, California and Massachusetts—the usual practice is to count active cases only, while some other areas include in their counts cases of borderline significance. Such differences in procedures have been described (1) and recommendations have been made and adopted by the State tuberculosis control officers (2) for further improving the usefulness of morbidity reporting in tuberculosis, particularly for counting the active and probably active cases separately from other reportable cases. Available information indicates that as much as one-fourth of the decline from 1947-48 to 1951 may be due to the decreases in the reporting of arrested cases.

Completeness of reporting also varies from area to area. While it is a truism that 100-percent reporting is ordinarily impractical it is possible to approach completeness. For example, in some areas more than 90 percent of persons dying from tuberculosis are reported cases prior to death, while in other areas only about 50 percent of these deaths are so reported. Those communities reporting practically all of

their cases prior to death are more nearly approaching complete reporting than those which report only half of tuberculosis decedents as living cases.

Examination of morbidity figures by source of report shows that reports from all major sources declined in the period under consideration. It would not therefore appear that changes in completeness of reporting from any one source would account for the 13-percent decline in reported cases from 1947-48 to 1951.

Efforts to find cases have apparently not fallen off in the United States as a whole since 1947 (3). In fact, the number of X-rays taken in case-finding programs in 1951, although less than in 1950, was 2½ million more than the annual average for 1947-48. In some States, however, changes have occurred. For some, more extensive case-finding activities have resulted in increases in the number of cases found. For a few States, the decreases appear to be due, in part at least, to less extensive case-finding activities. For example, the District of Columbia had a community-wide survey in 1948 which resulted in an unusually large number of new cases being reported; the number of X-rays taken in 1951 and therefore the number of new cases reported in that year are substantially below the 1947-48 level, although they are still above the average for the United States.

Since other factors will apparently thus account for only a relatively modest portion of the decline in the total number of newly reported cases for 1951 as compared with 1947-48, it seems reasonable to infer that there has been a decrease either in the number of new cases of tuberculosis developing each year or in the number of unknown significant cases existing in the population, or in both.

In order to emphasize that it is the number of known cases that determines the amount of tuberculosis services to be furnished by the tuberculosis control program, it must be mentioned that there does not appear to be any appreciable decline in the number of known cases of tuberculosis. This is probably due to two factors: With more extensive case finding in recent years, a higher proportion of the cases are known; and with improved therapy patients are living longer.

Cases per Death

Case finding and reporting have been generally recognized as essential steps in tuberculosis control. If the number of cases which occur were known, the completeness of case finding and reporting could be measured by the ratio of cases found and reported to the total cases occurring. Obviously we do not know how many cases occur and are undiscovered, so the number of deaths from tuberculosis has been used as an index of the occurrence of the disease. The ratio of cases reported per death has therefore been used rather generally to measure the relative extent of case finding and reporting.

The ratio of newly reported cases per death has risen from approximately two per death in 1941 to four new cases per death in 1951, and has risen steadily every year since 1947 (table 2). Improved case finding and reporting appear to be responsible for a part of this increase, although the decline in mortality has played a large part. For purposes of comparison, all the following computations of the ratio of new cases per death have been based upon the average number of tuberculosis deaths for the latest available 3-year period by State, that is, for 1947-49.

Table 2. Newly reported tuberculosis cases, cases per death, and rate per 100,000 population, United States, 1947-51

Year	New cases reported	New cases per death	New cases per 100,000 population
1947-----	135, 118	2.8	94.2
1948-----	137, 192	3.1	93.9
1949-----	134, 865	3.4	90.8
1950-----	121, 636	¹ 3.6	80.4
1951-----	118, 491	¹ 4.0	77.3

¹ Based upon tuberculosis deaths estimated by NOVS from 10-percent sample.

It must be remembered, however, that this ratio is affected by the case fatality rate, varying inversely with it; the higher the case fatality rate, the lower the case-death ratio and vice versa. That is, as more patients recover instead of dying, the ratio will be higher. Thus, further stress is placed upon the desirability

of a high ratio of new cases per death, indicating better case finding and reporting and/or lower case fatality. In some instances, however, variation in case-death ratios are due, in part at least, to variations in reporting practices.

Table 3 shows the 1949-51 averages of newly reported cases by State, together with the ratios of new cases per death. The 3-year average has been used to minimize fluctuations due to the effects of mass X-ray surveys, changes in reporting practices, and other variables. For the various States, new cases reported per death range from 1.8 to 6.5, with an average of 2.9 for the country as a whole. The northeastern States tend to have lower ratios than do other areas (fig. 1), while the 11 western States as a group have higher ratios, as do also the central States along the northern border of the country. There is, however, a substantial variation in the ratios from State to State within each region.

Race and Sex

During the period under study, the tuberculosis death rate among nonwhites was approximately three and one-half times the rate among whites. In view of this marked difference, it is important to consider differences by race in cases reported. The 1949-51 summaries of newly reported cases by race and sex for 46 States and the District of Columbia show rates per 100,000 population (1950 census) as follows:

	Total	Male	Female
White.....	71.7	90.5	54.6
Nonwhite.....	179.1	203.9	153.9

Thus the rate of newly reported tuberculosis cases among nonwhite persons was approximately two and one-half times that among white persons. In both groups the rates are higher among males than among females.

The latest 3-year period for which complete mortality tabulations are available by race and sex is 1947-49; using these mortality data, the ratios of newly reported tuberculosis cases per death, by race and sex, are:

	Total	Male	Female
White.....	3.2	2.9	3.8
Nonwhite.....	2.2	2.2	2.2

¹ 1947-49 average number of tuberculosis deaths.

² Population sources: For continental United States—July 1, 1950, Bureau of Census reports. For Territories—Apr. 1, 1950, Bureau of Census reports.

Figure 1. Tuberculosis cases newly reported per death, United States, 1949-51.

The high ratio of new cases reported per death for white females may mean that case finding and reporting are more effective among them than among white males, or it may be due to the fact that white females have lower death rates than do white males. Information from specific communities indicates that both factors are of importance.

Because tuberculosis is known to be more frequently fatal among nonwhites and because arrested tuberculosis is less frequently discovered in surveys among this group, one would expect to find a lower ratio of new cases per death in nonwhites than in whites. It is difficult, therefore, to compare case finding and reporting among nonwhites with that among whites on the basis of case-death ratios.

The ratio of new cases reported per death for each race varies from State to State (table 4) and from region to region, as is seen in the following summary table.

Region	New cases per death	
	White	Nonwhite
Northeast.....	2.3	2.4
South.....	3.8	1.9
North Central.....	3.4	2.6
West.....	3.5	3.0
Total.....	3.2	2.2

For whites, the South has the highest ratio of reporting; the Northeast the lowest. For nonwhites, the West has the highest level of reporting; the South the lowest. The Northeast has a slightly higher ratio for nonwhites than for whites, while the West and North Central States as a group have a ratio of reporting for nonwhites approximately four-fifths as high as for whites. The ratio of new cases per death for nonwhites in the South is only half that for the whites. Part of the explanation of the lower ratios of reporting for nonwhites may lie in the practice of reporting probably inactive cases and the generally recognized smaller number of arrested cases among nonwhites.

¹ From semiannual tuberculosis reports only, excluding cases with race not specified. The sums of white and nonwhite cases by State are frequently not identical with the latest available totals presented in table 3.

² Based upon latest available 3-year average of deaths by race, 1947-49.

³ Ratios not computed for States having fewer than 50 nonwhite tuberculosis deaths in the 3-year period.

⁴ 2-year average.

Fourteen States and one Territory had ratios of four or more new cases reported per death for whites, while only one State and one Territory had a ratio this high for nonwhites. Wisconsin, California, New York, Pennsylvania, and Alaska had slightly higher ratios among nonwhites than among whites. It would thus appear that the latter group is possibly placing greater emphasis upon their program of case finding and reporting among nonwhites than among whites.

Source of Report

The source of the report of cases was available for 44 States and the District of Columbia for the period 1949-51. During this period,

private physicians reported about 51,000 new cases or 15 percent of the total (fig. 2). Idaho was first in the proportion of new cases reported by private physicians with 71 percent, while Montana was second with 53 percent. Other States in which more than 30 percent of cases were reported by private physicians were Utah, North Dakota, Oregon, Minnesota, Kentucky, Kansas, Nevada, and Wyoming.

Forty percent of the new cases were reported by chest clinics (fig. 2) and 24 percent by general hospitals and tuberculosis hospitals combined. In some areas, private physicians refer substantial numbers of tuberculosis suspects to chest clinics for completion of clinical study and diagnosis. A low percentage of reports from physicians and a correspondingly high

percentage from clinics should not therefore automatically be construed as evidence of poor cooperation from physicians.

Reporting of tuberculosis by mental institutions has not improved appreciably. For the period 1949-51, less than 3 percent of all new cases were reported by mental institutions, although 8 percent of tuberculosis deaths occurred in such institutions. In spite of a decrease in the number of States which report no tuberculosis cases, or practically none, from mental institutions, there were still a dozen such States in 1951. It is possible that the tuberculosis cases were all diagnosed and reported prior to admission of the patients to mental institutions and that no cases developed while in these institutions. Information from other sources, however, indicates that limited case finding and reporting are more important factors. There is also the possibility that the cases reported by mental institutions are counted as coming from hospitals and other sources. Whatever the explanation, it would seem that the health departments for States with practically no tuberculosis reported from mental institutions are not receiving information needed for directing their tuberculosis control programs in these institutions.

Approximately 11.5 percent of newly reported cases were from sources classified as "Other and unknown"; most of these reports were from Veterans Administration, other Federal agencies, and from notifications of patients moving into one State from another State.

As was mentioned above, there was a decline in cases reported from each of the major sources from 1947-48 to 1951. Cases reported by hospitals declined 11 percent; by clinics, 16 percent; and by private physicians, 30 percent.

New Reporting Procedures

The need for more uniformity in tuberculosis morbidity reporting has been described elsewhere (1) and in a preceding paragraph reference has been made to the new reporting recommendations adopted by the State tuberculosis control officers and sanatorium directors (2). On the basis of these recommendations, the annual and semiannual tuberculosis reports requested by the Public Health Service

from each State and Territory have been revised, effective January 1952. Seven States (Arizona, Arkansas, California, Iowa, Michigan, Oklahoma, and Rhode Island) and the

Figure 2. Source of report of new tuberculosis cases, 1949-51.

District of Columbia provided data on the number of newly reported tuberculosis cases for the year 1951 essentially in accord with the new plan, while Nevada and Tennessee provided such data for the last 6 months of 1951. One State explained that the decline in new cases reported in 1951 was largely due to the application of the new recommendations. In this group of States, approximately three-fourths of the cases reported were active and probably active (group A) cases. The proportion of active cases varied from less than half in one State to practically all cases in another.

We feel that the State tuberculosis control officers and State sanatorium directors are to be

Meetings were held with each village and city council in the threatened areas and recommendations made concerning control measures. No attempt was made to gloss over the inadequacies of existing methods of control. Inevitably, one or more members of each council would urge that strict quarantine measures be enforced as a means of combating the spread of the disease. In one instance, despite advice to the contrary, officials of a village saw fit to oil all ditches, spray the entire village with DDT, and install sewer tile where open drainage ditches had previously existed in order to satisfy public demand for "positive" action. Needless to say, this village did accomplish things—improvements in sanitation. The fly and mosquito population was reduced in a dramatic manner, and sanitary nuisances associated with sewage disposal were effectively reduced in number. But the progress of the poliomyelitis outbreak was not appreciably affected by these "positive" measures. One of the village officials, who was antagonistic and suspicious of the health department recommendations, became their ardent defender as a consequence of information received at Akron Children's Hospital, where his wife had to be taken—a victim of poliomyelitis. Proclamations issued by the mayors of the cities and towns had a very positive effect on the diffident attitude of many adolescents toward control measures.

Adversely affected by the extensive publicity given poliomyelitis in the newspapers and over radio and television stations were local resorts,

recreational areas, and commercial establishments. One resort owner suffered a 70 percent loss in his summer's business as a result of cancellations. A groceryman was boycotted by his apprehensive customers and forced out of business when his son (and business partner) contracted the disease. Parents were reluctant to engage cottages or let their children attend camps. Plant managers and labor leaders were discouraged from holding picnics at a popular resort in Medina County by employees who feared the consequences of taking their families to large gatherings. Hundreds of telephone calls were received by the departments of public health from anxious parents and frightened individuals who became alarmed over newspaper headlines concerning the prevalence of poliomyelitis in this area. Scores of picnics were canceled, despite statements from the departments of public health that no great hazard existed. Persons living in the Cleveland and Akron areas wanted assurance that they would not contract poliomyelitis as a result of driving through the two counties.

Combating Public Fears

Editors of local newspapers did a remarkably fine job of combating public fear and apprehension through common-sense editorials. Some of those which received wide comment were titled, "Keep Cool, Watch for Polio Symptoms," "The Common Sense Approach," "Don't Fear Polio, Avoid Panic Is Local Physicians

Poliomyelitis morbidity and mortality, Wayne and Medina Counties, 1942-52

Cases of poliomyelitis reported in Wayne County, Ohio, 1922-52.

Advice," "Precautions Urged When Polio Has Struck," and "Other Diseases Worse Than Polio." An especially fine editorial, which appeared in the July 11 issue of the *Seville Chronicle*, deserves mention:

Heard Any Good Rumors Lately?

Fear itself is a frightening thing. When you aren't sure what you fear, it becomes hysteria. When persons who really have no fear use the hysteria of others to avoid social and community obligations which have become bothersome, it is little short of criminal.

Yet we have seen children confined to their yards, and public gatherings canceled; we have seen local families shunned because of vicious and unfounded rumors—all because of a mass hysteria about polio. But, as this is being written on Monday, there has not been a single case of poliomyelitis reported in Seville, in Guilford Township, or in any child attending Seville school. Compare that with the rumors you may have heard!

Polio can strike here, but a fear-inspired quarantine which, taken to its natural and insane conclusions would last not just this summer but into the next, and the one after that, and abolish attendance at church and school, will not stop it. Give your child a normal, happy, healthy summer. Observe sensible health precautions . . . and punch anyone in the nose

whom you hear spreading more rumors. You owe it to your children.

Finally, remember, the above advice is written, not by a disinterested observer, not by a misguided publicity seeker, but by the father of an only child, fortunate in that his work enables him to know his child during all her waking hours, vulnerable in his affection for her. And our little girl is going to lead a normal life, maybe learn to swim this summer.

The Medical Profession

When it became evident that poliomyelitis was getting off to an early start with the prospect of an epidemic by midsummer, conferences were held with the presidents of both county medical societies. On recommendation of the district health commissioner a special meeting was called on June 20 to which members of both medical societies were invited. Three prominent speakers outlined the clinical and epidemiological characteristics of the disease. A follow-up memorandum sent to all practicing physicians urged early reporting of cases; in addition, consultation was offered physicians with difficult cases. Questionnaires sent at intervals to practicing physicians

revealed that 72 percent have seen cases or suspected cases of poliomyelitis during the outbreak.

Local physicians in both counties voluntarily agreed to postpone tonsillectomies during the epidemic. The majority heeded the health department's admonition with reference to the inadvisability of immunizing children against diphtheria, whooping cough, and tetanus. With one possible exception, there have been no cases which could possibly be attributed to this procedure.

Several prominent physicians reported that they were literally "swamped" with apprehensive patients who were sure they were victims of poliomyelitis. There is good reason to believe that a large segment of the population under 15 years of age experienced symptoms which might very well be attributed to an abortive form of the disease. A few physicians observed physical findings which, from a clinical point of view, indicate the possibility of mixed infections. From an epidemiological standpoint, it appears that the outbreak in the southeast section of Wayne County was caused by a less virulent virus than that which attacked residents in the northwest section and which later spread to Medina County. The possibility of Coxsackie virus invasion of cases in the southwest section of Medina County seems plausible in view of clinical observations.

Special Studies

Mention has already been made of the invaluable help received from local chapters of the National Foundation for Infantile Paralysis. Another service rendered by that organization was the securing of a research team of experts from Yale University School of Medicine. Two staff members of the section of preventive medicine spent nearly a month in the two counties, obtaining blood and taking throat and fecal swabs of children who were close contacts of cases. This was done for the purpose of studying virus content and obtaining information as to the strain of virus involved.

Supplementing this aspect of the program were epidemiological studies by the staffs of each county department of public health, and an intensive series of studies by members of the

Ohio Department of Health. The initiation of these studies, which are still in progress, had a tremendous impact on the populace in the affected areas. It apparently satisfied the desire of many people for "positive" measures to control the disease. In truth, it was all we had to offer.

Staff Problems

As the disease progressed and public anxiety mounted, a greater proportion of staff time had to be devoted to problems arising from the outbreak. Clerks had to be briefed concerning the answers to typical questions. The volume of telephone calls and visits to the office by information seekers rose to unprecedented numbers. A bulletin board recording the number of cases became the object of public attention as the totals continued to mount. Members of the nursing and sanitation staff were interrogated wherever they made their appearance. Unaware of the real source of the disease, many apprehensive and possibly vindictive householders made complaints with reference to insanitary conditions existing on their neighbor's property. The demand for testing of water samples rose nearly 30 percent.

Shortage of nurses and inability to obtain new staff members during the epidemic posed a serious threat to other public health activities. The maternal, infant, and child health programs had to be practically abandoned, and the tuberculosis clinic in one county had to be closed. The fear of contracting poliomyelitis among adults was practically as great as the fear of contracting tuberculosis, perhaps due in part to the extended publicity given cases and deaths of adults. The local chapters of the National Foundation for Infantile Paralysis tried in vain to recruit volunteers for a "polio lift" to assist parents and afflicted children who required transportation to a hospital for physiotherapy. Whether from fear of the disease or lack of time, it is a fact that few persons offered their services.

School Problems

Several weeks prior to the opening of the schools in September, a memorandum was is-

sued to all school administrators in both counties outlining a course of action with respect to the opening and conduct of the schools in the presence of an outbreak of poliomyelitis. Principles laid down were in accordance with the recommendations of the Ohio Poliomyelitis Advisory Committee and the National Conference on Recommended Practices for the Control of Poliomyelitis held in Ann Arbor, Mich., in June 1949. These bodies, it will be recalled, recommended that schools be opened at the usual time and that they remain open during the course of an epidemic. To justify delaying the opening of schools in those areas where the disease was still rampant, authority was secured from the boards of health in the counties to declare school districts critical areas. Only four school districts, however, were so designated.

But, despite the announced policy of the boards of health to favor opening of schools on September 3 except in these four areas, public opinion, as expressed by parent-teacher associations and apprehensive alarmists, succeeded in forcing boards of education to delay the opening of all schools in both counties for 2 weeks. Although it is too early to ascertain whether the course of events will justify the stand taken by the boards of health, it is plain that public opinion overwhelmingly favored a delay in the opening of the schools. The public is not quite ready, it seems, to accept the advice of health authorities on this point largely because of our repeated admonition to parents that their children "avoid crowds" and "unnecessary contact with persons other than their usual associates."

Camps, Carnivals, and Fairs

With few exceptions, boys' and girls' camps were avoided by parents of children in both counties. Standard advice by the Ohio Department of Health to parents and camp directors concerning the desirability of keeping camps open had little effect on anxious parents who visualized each child with poliomyelitis as a permanent cripple.

Several prominent organizations had to cancel contracts with carnivals for summer appearances largely because of public pressure.

Poliomyelitis cases by week of onset, Wayne and Medina Counties, Ohio, 1952.

So great was the fear of poliomyelitis that the county fair boards of both counties decided against holding a fair. It was the first time in 103 years that a fair had not been held in Medina County.

Hospitalization and Rehabilitation

Although provision of hospital facilities for the care of poliomyelitis cases does not ordinarily fall in the category of public health administration, it is of utmost importance that public health organizations and hospitals work together in ameliorating the problem. Since the treatment of poliomyelitis is a specialized task requiring the services of different types of medical specialists and special equipment, only well-equipped hospitals can meet such emergencies. Fortunately for residents of Wayne and Medina Counties, the Akron Children's Hospital accommodated all patients sent there by local physicians.

As patients were discharged from the hospital, it became apparent that a serious deficiency existed in the over-all program. Parents were failing to return afflicted children to the hospital for physiotherapy. In Wayne County this situation had been anticipated, and, with

the help of funds from the National Foundation for Infantile Paralysis, it was possible to increase the time of a physiotherapist in the county sufficiently to cope with the increased demand for her services. At a joint meeting held at the Akron Children's Hospital September 5, it was agreed to set up treatment centers in Wayne, Medina, and adjacent counties where patients discharged from the hospital could receive the treatment indicated by the Akron physician in charge of the case. Once a month after release the child is to be returned to the hospital for a review of his case. This plan of decentralization is being tried; it remains to be seen whether parents will cooperate any better now that the travel involved has been effectively reduced.

Aggressive Educational Program

Every health department confronted with an epidemic of poliomyelitis finds itself the object of criticism by well-meaning but ill-advised "experts." Public opinion as expressed by these individuals can be damaging. In our opinion the best defense against such individuals and the half-truths which they occasionally succeed in getting before the public is an aggressive educational program. While it is plainly evident that our best efforts at informing the public concerning desirable procedures did not always succeed, we are convinced that, had we not done so, the results might have been still more hazardous.

It has been aptly said that every poliomyelitis epidemic comprises actually two diseases, poliomyelitis and hysteria. It takes a strong personality to tell the public, in the face of increasing numbers of cases, that medical science has not yet devised an effective control program, and the capacity of a field general to face a room full of hysterical parents and tell them to lead a normal existence during the progress of an epidemic.

With a few possible exceptions, the public has cooperated unusually well with the public health officials. Village and city officials have also given excellent cooperation. Despite the fact that a county-wide quarantine was invoked in a neighboring county, the boards of health in Wayne and Medina Counties have shown no inclination to do likewise. Instead, they have supported the contention of the health officer that responsibility for the spread of the disease rests primarily on the shoulders of parents. Child contacts have, however, been uniformly quarantined by health department officials for a period of 7 days from the last exposure.

Of considerable interest in this particular outbreak has been the extent to which the people have subscribed to poliomyelitis and hospitalization insurance. Approximately 50 percent of all hospital admissions in both counties were covered by poliomyelitis insurance; approximately 15 percent had hospitalization insurance. By virtue of this situation, the burden of the National Foundation for Infantile Paralysis was appreciably lessened.

Conclusion

The modern department of public health has a very real job to perform in meeting the problems of a poliomyelitis epidemic. Through the medium of community organization, it can alert the public to the nature of the disease and the available means for combating it. Public health workers must be prepared to assume the initiative in formulating a community-wide program; they must also be prepared to accept the responsibilities and the criticisms that go with the establishment of the program. Finally, it should be emphasized that control of poliomyelitis, including treatment and rehabilitation, is a cooperative enterprise, involving a host of agencies, all of which are essential in a successful program.

Ideas

Maplewood Dental Plan

MAPLEWOOD, N. J. How to handle a small number of dentally indigent school children without the overhead of a full-scale dental clinic is the problem.

Solution. The school medical department refers all cases of suspected or alleged dental indigency to the public health nurse who investigates the family's eligibility for dental care according to a family income scale approved by the New Jersey Dental Society. Children of eligible families are then referred to any one of the 16 local dentists of their choice, all of whom participate in the plan. The dentist, after inspection, estimates the work needed and its cost at a stipulated hourly rate. Upon approval of the estimate by the health officer, the dental work is completed, and the dentist is paid from funds provided by the Maplewood Service League, a women's civic organization.

Advantages. The plan's cost is a small percentage of the cost of maintaining clinic facilities. The plan eliminates any stigma of indigency which may be attached by some to clinic attendance. It encourages the children to continue going to the dentist of choice when their parents can again afford the service. It encourages parents who plead inability to pay, but who are ineligible under the plan, to provide overdue dental care at their own expense.

The plan was developed by the Maplewood Health Department, the board of education, and the local dental society.

Small Mobile Unit

MISSISSIPPI. A mobile unit has been designed, weighing 7 tons instead of the original 11 tons, to reach remote areas in the State for chest X-ray surveys when bridges on second- and third-class roads will not

carry the weight of the larger mobile chest X-ray unit.

The Mississippi State Board of Health purchased a 2-ton truck chassis with cab and had the body constructed to meet essential requirements for its X-ray equipment. The truck with the body complete, as shown in the picture, cost approximately \$4,000, and is considerably more economical to operate and maintain than the older and larger mobile unit.

The inside measurements are: width, 7 feet, 1 inch; length, 13 feet; height, 6 feet, 4 inches. Doors for entrance and exit are both on the right side (as in the larger unit) and are 26 inches wide. There are two built-in steps and one removable step for each door. The body has an inside lining of half-inch plywood. The floor has a plastic covering which carries a 15-year guarantee, does not require waxing, and is not sensitive to oil.

The equipment is arranged to provide a suitable desk for the clerk near the entrance at the rear of the bus and ample room for the technician to perform his duties.

Union's Health Circuit

PENNSYLVANIA. The mobile health survey program of the International Ladies' Garment Workers' Union brings the services of a permanent health center to outlying shop units.

The service was developed over the past 5 years by Dr. James Bloom, medical director of the union's health and welfare department for central and western Pennsylvania. It is a variation of the multiple health screening technique.

A team of two medical technicians, carefully trained in the taking of medical histories, make the rounds of scattered units of the union's con-

stituency. One is a medical case worker, and the other is a clinical laboratory technician. Together, they interview and test 10 to 12 workers daily. Union members are interviewed at their factories in private rooms set aside for the purpose. No physical examination is given, however.

Laboratory tests include: blood pressure, pulse rate, urinalysis, complete blood count, and additional determinations of sedimentation rate or blood sugar, if advisable. Visual adequacy is determined by a telebinocular apparatus.

Historical and laboratory reports are evaluated by the medical director, who reports significant findings to the worker's family physician. Reported participation is good—from 68 to 81 percent of workers in 89 shops. At the completion of two circuits, more than 13,000 patients had been seen, 5,338 significant abnormalities revealed, and 762 physicians contacted.

The program, with its emphasis on skillful interviewing for medical history, supported by laboratory values, has placed a large number of persons with previously unrecognized disease under medical care and, at the same time, has conserved medical manpower.

Sanitation Self-Rater

SAN DIEGO, CALIF. Owners and managers of eating and drinking establishments can determine whether they are providing their employees with essential guidance and materials.

A self-rating form has been devised by the local public health department to give conscientious supervisory personnel an opportunity to check themselves on their own attitudes, policies, and sanitation practices.

Not an inspection form and not for rating the performance of other personnel, the self-rater is intended solely for the supervisor. It covers the training of personnel, provision of adequate materials and suitable equipment, delegation of authority, provision of wholesome food, adequate utensil sanitization, and effective vermin and rodent control.

Looking Ahead of 1952

By PAUL Q. PETERSON, M.D.

Every health officer has two broad areas of responsibility. The first is primarily medical in nature and requires the diagnosis and treatment of the medical ills of the health officer's patient—that patient being the total community of people residing in the health district which the health department serves. The second responsibility is primarily administrative and requires the ability to organize and supervise personnel and facilities necessary to achieve the integrated health program which is planned for the health district.

In the practice of medicine an error in diagnosis and therapy by the physician jeopardizes the health and welfare of the individual patient. The health officer's mistake in diagnosis and therapy may jeopardize the health of hundreds of individuals and the welfare of an entire community. Therefore, from the standpoint of our first responsibility, we in public health must attempt to foresee the future public health needs of our patient and prepare programs that anticipate the changing disease problems facing our health district.

In the area of administration, the business executive who makes mistakes measures his failure in terms of reduced earnings. The public health officer's mistakes in the administrative field are measured in sickness. Therefore, the health officer must at regular intervals take stock of the abilities and efforts of the individuals engaged in the various programs. He should also attempt to anticipate changing social and economic problems.

Dr. Peterson, assistant director of health of the Ohio Department of Health, presented this paper before a meeting of the Ohio Public Health Association at Columbus, May 28.

This entire process represents what we in public health term as evaluation of the programs of our departments. For the most part the information, knowledge, and ability to achieve this objective rests within the hands of the local health officer. However, because of the complex nature of disease and of our social order, the local health administrator must draw upon sources of information which are broader than those available within his health district.

There are some significant trends which the Ohio Department of Health believes will create an impact on local health problems and therefore should be taken into consideration by the local health commissioners in planning services and programs for the protection of the public health in the years to follow.

Civil Defense

Probably no public health program has presented greater problems than civil defense. It is a situation in which none of us is really intimately familiar with the extent of the problems we will face. Although we have a broad background of experience in many of the areas, we are not completely sure of how the entire program should be developed to the best advantage. Also, we are faced with a public reaction which has been particularly frustrating. The attitude of many citizens ranges from complete indifference to hysteria, depending upon newspaper headlines and announcements which come from Washington. Because of indecision, there is also a state of confusion which has made it practically impossible to plan intelligently.

We feel, however, that the picture is clear enough at present for concrete action by community leaders who have true ability and honest

interest. State planning appears to be on a sounder basis, and for the first time real progress may be anticipated. This now places on the local health departments and health commissioners the responsibility of putting the program into effect.

Two important facets in the planning stage are of particular interest. The first is a plan for taking care of casualties that might be expected should an attack occur on one of the target areas in the State. This plan will specify what each community will be expected to do. It will make possible specific planning in the local community for a particular program without needless concern for problems which probably will not come to that locality. As this program is developed each local health department will be kept informed and the State department will depend upon it to provide this service.

The second program being completed is that of medical stockpiling of supplies and equipment. Ohio has participated with the Federal Civil Defense Administration in purchasing supplies which might be needed and has sent lists of those items to each health commissioner. The items are now being received and will be stored in strategic locations.

Drugs which require professional supervision will be located in hospitals surrounding the target areas and will be available for transportation to areas of need. Items which require only normal storage will be strategically located in the State, available for ready transportation to communities needing help. We recognize that there is an insufficient quantity of such equipment to satisfy the complete needs of the State. However, when it is remembered that this equipment will supplement supplies purchased by the local communities of Ohio and that local and State supplies will be complemented by Federal equipment, we may feel more secure that these essential items will be available when needed.

We would therefore alert the health commissioners of Ohio to the fact that the ensuing year will require of them a greater interest in problems of civil defense and that their medical administrative ability will be sorely needed if this program is to be successful.

Financing

The period of Federal support for basic local health and State health programs is ending. Within the past two fiscal years the total grants-in-aid allotted to Ohio for public health has been reduced by nearly one-half million dollars.

<i>Fiscal year</i>	<i>Grants-in-aid</i>
1950-----	\$1, 951, 883
1951-----	1, 944, 361
1952-----	1, 842, 002
1953-----	1, 561, 324

This reduction has created serious fiscal problems for both the State and local health departments. However, it may represent a blessing in disguise. Without a sound method of financial support which comes primarily from State and local sources, it is impossible to build the type of public health service in this State which can develop according to its particular needs and have sufficient financial stability to encourage long-range planning.

Added to this reduction of income, local departments are faced by mounting costs of service and the necessity of competing for their share of the tax dollar. Under a difficult tax structure, which cannot possibly provide funds necessary for all local governmental operation, it becomes absolutely essential that public health administrators devise a more stable financial structure for public health and the most efficient basic organization that can be recommended to the citizens of the State to insure the greatest return in service for the tax dollar provided to the health department.

Personnel

Because of the expanding horizons of public health and scientific research, which are giving us new methods and greater knowledge, the public health worker must have high standards of professional qualifications. No longer is our service primarily a police action. It is founded upon an educational approach for the application of scientific principles which will reduce the health hazards of the communities we serve.

The inclusion of a wider range of scientific disciplines and individuals of varying abilities requires the health commissioner to engage in

more serious planning so that the varying abilities of staff members may be integrated to best advantage. Constant in-service staff training should be established, for unless the health commissioner makes available to his staff new knowledge and techniques the programs will certainly suffer.

A second major problem in this area of personnel is that of shortages. We are all painfully aware of this problem because of our inability to fill many positions which have been budgeted. From studies made in Ohio and the country as a whole, we may anticipate continued shortages in qualified medical, nursing, and sanitation personnel. It is therefore necessary that we use the qualified talent at our disposal to best advantage and seek out ancillary personnel who may be useful.

Programs

We have heard much in the past about new programs. Especially, we have been urged to develop programs in the chronic disease field. These requests are proper because a larger population group is living in the age span in which these diseases take their toll. Community resources need to be marshaled and applied to these problems.

My main concern has been that too often we hear the statement, "The acute communicable diseases are now whipped. Public health must look for new fields to conquer." Nothing could be further from the truth. We may state flatly that we are not doing as well as we can with our present knowledge. There is an absolute necessity for better application of existing programs which have proved of value. Diseases for which immunization and other protective measures are available may, by judicious application of these procedures, be eradicated. We should not be satisfied with a decrease in their incidence and prevalence but should continue to apply with ever-increasing effort our control procedures with the aim of complete eradication of these maladies.

It must also be remembered that when we create artificial controls, usual host parasite relationships are altered so that we must maintain constant vigilance and control efforts. Should we fail, we will have created a popula-

tion susceptible to unprecedented rises in both incidence and prevalence. Diseases which fall in this category are: smallpox, typhoid, diphtheria, whooping cough, venereal disease, tetanus, and tuberculosis.

Another need in communicable disease control is for additional exploration in two areas:

1. We should investigate new control procedures for diseases about which we have amassed considerable knowledge but which are obviously not responding to present methods. For example, it may be that in brucellosis the emphasis on economic rather than on public health needs for control has been misplaced. Or in rabies our concern with the animal reservoir rather than the epidemiology of the disease in animals may be misdirected. Or in poliomyelitis our interest in the patient rather than the reservoir of infection may be a fallacy.

2. We must investigate public health hazards presented by diseases where these problems have not been clearly delineated in the past. For example, a recent epidemic of psittacosis among workers in poultry processing was traced to turkeys, a heretofore unknown reservoir of infection. Recent work has already shown that such diseases as histoplasmosis, toxoplasmosis, leptospirosis, and amebiasis may present dangers to public health which have not yet been appreciated and against which no adequate control programs have been formulated. Continued investigative effort and an open mind for the acceptance of new information and procedures by those actually administering programs is an essential need.

Two concurrent movements are making it necessary for the health commissioners of Ohio to enlarge their horizons:

1. It is apparent that Ohio is experiencing a ground swell of public interest in public health. More people on the street are becoming interested in public health programs and are willing to offer more support than ever before in the history of our commonwealth.

2. Public health as a field of official service is receiving ever-growing responsibilities. New programs are constantly being requested, and the talent of the health department is being

recognized because more and more legislative bodies are planning these programs under the administration of public health departments.

Thus, it is becoming evident that we may not permit our thinking to be stultified nor our programs to be stereotyped. We must adopt the philosophy that we are responsible for the total health needs of our communities and must be constantly planning to use the facilities within our districts in order that these community health problems may be brought under control.

I say quite sincerely that the local health departments hold the key to success of public health in Ohio. Either we are progressive, energetic, and intelligent enough to meet our

problems in a scientific and efficient manner completely divorced from personal considerations or public health will fail to retain public respect.

The interest of the public and their desire for service is unquestionable. If we have vision, dedication to service, and the courage to move ahead, our profession will prosper and our rewards will be many. If, on the other hand, we fail to accept this challenge because of lack of vision, personal interest, or a lack of courage, then we may be assured that ahead of 1952 lies a dismal prospect with diminishing public respect, limited budgets, and ever-decreasing responsibilities.

Court Rules Against Hoxsey Clinic

The United States Court of Appeals for the Fifth Circuit, sitting at New Orleans, on July 31, 1952, ordered the district court to enjoin Harry M. Hoxsey and the Hoxsey Cancer Clinic of Dallas, Tex., from shipping from the State their two colored liquids intended for use in the treatment of cancer. This reverses the decision of the District Court of the United States, Northern District, Dallas Division (Dec. 21, 1950), which refused to grant an injunction.

After reviewing the testimony of 50 physicians and pathologists and 5 nationally known cancer specialists who had testified for the Government and about 25 defense witnesses, the appeals court in a unanimous opinion found that the conclusions of the lower court were not supported by the evidence and that these Hoxsey "remedies" do not cure cancer. The court made these two pertinent rulings:

"... when the subject of investigation is the existence of cancer, the personal testimony of the lay sufferer is entitled to no weight, since the overwhelming preponderance of qualified opinion recognizes that not even the experts can assuredly diagnose this condition without the aid of biopsy and pathological examination."

"... despite the vast and continuous research which has been conducted into the cause of, and possible cures for, cancer the aggregate of medical experience and qualified experts recognize in the treatment of internal cancer only the methods of surgery, X-ray, radium, and some of the radioactive by-products of atomic bomb production."

The drugs in question originated about 1840, it was testified. One contained a laxative and potassium iodide and extracts of prickly ash, red clover blossom, and alfalfa; the other was chiefly of lactated pepsin, a flavoring used to disguise the unpleasant taste of potassium.

Psychiatry in Medical Education

The concentration of medicine during the past 75 years on the conquest of infectious diseases, on the science of bacteriology, and on the contributions of physics and chemistry to biology has tended toward a medical view of man as an isolated biological unit.

A somewhat similar isolationism accompanied the recent accelerated growth of psychiatric knowledge. In the efforts to establish diagnostic techniques, there was a tendency to equate the patient with the symptoms and patterns of behavior accompanying his illness. Concentration on the work of defining, limiting, and clarifying meant that, for a time, psychiatry, too, developed as a compartmentalized medical discipline and lost sight of the simple fact that the patient is a unique human being, a person subject to a variety of physical and emotional ills.

Following the tradition of Adolph Meyer and William Alanson White, forward-looking psychiatrists have long been pointing to the need to return to the main stream of medicine and reintegrate knowledge about psychic and somatic factors. They recognize that few patients fit into the classical clinical patterns of mental illness and that, to treat the patient, all factors affecting the personality of the individual must be considered. In this, physical complaints are as important as emotional factors.

Dissatisfaction with the fragmented view of the patient has grown with the realization that, to be effective, medical treatment must do more than concentrate on the disease entity. The whole person must be treated. Consideration must be given to factors of personality and behavior which influence and are influenced by physiological condition; consideration must also be given to the environment of the person under treatment. The effect of interpersonal relations and cultural forces on the individual must not be overlooked.

The medical profession is, in a sense, "rediscovering" what historically has always been the goal of medicine—to treat the person as well as the disease. Psychiatry, as a branch of medicine, is serving as the catalyst in bringing about the changes required by this "rediscovery," for "nothing that is human is foreign to psychiatry." Its particular focus gives psychiatry a strategic role in the movement of medicine toward dealing with the patient as a person.

The Practicing Physician

The conference reemphasized the social responsibilities of the physician. It was agreed that the community has a right to expect the physician to perform his functions with an understanding of the individual patient's emotional and social problems—that the community has a right to expect preventive medicine.

The physician has obligations to his patient's family and his patient's environment as well as to his patient. Problems related to child growth, the aged, chronic illness, and problems related to the supply of physicians require thought and action by both the community and the profession of medicine. The physician must be aware of the contributions of professions other than that of medicine. He must work with members of those professions if his own contributions are to be most effective.

A major purpose of psychiatric teaching is to prepare the physician for his most effective contribution to the community by providing a cross-fertilization between medical science and social science with emphasis on the importance of understanding people as human beings. The concept of the physician and the patient as total persons in a total environment involves a humanistic even more than a medical approach.

The growing trend in modern medicine toward a reemphasis of the need to treat the patient as a whole person was pointed up sharply in the Conference on Psychiatric Education held at Cornell University, Ithaca, N. Y., in June 1951.

Organized and conducted by the American Psychiatric Association and the Association of American Medical Colleges under a grant from the National Institute of Mental Health of the Public Health Service, the conference formally stated its purpose as the promotion and preservation of the health of the community "by investigating, defining, and helping to develop programs which will improve the teaching of basic and clinical psychiatry; by advancing the medical skills needed to recognize and treat

mental illness and emotional maladjustment; by coordinating the efforts of all groups concerned with these problems so that their total resources may be used most effectively."

The recurrent theme throughout the conference, as contained in its report published in June 1952 by the American Psychiatric Association under the title of "Psychiatry and Medical Education," was the role of psychiatry in the development of integrated medical teaching. The main lines of discussion, with emphasis on public health implications, are summarized here on the basis of the published report.

Dr. Seymour D. Vestermark, author of the summary, is chief of the training and standards branch of the National Institute of Mental Health and was a participant in the conference.

Integrated Medical Education

It was suggested in conference discussions that psychiatry could lead in coordinating medical teaching in some areas. One area is that of the physician-patient relationship, basic to all of medicine. The department of psychiatry should be responsible for this teaching area because of its special insight into the dynamics of interpersonal relations. But special attention would need to be given to integrating the department of psychiatry with the other departments in the medical center.

Similarly, another area in which psychiatry can be helpful—interviewing and history taking—presents problems which stress the need for integrated administration and cross-fertilization among the different departments of the medical school. Case histories written by psychiatric residents tend to lack critical medical information, whereas case histories written by medical residents tend to bypass emotional attitudes and unconscious factors. It was suggested that the kind of interdisciplinary program needed to teach interviewing and history taking should be supported and developed by frequent communication among faculty members and between students and faculty.

Research Opportunities

For psychiatry, one of the broader implications of a rounded medical education is the

continuing need and opportunity for research to validate the empirical body of knowledge acquired through clinical practice. The conference recognized the value, for medical instruction in psychiatry, of the body of knowledge derived from intensive treatment of patients whose symptoms are classifiable. But to prevent teaching from becoming mere indoctrination, it is essential that clinical knowledge be supplemented by related research, such as animal studies, investigations into the physiological and biochemical components of emotional health and emotional disturbances, and controlled experiments on the role of the learning process in psychotherapy.

On the other hand, the emphasis of psychiatry on the social aspects of medicine has far-reaching implications for a redirected program of medical training. Current thinking that emotional maladjustment has its roots and first manifests itself in early childhood points to the need for integrating the study of pediatrics and psychiatry, and for including the subject of growth and development in undergraduate medical instruction in psychiatry. Many medical schools are experimenting with courses in growth and development taught jointly by the departments of pediatrics and psychiatry. This is but one example of how the complex nature of social influences on physical health and disease might better be taken into account.

Psychiatry thus opens the door for contributions from the social sciences.

Human Ecology and Human Personality

A significant portion of the conference was devoted to discussing the need for including study of human ecology and human personality in the medical curriculum. Predicated on the assumption that to fully understand an organism it is essential to understand the organism's environment, the study of human ecology would include material from social anthropology, psychology, and sociology. This material, together with material drawn directly from the field of psychiatry on human personality and on human ecology, would complement the study of human biology in the medical training program.

In listing some of the more important components of the study of human ecology and personality, the report of the conference groups topics under four major headings. Those areas of personality closely related to the study of physiology include perception, learning, emotion and motivation, and language and thought. The study of normal child behavior, and of adolescence, maturity, and senescence constitute the segment of human ecology concerned with the genesis and decline of complex human activities. The third grouping—the nature and development of personality, and the study of individual differences—is followed by a fourth grouping devoted to society and culture—the family, the interaction of personality and culture, and the forces contributing to social organization and disorganization.

Coordination

The task of incorporating such broad areas of knowledge into the medical curriculum presents some major problems. While instruction must be focused on the primary goal of producing adequately prepared physicians, it must also be designed to fit all the related parts of medicine into a coordinated presentation. A special group will need to be organized whose function it will be to insure effective teaching of human ecology and personality. This means adding to the faculty physicians with training

in the social sciences and social scientists who have had experience in a clinical setting. Together, these teams might be able to cooperate on research projects and join forces in coordinating medical teaching.

The conference report indicates that currently there is a growing tendency toward integrative teaching in medical centers—sometimes involving cooperation with departments in other schools of the university. Most schools also are attempting to include instruction in psychiatry in all 4 years of the medical curriculum. Since psychiatry is linked with the practice of medicine generally and, in particular, with such areas of medical practice as pediatrics, internal medicine, endocrinology, and neurology, and since it must take into account social, cultural, and environmental considerations, it can serve as an excellent means of integrating the fragmented approach of medicine and of bringing medicine closer to the social sciences and related disciplines.

In considering techniques that might be used for integrating instruction, the conference placed much emphasis on methods which fit into the framework of a patient-oriented approach to medicine. Such methods include clinical clerkships, around which all clinical teaching in undergraduate medical school is developed, and the newer method of preceptorships in which students work directly with physicians in general practice. Also, the assignment of students as family medical advisers will enable them to see patients in their natural habitat and to gain first-hand knowledge about the chronic illnesses and the social aspects of illness.

The Future Physician

Consideration of the patient-oriented approach to medicine raises questions which prompt a reevaluation of the physician's role in society and of the kind of person the physician might ideally be. In addition to his specialized responsibilities, the physician has an opportunity to function as a leader and should be sensitive to the issues and problems of his community and to the people in it. The medical school recognizing this is paying increasing attention to the development of the medical stu-

dent both as a mature individual and as a well-qualified member of the medical profession.

In any list of the assets which the future physician should bring with him to medical school, the factors indicating success in interpersonal relationships are of extreme importance. Some critics question whether current admissions policies result in the selection of students who are potentially most capable of fulfilling the responsibilities of socially oriented physicians as well as of scientists.

The conference, in addition to pointing out the loss of good students through restrictive admissions policies and artificial quota systems, strongly urged the need for a shift in emphasis in selection criteria. The current emphasis on scholastic grades places too great a premium on preparation in the basic sciences, on interest in things rather than in people, without sufficient regard for the personal and social aspects of medicine.

It was suggested that a psychiatrist be included on the admissions committee of a medical school to help in the interviewing and the selection of students. It was also suggested that the medical school faculty confer frequently with the advisers of premedical school students to interpret to them the need of the future physician for broader areas of knowledge and understanding.

The emphasis on the medical student as a well-rounded individual with a liberal college education, an individual aware of his responsibilities to society and sensitive to the pressures and problems of his fellow citizens, carried over into the conference discussions about the general nature of medical education. Personality growth, stimulation of thought and action on the part of students, and close faculty-student relationships were stressed as primary goals of medical education.

Creative Teaching

The trend away from didactic instruction and toward freedom for the student to express doubt and criticism is further complicated by the increasing difficulty of imparting the full fund of current medical knowledge in a 4-year course of study. The almost overwhelming

amount of knowledge the medical student must now acquire intensifies the natural anxiety he experiences as he begins to realize the responsibilities he is assuming as a future physician. The aim of medical training, therefore, must be to develop insight into the principles, and skill in the application, of working methods.

Medical school teaching provides the opportunity for a creative kind of teaching. In building the medical faculty, more consideration should be given to teaching ability as well as to research and clinical interests. To provide the student with a milieu in which he can develop his interests, acquire knowledge in a coordinated fashion, and at the same time gain experience in dealing with human beings, the individual faculty members, the various departments, and the administration of the medical school must pool their resources—philosophical, scientific, and professional—as well as those of personnel, equipment, and space.

Solution

In conclusion, the conference report emphasized that "the techniques of teamwork and group action extend beyond cooperative work with physicians. Many of the problems cited . . . cannot be solved by caring for the individual patient or family but must be approached on a community-wide basis. The physician's work must more and more be integrated with the broad program of preventive medicine and maintenance of health. This is so because the skill and knowledge required for the mastery of major problems of 'social engineering' exceed the resources of the individual physician. Knowing his limitations, he must be able to assess the resources of other groups and to join in teamwork for community betterment, contributing his special skills and knowledge about stress and illness, and recognizing the contributions of other disciplines."

In the light of what psychiatry has already learned about how people function and how psychic, somatic, and social factors are inextricably interrelated, the integrative force of psychiatry and medical education should be a force for better mental and physical health.

—SEYMOUR D. VESTERMARK, M.D.

Psychology, Mental Health, and Aging

Highlights of the papers presented during the fifth Annual Scientific Meeting of the Gerontological Society in combined session with the division of maturity and old age of the American Psychological Association are given here. The conference was held in Washington, D. C., September 5-7, 1952.

Conference Report

Need New Intelligence Criteria During Maturity

Intelligence does not decline with early maturity, according to Raymond J. Corsini, M.S., Wisconsin Department of Public Welfare. This is in contradiction to the classic findings of Wechsler, who maintains that every human capacity after attaining a maximum begins an immediate decline.

Mr. Corsini reported on studies made on 1,072 inmates of San Quentin prison. Ten of the subtests of the Wechsler-Bellevue Adult Intelligence Test were given to the group, which included 172 men past the age of 60. This is the largest number of older people studied on an individual test. In comparing his findings with those of Wechsler, Mr. Corsini noted that for both groups performance ratings drop off, but with respect to verbal abilities the combined trend for the San Quentin data is to rise from 15 to 55 and to fall from that point on, while Wechsler's verbal average holds fairly well to about the age of 40 and then falls. From Wechsler's data it appears that there is little difference in the amount of general cultural knowledge of people 15 and 55. From his data Mr.

Corsini reported that the 55-year-old people appear to have more cultural knowledge.

Must Define Intelligence

Among his conclusions, Mr. Corsini noted that when age is a factor in the correlation of each subtest with the whole test, the tests measure other things besides intelligence, such as visual and auditory acuity and motor speed. He said further that we cannot discuss intelligence and aging unless we know what is meant by both terms. He suggested that a distinction be made between intelligence as a "within-the-skin concept of mental ability" and "intelligent behavior."

Mr. Corsini questioned the wisdom of measuring intelligence by items variously affected by age. The single best item in terms of measuring intelligence which is least affected one way or another by age appears to be immediate memory as measured by the digit span test, he said.

In the discussion which followed the presentation of this paper, Dr. David Wechsler, psychologist of the Bellevue Psychiatric Hospital, and "father" of the Wechsler-Bellevue Intelligence Tests, said that new criteria are probably needed in order

to assess factors governing intelligence. It is probable, he said, that different kinds of tests should be applied at each 5-year age level since the same kind of tests could not measure the intelligence of an infant as well as that of an older person.

Rorschach Test Taps Personality Facets

"Although the usefulness of the Rorschach in a clinical setting has been well established, the validity of the technique is not so unequivocal as to be taken for granted by the experimental clinician," stated Charles Wenar, Ph.D., of the Institute of Psychosomatic and Psychiatric Research of the Michael Reese Hospital, Chicago. This is especially true when it is used on populations which previously have received relatively little attention, such as aging individuals.

Dr. Wenar reported on studies of 20 subjects between the ages of 55 and 65, all members of a class titled "Making the Most of Maturity." Psychological and psychiatric examinations were given and the members' social adjustment was recorded

by a trained observer in the class. Good Rorschachs were defined as those which revealed emotional richness and stable control. Two types of deviations from health were an overemphasis on emotion, and an overemphasis on control.

Need Behavioral Observations

Dr. Wenar found a high, positive correlation between Rorschach and psychiatric ratings and a low, positive correlation between Rorschach and social ratings, and between psychiatric and social adjustment ratings. He interpreted this as meaning that the Rorschach can be used as a valid measure of the general intactness of the personality structure of the aging individual, but it is of only limited usefulness as an index of the constructiveness of the individual's behavior in a social situation.

The Rorschach, like a psychiatric interview, can tap many important facets of the personality, but it would be naive to think that it can cover the entire behavioral repertoire of the individual. A further implication, Dr. Wenar said, is that in order to get as full a picture of the person as possible, such abstract or "depth" techniques should be supplemented by behavioral observations in real life situations.

Elderly Often Wrongly Thought Psychotic

Many elderly people who are thought to be mental patients are placed in a mental hospital when their condition may be due to extreme excitement and confusion, nutritional deficiencies, overmedication, alcoholic intoxication, or emotional hysteria, reported A. J. Tuttle, M.D., of the Hillside Home and Hospital, Bridgeport, Conn. He found in a study of cases sent in for commitment to a State mental institution only 20 percent were truly psychotic.

At the Hillside Home there is a detention unit in which these patients were observed 3 days or more. Of 93 cases, only 18 were committed to the mental institution. In 75 cases, the diagnosis was in error.

With proper evaluation, classification, rehabilitation, and placement of the chronically ill, infirm, and the aged, further mental and physical deterioration can be prevented and some of the overcrowding of mental institutions will be alleviated, Dr. Tuttle said.

Oldsters in Homes Have Few Complaints

Contrary to normal expectations, men and women living in institutions have fewer complaints about their physical and mental health than those living in their own homes, according to Dr. Jacob Tuckman, Ph.D., Columbia University. However, women in institutions have more complaints than men. This may be due not to actual differences in mental and physical health in the men, but because institutional care tends to minimize their complaints. The women apparently do not react in the same way to institutional care and, therefore, have as many complaints about their health as their sisters living at home.

The decrease in physical and mental complaints among the older age groups is contrary to expectations because with age there should be an increase in susceptibility to disease. The findings suggest that symptoms may disappear with age because the threshold of pain may be higher or that older individuals accept more readily the cultural stereotype that poor health is a concomitant of aging, Dr. Tuckman felt.

In another study, Miss Vilma Olsvary, B.A., of the Mental Health Institute, Cherokee, Iowa, found that the residents of county homes in Iowa are a depressed, forlorn, and hopeless lot. These people are in

the homes because of physical or mental illness, or because they have no family to take care of them, but, mostly, because they have little or no money and have been ousted from their community. Seventy elderly residents of four of the county homes were surveyed. These included 47 persons classified as normal and 23 as slightly below normal. The factual psychological picture reported by Miss Olsvary is that these elderly people in the county homes are living in an inner and outward atmosphere of depression, loneliness, resignation, and social isolation.

These forlorn people resent being in the home and wish they were out, but few have plans for the future. In general they have a negative attitude toward themselves. The majority feel that the years under 40 were the most profitable and the happiest and the years since 40 the least happy, and that they can expect nothing of themselves or of society in their years to come.

Some environmental conditions have their influence on these psychological reactions, said Miss Olsvary. She did not discuss the question of whether the county home is the best solution for all these people.

Factors Influencing Behavior in Elderly

In spite of the effort and time required, it is important to attempt to recognize both the conscious and unconscious influences affecting behavior in elderly people, said Ewald W. Busse, M.D., division of psychosomatic medicine, University of Colorado Medical Center. Using a group of patients from the outpatient department of the Colorado Medical Center and a hospitalized group of patients from the wards of the Colorado Psychopathic Hospital, Dr. Busse and his colleagues inspected three major aspects of their lives: religious activity and feelings, sexual activity and feelings, and re-

High Points From Other Papers

Youth and Age

Modern culture views human growth with "top-sided" values and overemphasizes the importance of youth and physical ability. The result is that little place is found in a mobile and aggressive society, except by accident or fortunate circumstances, for individuals in the postreproductive phase of life.

—Maurice E. Linden, M.D., and Paul Douglas Courtney, Ed.D., Norristown State Hospital, Norristown, Pa.

Work and Retirement

We are a labor-rich economy and the older worker is only one in a number of marginal groups. We should beware against keeping older men employed at supervisory levels at the price of the frustration of younger capable men. Men do start to fail, some of them early, and there is a certain rigidity in their points of view.

—Eli Ginzberg, Ph.D., director, Project on Conservation of Human Resources, Columbia University.

Yardsticks for Retirement

In this country we seem to discount the values of experience, wisdom, and judgment, and worship the prototype of the business executive with his great drive, dynamism, and ulcers. Performance and productivity are the only yardsticks a company can logically use as criteria of employment and retirement, rather than merely the potential physical capacity as shown in a medical examination.

—L. S. Barrus, Cleveland Twist Drill Company.

Psychosis Factors

Education, occupation, and the extent of indulgence in alcohol seem to be factors related to the psychosis of cerebral arteriosclerosis. Few highly educated individuals and a preponderance of those with little education, few professional and white-collar persons and more laborers and craftsmen have this psychosis. It would seem that these factors in a patient's life history may represent poorer personality integration and thus lessened equipment with which to meet the challenge of a growing impairment.

—Robert M. Naiman, M.D., Brooklyn Veterans Hospital.

lation-ship with their children. He found that there is a definite shift of activity in religion. There is less participation in church and church functions although there is no change in belief in a deity. They felt that church attendance was not necessary, he found, since they are involved in little or no guilt producing behavior.

In the two groups interest in sex was not lost. Among women more than among men, sexual frustration is a very important anxiety producing factor in the aged.

The attitude and behavior of older persons in regard to their grown children, according to Dr. Busse, is largely unconsciously determined and represents the end product of a life-long series of events—largely influenced by dependency-hostility conflicts. A definite correlation between parental attitudes existing many years ago and the type of reaction now apparent between the grown child and the subject was found in the study.

Perceptual Clarity and Aging

Using the same group of subjects, Laurence L. Frost, Ph.D., attempted to correlate Rorschach findings with physiological changes in the aging process. The clarity of the patient's perception, as measured by the Rorschach test, was examined in light of the measured functioning of the vascular system, the excretory system, and the central nervous system. No significant relationships were demonstrated at this time in either the vascular or excretory systems; however, it was found that a significantly greater number of generalized abnormal electroencephalographic recordings were found in those subjects with a low perceptual clarity. Patients with electroencephalographic records indicative of focal disturbances showed no differences in perceptual clarity.

Dr. Frost concluded that the elderly individual has at least an even chance of presenting a normal electroencephalogram, and his chances

are nearly three out of four of having a high degree of perceptual clarity. If the pattern of the EEG is abnormal, the probability of his having a high degree of perceptual clarity becomes much lower, dropping to one chance out of two.

Four Roles

Of the Psychologist

Four distinct contributions that the psychologist can make in mental health programs concerned with aging were outlined in the symposium discussion by Sidney L. Pressey, Ph.D., professor of psychology, Ohio State University. The first contribution should be to determine and emphasize the potentialities as contrasted with the liabilities of the older years.

That retirement at 65 is arbitrary, cuts off the work life of many substantially short of their potentialities, and creates numerous problems of mental health is increasingly recognized. If there are types of work and service in which older people may have substantial and sometimes especial competence, it is the second contribution of the psychologist to find and define these jobs and undertakings, find and appraise the appropriate old people, and bring the two together.

The third task for psychologists is to develop needed inventories and tests which are as specifically planned for work with older people as the equipment of a high school counselor is specifically designed for work with adolescents. The tests for a 60-year-old should be appropriate to him. The building of tests for the older years presents one of the few remaining measurement frontiers, said Dr. Pressey. The effort should be to develop tests of the especial and most distinctive strengths of the older years—tests of carefulness, judgment, the seeing of many relations and meanings, tests of disinterestedness, tolerance, patience.

High Points From Other Papers

Mortality Trends

The outstanding effect of medical science in the past half century has been the tremendous increase in the chances for survival of the individual. In the period from 1920 to 1930, the rate of mortality of the white population remained the same in the age groups of 50 to 65, 65 to 75, and 75 to 85 years. In the period from 1930 to 1940 and again from 1940 to 1949, the mortality showed a significant decrease in these older age groups, except for white males aged 50 to 65 years. The trends of these mortality rates indicate that survival and longevity of older individuals or of greater numbers of individuals over 50 should continue to improve.

—William Hall Lewis, Jr., M.D.,
Memorial Center, New York City.

The Aging Eye

The ability of the eye to restore its normal function after being fatigued by prolonged light stimulation and then subjected to a psychosensory stimulation, such as touch, sound, or threat of pain, changes significantly with increasing age. These changes are greater between the oldest and middle-aged groups than between the middle-aged and youngest groups.

—Lillian S. Kumnick, Ph.D., and
Rev. Henryk Misiak, Ph.D., Department
of Psychology, Fordham University.

Flicker Frequency

The critical flicker frequency, the rate at which flashes of light give the appearance of being steady, decreases with age at the same rate as other sensory and motor functions. Thus, when a young and an old person are looking at a flickering light, for example television, the old person will begin to see the light as a steady one more quickly than the younger person.

—Neil S. Coppinger, Ph.D., Veterans
Administration Center, Wadsworth, Kans.

Brain Waves

The activity of the "brain waves" of older persons, as measured by the electroencephalogram, tends to become slower. Greater changes occur in subjects from 80 to 94 than in those from 65 to 80.

—Walter D. Obrist, Ph.D., Moosehaven
Research Laboratory, Orange Park, Fla.

The general acceptance of changes in common points of view regarding the aged will require a continuing vigorous program of public education. Here is the suggested fourth role of the psychologist. Courses in the psychology of the older years should be as common as courses in child psychology in college and graduate school. In fact, a beginning should be made earlier, such as in secondary school home economics courses in family living. There should also be more public school adult programs and extension courses regarding the older years. If public attitudes toward age can be constructively remade, then indeed a major contribution to mental health in age will be made, concluded Dr. Pressey.

Mental Health Needs And the Community

The theory that a society that fosters research to save life cannot escape the responsibility for that extended life defines the attitude of the health worker, said Paul H. Stevenson, M.D., of the National Institute of Mental Health, in a symposium on community mental health. Public health occupies an "exposed" position in relation to the problems of aging, he said. But for the reduction in the communicable diseases and other medical advances, problems of aging would not exist. The public health worker recognizes the problem as a cooperative one, involving a large number of community agencies.

One of the important contributions of public health is the investigation of the peculiarities of the illnesses of later age—heart disease, cancer, cerebral hemorrhage, nephritis. These are "Fifth Column" diseases; to be discovered early they must be searched for. The psychological implications of these diseases cannot be discounted, said Dr. Stevenson.

More psychological insights focus-

High Points From Other Papers

Blood and Oxygen Consumption

With increasing age (40 to 95) there is a gradual reduction in the amount of oxygen required by individuals under resting conditions, although older individuals vary a great deal among themselves. The reduction in basal metabolism is largely due to a reduced uptake of oxygen from the lungs of older people rather than a change in the amount of air breathed by the subject.

—Nathan W. Shock, Ph.D., and Marvin Yiengst, B.S., National Heart Institute, Public Health Service.

Less blood and oxygen go to the older person's brain than to the younger person's. Brain cells do not increase their utilization of oxygen, if the amount of oxygen going to the brain is increased.

—Joseph Fazekas, M.D., Gallinger Municipal Hospital, Washington, D. C.

During our lifetime the rate of perfusion of blood through the tissues becomes lower, but for the most part the greatest decrease occurs between the ages 18 to 25.

—H. B. Jones, Ph.D., University of California, Berkeley.

Chronic Disease

The various chronic diseases appear to have some correlation with each other and with age. Coronary thrombosis, diabetes, obesity, and hypertension occur with each other more frequently than would be expected by chance.

—Dean F. Davies, M.D., Washington University School of Medicine, St. Louis, Mo.

Life Span

The upper limit of life has not been reached. As long as people die from diseases or injuries, the only answer to the question of physiological or ideal life span in man is that it is yet to be determined. Even so, two-fifths of all deaths in the United States in 1948 occurred after the age of 70 and one-sixth to one-fifth after the age of 80, permitting us to assume that the upper limit of life is beyond these ages.

—Raphael Ginzberg, M.D., and Vilma Olsvary, B.A., Gerontological Unit, Mental Health Institute, Cherokee, Iowa.

ing on the individual are needed, Dr. Stevenson said. New testing procedures must be found and old-age guidance centers equipped to make medical evaluations. Practically all community services will tend to preserve and maintain the ability of aging people to utilize their capabilities, he concluded.

Research Possibilities

Almost Limitless

Oscar J. Kaplan, Ph.D. San Diego State Teachers College (California), closed the symposium with a discussion of research needs. He said we lack much of the information needed to design a community mental health program. We must recognize the complexity of the mental problems of the aged, for the aged often suffer from a number of different functional disturbances.

Research possibilities are almost limitless, said Dr. Kaplan, but research requires instruments. We need valid personality tests. Sample surveys may provide the tools for the study of mental health. We need more information on caring for senile persons in institutions, in old peoples' homes, and in the individual's home. We need to strengthen the bonds of the family.

Mental health depends upon physical health, home life, recreation, education, and economic security. Research in these aspects will help throw light on other problems of mental health. We need to inquire into the advisability of segregation of older persons. The en-

tire world is a laboratory, said Dr. Kaplan. We should study the peoples of the whole world to grasp the sociology of later life.

Aging is one of our greatest social problems, yet the mental disorders of later life are not inevitable.

Program Planning For the Aged

Basic to all programming is a thorough knowledge of facts, Miss Ollie A. Randall, consultant, Community Service Society, New York, maintained in discussing programming for the aged. Efforts to bring about changes in existing services, she told the symposium audience, are regularly frustrated by mild tolerance and overprotection, ignorance and indifference, and the strong resistance to facing up to the so-called horrors of old age on the part of responsible people in the community.

A major problem confronting program planners is that of achieving proper balance in fixing responsibility for seeing to it that old people have a "good life." The final decision as to what is "good," especially in old age, is a personal one for each member of society, said Miss Randall. She warned against too great an overemphasis on "the aged" as a group and the creating of a "profession" of being aged. Segregation of older people for the purpose of services designed for them could be a disservice of the very worst kind. It has become the custom to isolate them in "homes for the aged"—safely out of circulation, in

spite of the fact that more and more old people wish to remain in their own homes.

Older people want to go on working after they are no longer permitted to work full time, Miss Randall stated. Alternatives such as part-time work, or a different kind of work, or pensions present psychological difficulties to many older people. Social yardsticks must be revised, for work has a special meaning in our society. We shall never have a contented group of older people if they are assigned to a non-working role which robs them of their social and economic status.

Failures in programming for health and medical care and for providing suitable housing are blamed on high costs, the lack of facilities adequate in number or in kind, the shortage of trained personnel, and the lack of concern for older people of the community at large and the professional groups in particular. There is also lack of appreciation on the part of old people of their own needs and the possibilities for meeting them.

Miss Randall concluded that the solutions to the major problems in programming for the aged lie in education of individuals as to the worth and dignity of the human being. Once this philosophy of human values underlies and permeates all programming and it is understood that there is no place in a free democracy for rivalry between the young and the old for the good things of life, the problems which beset the aged and their fellow planners will not be solved, but the way will be opened for solution.

Illness and Health Services In an Aging Population

This collection of four papers was presented at a session of the Second International Gerontological Congress, held in St. Louis in September 1951. These, with other papers from the congress, appeared in brief in the February issue of *Public Health Reports* (pp. 127, 130, 136, and 137).

Now brought together in their entirety in a single volume, the four articles provide comprehensive analyses of quantitative data on illness and health services in an aging population and throw light on disabling illness as one of the complex and interrelated factors which make it difficult for many persons to achieve reasonable health and happiness in old age.

The papers are: "Health Status and Health Requirements of an Aging Population," by G. St.J. Perrott, Marcus S. Goldstein, and Selwyn D. Collins; "Illness Among Older People in Hagerstown, Maryland," by Antonio Clocco and Phillip S. Lawrence; "Experience of the Health Insurance Plan of Greater New York With Its Older Enrollees," by George Baehr and Neva R. Deardorff; and "Health Services for the Aging in Saskatchewan," by Leonard S. Rosenfeld, Frederick D. Mott, and Malcolm G. Taylor.

Illness and Health Services in an Aging Population. (Public Health Service Publication No. 170) 1952. 68 pages, tables, graphs. 23 cents.

Selected References on Aging. An Annotated Bibliography

This is a bibliographic selection of the most significant materials on the problem of aging that have appeared in the past several years. Compiled by the library of the Federal Security Agency for the Committee on

Aging and Geriatrics, the bibliography affords a quick reference for both the layman and the professional worker and covers the basic thinking to date in this field. The titles are grouped under six main headings: social aspects of an aging population; economic aspects of an aging population; medical aspects of an aging population; general references and conference reports; conference and group discussion methods; and bibliographies. The references are annotated briefly except where the title is self explanatory.

Selected References on Aging. An Annotated Bibliography. Federal Security Agency Committee on Aging and Geriatrics, Washington, D. C., 1952. 36 pages. 20 cents.

Diseases of the Heart And Blood Vessels

How important are diseases of the heart as causes of death in the United States? What types of cardiovascular disease are the chief killers? Has the death rate from diseases of the heart increased or decreased? Are race and sex important factors? What age groups are affected by these diseases? Have rheumatic fever and rheumatic heart disease deaths been going down? Do more people die in certain months or seasons of the year than in others? Is the Nation's manpower affected by diseases of the heart and circulation? How common is disability from these diseases?

The American Heart Association, in cooperation with the Public Health Service, attempts to answer the questions in a brochure which economizes on textual explanation but which accents the heart disease message through the skillful use of color in 12 statistical charts.

Usually, the most recent data included are for 1948, although in some instances 1949 and 1950 data are given. An example of the latter is a table showing the estimated number of deaths and death rates for specific diseases of the heart and

circulatory system in the United States, for 1950.

The charts are preceded by a short glossary of heart disease terms.

Diseases of the Heart and Blood Vessels—Facts and Figures. 12 pages. Single copies may be requested at no cost from the National Heart Institute, National Institutes of Health, Public Health Service, Bethesda 14, Md., and from the American Heart Association, 1775 Broadway, New York 19, N. Y. In quantity, order from the American Heart Association at \$15.00 a hundred copies.

for the general public

Whooping Cough

Although whooping cough is often considered a mild disease, its dangers, particularly to children under 3, cannot be overemphasized. This health information leaflet describes the disease, its characteristic cough, and how it is spread. Care of the patient—isolation, proper rest and diet—are covered. Prevention of whooping cough by means of vaccination of children, preferably when 6 months of age, is stressed. Booster shots, or reinforcing doses of vaccine when the child is ready to go to school are recommended.

Whooping Cough. Health Information Series, No. 60 (Public Health Service Publication No. 220). Reprinted 1952. 1-fold leaflet. 5 cents; \$1.25 per 100.

Publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication (including its Public Health Service publication number). Single copies of most Public Health Service publications can be obtained without charge from the Public Inquiries Branch, Public Health Service, Washington 25, D. C.

Three Studies on Domestic Rats and Murine Typhus Control

Studies on rats and their ectoparasites in relation to murine typhus control are reported in detail in three papers published as Public Health Monograph No. 5 under the general title, "Domestic Rats, Rat Ectoparasites, and Typhus Control."

Part I. Domestic Rats in Relation to Typhus Control. By Harvey B. Morlan, M.S., Bernice C. Utterback, and Jack E. Dent.

This paper reports the composition of rat samples and the prevalence of typhus antibodies in rats by species, sex, and age, together with observations on rat behavior and reproduction. It includes information for students of rat ecology, and strengthens conclusions indicated by the gross data in previous articles.

The rat samples were divided into groups based on body length, weight, species, sex, and age. Roof rats (*Rattus rattus*) and brown rats (*Rattus norvegicus*) collected from one untreated and two DDT-dusted Georgia counties were studied, in both field and colony situations. A shake-down method of hand-catching rats proved to be a valuable supplement to usual trapping methods. Questioning occupants of premises being surveyed and using records of captures in relation to the number of traps set proved to be unreliable methods for estimating relative abundance of rats.

Sex ratios in the two rat species and the average body length of sexes within each species were similar. Samples were slightly biased in favor of large rats.

During three full operational years, complement fixation tests for murine typhus were completed for 18,959 rat serums. The average titer

Morlan, Harvey B., Utterback, Bernice C., Dent, Jack E., Wilcomb, Maxwell J., Jr., Griffith, Melvin E., and Ellis, Leslie L.: Domestic rats, rat ectoparasites, and typhus control. Public Health Monograph No. 5 (Public Health Service Publication No. 209). U. S. Government Printing Office, Washington, D. C., 1952. Price 25 cents.

level of positive serums from brown rats was consistently higher than that for serums from roof rats when species from two of the counties were compared. There were no regular differences between prevalence of antibodies between rat species; prevalence was similar in male and female rats; antibodies were more prevalent in adult rats than in young rats and in larger than smaller body length or weight groups.

Reproductive capacity in both species tended to be proportional to body length. Data suggest two peaks in the seasonal level of reproduction, the greater centered about March, the lesser about August.

An observed tendency of brown rats to supplant roof rats in parts of the study area raises an interesting question of possible effects on typhus epidemiology.

Part II. Ectoparasites of Domestic Rats in Relation to Typhus Control. By Harvey B. Morlan, M.S., and Bernice C. Utterback.

The extensive ectoparasite data collected during a study of murine typhus in southwestern Georgia are summarized in this paper. Observations on rats provided material for the preceding paper.

Four common species of ectoparasites, *Xenopsylla cheopis*, *Leptopsylla segnis*, *Bdelonyssus bacoti*, and *Polyplax spinulosa* made up 95 percent of the ectoparasites recovered from over 20,000 rats. Although *X. cheopis* is recognized as the principal vector of murine typhus, it appears desirable to investigate further the possible role of *P. spinulosa* as a supplementary vector of typhus among rats.

X. cheopis, *L. segnis*, and *P. spinulosa* infested higher percentages of brown than of roof rats, while the reverse was true of *B. bacoti*. Rats which were positive to the murine typhus complement fixation test were more frequently infested with *X. cheopis* and *L. segnis* than were negative rats. *X. cheopis* and *B. bacoti* normally infested young rats more frequently than

adult rats. Percentages of rats infested with *P. spinulosa* were higher for male than for female rats.

In the untreated county, infestation of all rats with *X. cheopis* occurred in only 29 percent of 705 instances of multiple catches from the same building on the same day.

During and subsequent to DDT dusting, rats infested with *X. cheopis* were found on 11 to 76 percent of the treated premises compared to 81 to 90 percent infestation of untreated premises. Apparently, DDT dusting was less effective for female than for male ectoparasites. Higher percentages of females of both *X. cheopis* and *L. segnis* were found on roof rats than on brown rats. In the untreated county, the proportion of females of *X. cheopis* increased in months with a lower mean temperature and decreased in months with a higher mean temperature.

Part III. Commensal Rat Ectoparasite Collections in Oklahoma. By Maxwell J. Wilcomb, Jr., M.S., Melvin E. Griffith, Ph.D., and Leslie L. Ellis, M.S.

The ectoparasite and typhus records from commensal rat collections in 33 Oklahoma counties from November 1949 through June 1951 are presented in this paper.

During the study 1,051 rats were collected. Fifty of these were roof rats; the remainder were brown rats. The roof rats were free of ectoparasites; 758 of the brown rats which were collected alive yielded most of the ectoparasites. Mites, lice, and fleas were identified. Of the mites, *Laelaps echidninus* was the most abundant species. *Xenopsylla cheopis* infested 11 percent of live Norway rats. Most oriental rat fleas were taken from food, feed, seed, or grain-handling establishments in industrial districts.

Twenty of the blood specimens from 675 rats were positive for murine typhus. Four *X. cheopis* were found on an infected rat from one county and an average of 6.1 *X. cheopis* from 19 typhus positive rats collected in another county.

Two Studies of Plague

Results of plague studies by the Rodent-Plague Investigations Group of Colorado and a plague-typhus control unit created by the Communicable Disease Center of the Public Health Service and the Texas State Health Department in conjunction with the South Plains Health Department are reported in Public Health Monograph No. 6, "Plague in Colorado and Texas."

Part I. Plague in Colorado. By Dean H. Ecke, M.S., and Clifford W. Johnson, M.A.

The Colorado studies had three major objectives: to locate and study sylvatic plague epizootics, to determine the possible role of domestic rats in plague ecology in Colorado, and to determine the possible dangers to human beings from plague.

The history of human plague in the United States, beginning with the first recognized case in San Francisco in 1900, and theories on methods of spread of the disease are reviewed. Although there have been no proved cases of human plague in Colorado up to the time of this study, the disease has been demonstrated among rodents in the State for nearly 10 years.

The studies, carried out by an entomologist and a mammalogist, centered in the Denver metropolitan area, with field work extending into 13 surrounding counties. The five major habitats in this area are described. Details are given of the methods, techniques, and equipment used in collecting rodents and their parasites. Whenever the collections were large enough to make computations reasonably accurate, statistical analyses were made to determine the monthly flea indexes for different species of rodents.

Thirteen species of Colorado mammals are listed, with information on their range, distri-

. . .

Ecke, Dean H., Johnson, Clifford W., Miles, Virgil I., Wilcomb, Maxwell J., Jr., and Irons, J. V.: Plague in Colorado and Texas. Public Health Monograph No. 6 (Public Health Service Publication No. 210). U. S. Government Printing Office, Washington, 1952. Price 30 cents.

bation, hibernation habits, fleas found on each species, and importance of each species of flea as a plague vector. Forty-one species of fleas are listed, with information on their host preference and medical importance. A check list of the wild mammals and their fleas encountered in this study is given in tabular form. Flea species are also listed according to species directly associated with primary reservoirs of plague in Colorado, species of possible medical importance (suspected of contributing to primary or secondary reservoirs), and species of no apparent importance in plague ecology as determined by this study. A table showing the locations of plague findings in Colorado counties from 1911 to 1949 is included.

Details of plague in Park County, Colo., are given, including history, effect of plague on rodents, plague-positive findings from field collections in the county, and an evaluation of rodent species and their fleas in regard to plague. A plague-like epizootic in Logan and Weld Counties is described.

Transmission of plague by nonrodent species—avian predators and scavengers, two mammalian predators, the badger and the coyote—and man's influence on the spread of sylvatic plague are discussed.

Methods used in making rat surveys in Denver and vicinity are described. Two maps of the area are included. The results of association of domestic rats with field rodents are discussed. Results of a survey of the rural rat populations around Denver are reported.

Means of human contact with plague in Colorado—direct contact with wild rodents, contact with plague-infected fleas from wild ro-

dents, and direct contact with domestic rats and their fleas—are described. It is concluded that direct contact with infected rodents is the most probable method of transmission of plague from rodents to man.

Part II. Rodent Plague in the Texas South Plains, 1947-49, With Ecological Considerations. By Virgil I. Miles, B.A., Maxwell J. Wilcomb, Jr., M.S., and J. V. Irons, Sc.D.

The history of plague in Texas is reviewed, the methods and procedures used by the plague-typhus control unit in nine counties in the Texas South Plains, and the type of soil, principal crops, climate, habitat types, and small-mammal species in the area are described and discussed.

Findings of campestral plague in the nine-county area are tabulated by county, date, type of material examined, number of fleas in each pool of plague-positive material, number of hosts, and location—by nearest town, direction, and airline distance from place of collection. Species of fleas and their mammal hosts, their numbers, and months in which plague was found in fleas or tissues, are noted.

Results are reported of a thorough study, from an ecological standpoint, of an area in which most of the habitat types and animal species common to the South Plains were well represented, together with a map, divided into cultivated and uncultivated zones, on which are indicated the prairie dog colonies in the area, and the relation of such areas to plague epizootics among prairie dogs.

Compulsory Smallpox Vaccination

—The University City, Missouri, Case—

By NEWELL A. GEORGE, LL.M.

A recent court opinion in Missouri upholding the validity of a compulsory vaccination regulation indicates this subject is still a matter of active interest.

On August 5, 1919, the Board of Education of University City, Missouri, adopted for the first time a compulsory vaccination regulation. The regulation was amended by the school board on February 7, 1929. Since the 1929 change, the regulation has provided:

No child shall be received into any public school unless he has been vaccinated against smallpox and evidence thereof sufficient in the judgment of the superintendent has been presented.

Court action to test the validity of the regulation of the University City Board of Education was filed in January 1952 by the parents of twin daughters. When their daughters were 5 years old the parents presented them to the public school and sought to enroll them in kindergarten classes. Entrance was refused when the parents would not permit their daughters to be vaccinated. The following year the parents again sought to have their children enrolled in the public school and their entrance was again refused. The failure of the parents to have the twins vaccinated and the refusal of school authorities to permit their entrance precipitated the filing of a misde-

meanor charge against the parents for violating the compulsory school attendance law of the State of Missouri. This criminal case was tried on an agreed statement of facts and the parents were acquitted.

On January 29, 1952, a mandamus action was filed in the Circuit Court of the County of St. Louis to compel the members of the Board of Education of University City to enroll the twin girls in the public school system or to show cause why they should not be so enrolled. It was alleged that the parents were resident taxpayers of University City; that they were the parents of twin girls, then 7 years of age; that the children had been presented for enrollment on numerous occasions; that enrollment had been refused for the reason that the children had not been vaccinated against smallpox; that the children had not been so vaccinated because such vaccination would have impaired their health; that there was neither an actual nor a threatened epidemic of smallpox in the area; that the refusal of the school board to admit the children was unreasonable, arbitrary and capricious, and constituted an abuse of discretion; that the parents were unable to pay to have their children educated in a private school; that the parents faced criminal prosecution unless the children were admitted; and that they were without an adequate remedy at law unless the court granted the writ prayed for.

The answer of the school board admitted many of the parents' allegations. The school board, however, denied that vaccination would impair the health of the children; denied that

Mr. George, regional attorney for the Federal Security Agency at Kansas City, Mo., is a member of the Bar of the State of Kansas and of the District of Columbia.

there was no actual or threatened epidemic of smallpox in the area; denied that the refusal of the school board to admit the children was unreasonable, arbitrary and capricious, or was an abuse of discretion; and denied that the petitioners were without adequate remedy at law.

The school board further stated that at all times when the children were presented for enrollment the school board had in effect a rule requiring all children to be vaccinated against the disease of smallpox, but that a child could be admitted to the public schools if the child's parents presented to the proper authorities a written statement, signed by a licensed physician, to the effect that vaccination would be injurious to the health of the child. The answer further stated that the rule in effect had the approval of city, county, and other authorities; that the disease of smallpox is very contagious and results in serious illness and frequently death or permanent disfiguration; that it spreads rapidly and is readily contracted by groups of persons; and that it has been the public policy of the school and health authorities to require all persons to be immunized against the disease by vaccination in order to prevent epidemics from spreading throughout the United States. It was prayed that the alternative writ be quashed and that the pre-emptory writ be denied.

Because of the fundamental legal, medical, and social questions involved in this case, the attorney representing the school board secured as witnesses experts qualified to present the clinical, laboratory, and epidemiological knowledge of smallpox to the court.

The case was tried in the circuit court of St. Louis, Mo., April 28, 1952. Since the basic facts had been agreed upon, the attorney for the parents of the twins took only one hour for his presentation. The attorney for the school board then called his witnesses, all of whom were specialists in public health or in related fields. Each physician testified regarding the deadly and devastating effect of smallpox and the rapidity with which it spreads. Once infection occurs in a community, they advised the court, a person could become infected and transmit the disease before he himself noted symptoms.

One physician, after qualifying as an expert

witness, testified as to the effect of smallpox upon the human body, the improbability of a cure without injury to the person, and that the best method known to medical science to lessen the liability to infection from smallpox is by vaccination. Thereafter, upon stipulation by counsel, each witness, after qualifying as an expert, was asked if his testimony would agree with that previously given. All answered in the affirmative.

After the last witness had testified, counsel for the school board summarized the testimony of the expert witnesses. He emphasized the point, made repeatedly in testimony, that, although there was no outbreak of smallpox evident in the area, the surest way of preventing one is by vaccination before it occurs. The trial was then adjourned.

One week later the judge of the thirteenth circuit handed down his opinion:

THE CIRCUIT COURT OF THE COUNTY OF ST. LOUIS

STATE OF MISSOURI, DIVISION No. 2

No. 194,776

STATE OF MISSOURI, EX REL., AND HENRY MOREY,
ET UX., REALTORS

v.

WILLIS REALS, ET AL., RESPONDENTS

Memorandum

"This is an action in mandamus brought by Henry Morey and Delma Morey, parents of twin girls now 7 years old, against the respondents, members of the Board of Education of the School District of the City of University City, to compel said school board to accept relators' children into the University City schools without vaccination against smallpox.

"In the petition it is stated that 'said children have not been vaccinated against smallpox for the reason that such vaccination would impair the health of the children.' No evidence was introduced to support this allegation and it is therefore no longer an issue in the case.

"The only issue remaining for determination arises as a result of the allegation in the petition 'That such failure and refusal on the part of Respondents to admit the said children of the

Smallpox cases and deaths in the United States, 1900-1950

Petitioners to the Public Schools of the City of University City, Missouri, is unreasonable, arbitrary, and capricious, and is an abuse of discretion on the part of Respondents.'

"It is uncontroverted that the schools of University City have an enrollment of more than 5,000 children, and that the school board now has, and for many years has had, a rule requiring all children to be, or to have been, vaccinated against smallpox before admitting them into the schools. It is also conclusively shown that there is not now any smallpox epidemic, nor any threat of such epidemic, in St. Louis County.

"The question for determination by this court is whether the rule requiring vaccination at a time and place where there is no epidemic or immediate threat of epidemic is an unreasonable requirement, or whether the school board in the exercise of a proper discretion may enforce such rule for the purpose of seeking to prevent such an epidemic from arising.

"The courts of our State have always recognized the right of the school boards of the

State to make reasonable rules for the regulation of their respective schools.

"Many years ago, long before the efficacy of vaccination as a means of prevention had been so generally accepted, Judge Rombauer in the case of *In re Rebenack*, 62 Mo. App., 8, said 'In the nature of things, it must rest with the boards of education to determine what regulations are needful for a safe and proper management of the schools, and for the physical and moral health of the pupils entrusted to their care. If such regulations are not oppressive or arbitrary, the courts cannot, or should not, interfere.'

"It is only in the case of an abuse of discretionary powers of a board invested with authority to regulate, that the court will undertake to supervise official discretion. How far the right to exclude one for the good of the many should be carried is also a question addressed to the discretion of the school board; and when that discretion is honestly, reasonably, and impartially exercised the courts should not interfere.

"In the trial of this case the court had the

benefit of the opinions of a number of outstanding specialists in the field of public health and the control of communicable diseases. It was their testimony, without exception, that while there is no known cure for smallpox, the remarkable reduction in the cases of that dread disease is attributable to the present general acceptance and the proven preventive effectiveness of vaccination, and that any relaxation of rules requiring such vaccination would to the extent of such relaxation increase the danger of the introduction of the disease into the schools.

"The doctor in charge of the Bureau of Communicable Diseases of the Missouri Department of Health testified that in 1937 there were 1,751

reported cases of smallpox in our State. From that year the number of reported cases dropped markedly and in the past 9 years the highest number of reported cases for any year was 11. Indeed he testified that in 1950 and 1951 only two cases were reported for each year.

"In the light of testimony so overwhelming and statistical information so convincing of the protective value of vaccination against this once prevalent disease, the court must hold that the respondents are wholly within the exercise of a sound discretion in adhering to their rule requiring vaccination of children in their school system."

John A. Witthaus, Judge.

High-Temperature Short-Time Pasteurization

16 mm., sound, black and white, 21 minutes, 1951.

Audience: Milk sanitarians and control authorities responsible for milk sanitation programs and policies.

Available: Loan—Communicable Disease Center, Public Health Service, Box 185, Chamblee, Ga. Purchase—Castle Film Division, United World Films, 1445 Park Avenue, New York 29, N. Y.

This film was designed to aid in training inspection personnel in the proper procedures for testing the functioning and accuracy of high-temperature, short-time pasteurization controls, in accordance with the regulations of the standard milk ordinance.

After stressing the fact that milk pasteurized by the high-temperature, short-time method is absolutely safe only if it is heated to at least 161° F. for a period not shorter than 15 seconds, this motion picture depicts the procedures, theory, and observations enabling a milk sanitarian to inspect, test, and understand the complex equipment that controls the

pasteurization of milk by this method. The main tests and procedures shown and explained are: (1) checking the accuracy of the indicating thermometer; (2) testing the functioning of recorder-controller and sealing adjustment in conformance with regulations; (3) seeing that the pasteurized milk pressure in the regenerator is higher than that of the raw milk; and (4) checking the accuracy of the diversion valve and calculating the duration of the holding time.

Biology of Domestic Flies

16 mm., sound, black and white, 9 minutes, 1952.

Audience: Professional, scientific, and technical personnel of health departments and other professional personnel engaged in or interested in community fly control.

Available: Loan—Federal Security Agency, Public Health Service, Communicable Disease Center, Box 185, Chamblee, Ga. Purchase—United World Films, Inc., 1445 Park Avenue, New York 29, N. Y.

This film, one of the community fly control series produced by the Communicable Disease Center, Public Health Service, supplies information on the habits of the most common varieties of flies in order to facilitate community fly control pro-

grams. The content of the film covers the following subjects:

1. Life cycle of the housefly.
2. The characteristics of domestic flies (houseflies, blowflies, fleshflies, and stableflies) compared and contrasted.
3. Typical breeding places and radius of areas of control and measures as determined by the flight range of flies.
4. Public health implications of the fly's mechanisms for transmitting disease organisms and filth. (Flies ingest only liquids. They regurgitate bacteria carrying liquids in order to dissolve and make available solid foods. They also deposit germ-laden excreta—fly specks—on food and other surfaces.)
5. Habitual fly resting places under varying conditions of time and weather and how familiarity with fly habits aids effective control through residual and space spraying with insecticides.
6. The development of strains of flies resistant to insecticides after a series of several spraying campaigns.

NOTE: Filmstrip No. F80, "Biology of Domestic Flies," 35 mm., sound, color, 9 minutes, 81 frames, released 1952, is also available for presenting the same material as is shown in this motion picture.

Psychological Impact of Cancer Surgery

By ARTHUR SUTHERLAND, M.D.

The problems involved in management of the cancer patient have been radically altered during the past few years by the striking advances in therapeutic techniques. Operative mortalities are being reduced to a minimum. Post-operative medical control has been vastly improved, and operations on patients who not so long ago were considered inoperable are now routine. Not many years ago, the long-term survivor of a cancer operation was considered a unique phenomenon, and therapeutic emphasis was centered on symptomatic management of the terminal cancer patient. Modern therapeutic methods have created an increasingly large army of survivors. It would seem that the problems of the cancer patient would be solved by his survival alone, but unfortunately this is not so. Advances in treatment, like all other advances, have created problems. Unfortunately, the extensive surgery which is necessary for the control of many forms of cancer results in major changes in form and function of various parts of the body. These changes are often disfiguring or mutilating and are not lightly borne by the average patient. They present challenges to his capacity for adaptation in all areas of living, and at times the problems created may appear overwhelming. The result is the therapeutic paradox of patients cured of cancer and clinically well who are able

to function only in a very circumscribed way or not at all because the methods necessary for cure have resulted in psychological invalidism.

Practical Management

Little systematic study has been done on the impact of cancer and the attending surgical procedures to guide the clinician and others associated with him in the practical problem of managing the postoperative cancer patient in his total situation. The Memorial Hospital in New York has established a group to study these problems. This group, consisting of psychiatrists, internists, psychologists, psychiatric social workers, surgeons, and nurses from the various clinical departments of the hospital, has found it advisable to concentrate its attention on certain types of cancer and certain classes of operation. Much of its information is highly particular and has to do with the specific problems met by each patient in the class of operation studied. Nevertheless, certain general conclusions can be drawn which apply to the whole field of cancer and, indeed, to any surgery where serious change in form and function of the body results.

Apparently much of the emphasis in current rehabilitation practices concerned with the psychological management of the patient with any sort of serious disability is misdirected. There seems to be a tacit assumption that the only real problem is the patient's belief that he has problems; therefore, therapeutic effort should be directed toward persuading him that he has no serious problems or at least to minimizing those he does have. This approach, even when fortified by all available clichés, is rarely effective because it is totally unrealistic.

Dr. Sutherland is an associate attending physician and psychiatrist at the Memorial Hospital, New York City. This paper was presented at the National Cancer Society's program, National Conference of Social Work, Chicago, May 27, 1952 (see Public Health Reports, October, p. 955).

The patient has very real, very immediate problems to solve which must be solved by him, alone or with the help of others. But solved they must be if the individual is to return to his previous ability to function and to emotional peace. It is when these problems are not solved that psychological invalidism occurs.

The approach based on the denial of the existence of problems has an underlying quality of contempt and condemnation for those patients whose problems will not be denied. It describes invalidism in terms of deterioration of moral fiber, of "loss of independence," and of "regression." It fails to recognize that retreat from function is the result of inability to master the problems created by the traumatic event, and that function is resumed when the problems are solved. As a matter of fact, the so-called loss of independence and regression are often necessary to the process of repair. They are to be accepted and not penalized in any way. They are in lieu of more serious disorganizations attendant upon attempts at function without the hope of mastery. The dictum "it's what's left that counts" is true as far as it goes, but it is at least equally true that the loss of a significant body part—an arm, a breast, a stomach, or a rectum—in the mind of the patient calls for a fundamental review of his ability to function normally.

Adjustment to Cancer

One cannot speak of "adjustment" to cancer because this concept is too abstract and general to be meaningful. Each patient must be considered as an individual with a particular type of cancer—an individual who has undergone a particular form of surgery or other therapy. In the first place, there is no special psychology of patients in whom cancer develops. Cancer happens to all types of people: people who are more or less "normal," people who have character neuroses—neurotics, psychotics, and psychopaths. It does not, as far as we know, select particular kinds of emotional problems. Moreover, cancer itself is not a uniform disease. It can vary from a basal cell carcinoma with almost no possibility of mortality to a highly malignant, rapidly growing tumor which can defy all methods of control. Cancer can necessitate the

removal of almost any organ in the body, organs which play varying roles in the total life adaptation of the patient. The necessary surgery results in a considerable variation in form and function of the affected organs. One cannot easily separate adaptation to cancer from adaptation to measures needed for its cure. In the vast majority of patients, the threat or fear of cancer is submerged in the problems of adaptation required by the extensive change in form and function produced by surgery.

Adaptations to these procedures are by no means static. Actually adaptations begin with the patient's discovery of something wrong with his health. They progress for better or for worse during the preoperative course, reach a culmination in the crisis of surgery, and then evolve during the postoperative and convalescent period towards the long-range, more or less final resolutions. Moreover, they are not at any time independent of concurrent life situations, but, on the contrary, both concurrent life situations and the patterns of adaptation fundamentally influence each other. Mrs. A., for example, has an abdominal colostomy, that is, an abdominal anus through which she must evacuate her bowel movements and over which she has no voluntary control. She accomplishes this by regular, repeated irrigations. For 12 years she was able to manage these irrigations with almost no spilling and was able to work regularly. But when she came into conflict with her daughter, she developed uncontrollable diarrhea so that she was continually soiling herself. Because of this she had to give up work, became increasingly depressed, and hoped for death. When her emotional and practical problems were straightened out, she was again able to reestablish control over the colostomy and resumed her previous activities.

Psychology of the Cancer Patient

In general, the psychology of the cancer patient is the psychology of a person under a special and severe form of stress. Cancer is usually perceived as lethal and as a particularly gruesome form of death. It is almost always intertwined with the necessity for major surgery. Stress of this sort activates childhood and infantile irrational fears as well as

realistic fears. There is a chance of recurrence of cancer. There is a chance of serious postoperative complications and operative death. The fear of some form of mutilation in surgery is very real, and the patient may feel overwhelmed by his anticipation of how seriously handicapped he may be.

The problems inherent in infancy and childhood are all more or less solved by patterns of adaptation related to the specific difficulties experienced. The diagnosis of cancer, the surgical experience, and the residual mutilation or deformity which follows surgery can either threaten or disrupt these adaptational patterns and activate the conflicts which they were designed to resolve. Consequently, many fundamental underlying emotionally charged convictions are brought close to the surface. The notion that mutilation is a form of punishment for sin, or fears of abandonment are common themes. For example, a woman whose mother had interdicted marriage and motherhood for her was subjected to a pelvic exenteration for carcinoma of the cervix uteri. She felt, and stated, that her mother had finally caught up with her and punished her for having married and having a child. Another woman with carcinoma of the breast stated that she had loved her body too much and was being punished.

Indeed, the impact of the experience and the changes produced by surgery may be felt by the patient indirectly and only as a reflection of the change produced in the attitude of some significant family member such as the spouse. The marital partner may be wholly unable to accept the changes in form and function, and consequently reject the patient. Instances have been known in which wives have refused any sexual contact whatever after the husband's operation.

Whenever stress of this sort occurs, it calls forth defensive measures. Such responses are quite characteristic for the individual and are more or less specific for the type of stress. The mechanisms of avoidance and denial are frequently invoked, especially preoperatively. Avoidance is a fairly common mechanism, based on the premise that if one makes something explicit it becomes true, and as long as something is kept out of mind, there is no need to worry

about it. Denial is a more forceful rejection of the entire threat; some women have refused to recognize that they have lost a breast or a rectum for a considerable time after the operation. A woman with an extensive pelvic cancer, which was later cured by pelvic exenteration, denied the implication of entrance to three nursing homes for terminal cancer and signed out of all of them on one pretext or another, in order to maintain the denial.

The patient may believe himself overwhelmed by the threat to his safety or to his ability to function and may become seriously depressed. He may show signs of being disorganized; he may be unable to decide on reasonable courses of action. This state of mind is usually accompanied by profound feelings of dejection, a sense of helplessness, a retreat from function, and at times by suicidal thoughts. When a patient is in this anxiety-ridden state, he turns desperately to other people for help and loses his "independence." He seeks advice, consolation, and reassurance from others. He seeks their help in making decisions and in solving problems. It should be emphasized that in the majority of patients depression and concomitant dependence are to be expected, but are only temporary. They can be regarded as a prelude to the process of repair. How temporary they are is dependent upon the amount of help the patient obtains in solving his real life problems, in the reintegration of his primary adaptive mechanisms, and in the restitution of function in the various significant areas of living.

Depression and dependence form the essential core of what is generally referred to as "regression." The patient should not be penalized because of these conditions. Rather, the problems which gave rise to them should be met. The patient may not be able to solve them alone unless he has adequate help, and chronic long-standing depressions, restriction of function, and pathological dependence may persist. Only too often he does not receive adequate help from professional sources and is left wholly on his own or receives from friends and family well-meant but inappropriate advice. Kindness, acceptance, and support, especially from professional persons, have been proved over and over again to be of great significance to the patient. They give him the security

that he needs to face the problems of later resumption of function. It should again be emphasized that marked dependence does not persist for long periods of time except in rare instances. The problems of long-term dependence are, as a rule, few. The majority of patients are content merely to know that there is someone on whom they can rely and with whom they can discuss their problems, even though they do not avail themselves of this privilege for months on end, if at all.

A patient at times attempts to master his difficulties by direct frontal attack, by sheer force of will. This is in effect a form of denial of limitations on his own power. When this process is not guided, it may result in inappropriate solutions which can be bizarre or inefficient, or it can result in failure, with accompanying intense feelings of defeat. As a matter of fact, overly enthusiastic attempts at mastery are closely akin to elation and are often a thin veneer for a very profound depression.

The belief that one has sustained a serious injury, often held by patients who have had extensive surgery, is usually associated with considerable resentment which, unfortunately, has no logical object. The physician is often seen unconsciously, or at the margin of awareness, as the injuring agent, but he is also regarded as too powerful or too necessary to offend. Consequently, resentment is often misdirected toward persons in the immediate environment—on nurses and social workers or on members of the family. Resentment is usually manifested by querulousness, a demanding attitude, complaints, and other manifestations of hostility. It often includes feelings of being the victim of others' hostility and, indeed, may be frankly paranoid. Irritating as this state is to those who handle the patient, it should be regarded as a part of the normal process of repair, although at times a miscarried process. When the anger and resentment can be vented and worked through, they do not persist as a permanent adaptive pattern.

The social worker is in a peculiarly advantageous position to aid the patient in his struggles to resume function. She can determine the real limitations imposed by the circumstances of the surgery and other therapy. She can mobilize community resources for the benefit

of the patient or his family. Her training in case work has taught her the proper approach to the emotionally disturbed patient. She can accept the patient's dependence and help him voice the resentments and fears on which his dependence is based. She can interpret his needs to his family and other important persons in his environment. She can strengthen or repair significant interpersonal and family relationships. Moreover, she can interpret to the physician and the surgeon the needs, both material and emotional, that the patient may have. Her professional status makes her an authoritative source of reassurance. Her training in meeting people's needs and helping them to solve practical problems makes her a very valuable ally for the patient in his struggle to resume his previous life.

Adaptation of the Patient

The surgical experience itself is probably crucial to the long-range adaptation of the patient. In the first place, a fairly large percentage of patients regard any major surgery as having a high probability of being fatal, or at least mutilating. Frequently, the extensive removal of body parts, especially of organs significant to the patient, is believed to be incompatible with health or vitality. When this conviction exists, surgery is approached with a keen expectation of serious injury, signaled by anxiety, confusion, and sometimes despair. It is when the expectation of injury becomes changed postoperatively into a belief that serious injury has taken place that problems of hypochondriasis and depression are most severe. The individual believes himself too enfeebled or frail to resume his premorbid functioning; consequently there is restriction of function, frequently in all areas of living. Unless these feelings are dealt with adequately when they manifest themselves, depression and invalidism may be permanent. As one patient said, "I have lost confidence in my body."

As yet no means are available to predict which patients will do well psychologically and which ones will not. No reasonable prediction can be made preoperatively that the patient fits into some particular diagnostic classification. As a matter of fact, neurotic or

psychotic mechanisms may be an asset in the total situation. When they are not disrupted, such mechanisms may shield the patient from the impact of the experience or enable him to resume function with little difficulty. A schizophrenic boy who underwent an amputation of the arm and shoulder for a bone tumor had little trouble in accepting this disability because it remained peripheral to his central problems of his own sexuality and his mother. No prediction can be made on the basis of gross adaptation, such as the fact that the patient seems to be a "well-balanced individual and a solid citizen." The physician must know exactly how this experience will integrate with or disrupt the patient's major patterns of adaptation. This is usually far too subtle to be determined before the event. Moreover, the final adaptation cannot easily be predicted on the amount of preoperative anxiety alone.

It has not been possible to develop instruments or tests to differentiate sharply between those who need help and those who do not. All patients who undergo major surgery with serious change in form and function such as that used routinely to manage and control cancer need help at some time in their course, particularly around the time of surgery.

Summary

The problems to be met in managing the cancer patient today are quite different from those of a few years ago. Operations which were considered impossible a short time ago are now routine, and postoperative care has been much improved.

All types of people have cancer. Each patient must be considered in the light of his individual problems; each one must make his own adjustment to the circumstances of his particular kind of cancer and its treatment.

No prediction can be made preoperatively of how the patient will react to surgical experience. No instruments or tests have been developed to differentiate sharply between those who will need help and those who will not.

The psychology of the cancer patient is the psychology of a person under a special and severe form of stress in which many fundamental underlying emotionally charged convictions are brought to the surface. Stresses are often met postoperatively by avoidance or denial, or depression and dependence may develop which the patient may not be able to overcome without help. Such problems can best be met by professional persons. The social worker is in a very advantageous position to aid the patient in his effort to resume normal functioning following surgery.

Psychosocial Aspects of Cancer

Two papers in this series, in addition to those appearing in this issue, were published in the October 1952 issue of *Public Health Reports*:

Professional attitudes and terminal care, by Charles S. Cameron, pp. 955-959.

Typical patient and family attitudes, by Addie Thomas, pp. 960-962.

A fifth article will be published at an early date.

The Sequence of Emotional Reactions in Radical Mastectomy Patients

By MORTON BARD, M.A.

At the Memorial Hospital in New York, we are in a position to observe the emotional reactions of large numbers of mastectomized women since an average of 580 radical mastectomies are performed each year. Our clinical observations have led to a number of formulations.

In the United States, the female breast is the most common site of cancer. It has been estimated that 4 percent of the adult female population develops the disease. Radical mastectomy is a universally accepted treatment of breast cancer and involves the removal of the breast, pectoralis major and minor muscles, and the axillary contents.

Public knowledge of the symptoms and treatment of breast cancer is more widespread than for other forms of cancer. The symptoms of breast cancer cannot be easily attributed to other illnesses as can the symptoms of rectal or gastric cancer. Most women in our society are aware that a painless mass in the breast is a pathological sign. Furthermore, they have known either relatives or friends who have had a radical mastectomy. Unfortunately, women who have had a mastectomy and are free of recurrent disease rarely allow others to know about it. Those who die from recurrent disease,

despite surgery, are the patients more generally known in the community. As a result, many women regard the prognosis for breast cancer as unfavorable even if treated.

When a woman discovers a mass in her breast, she is likely to recall every unfortunate incident involving breast pathology known to her. As soon as she is aware of the symptom, a sequence of emotional reactions and reality events begins. The sequence can be characterized as consisting of four stages: onset of symptoms, diagnosis, hospitalization for surgery, and convalescence. Each phase contributes to the patient's ability to integrate the total experience, and, modified by her lifelong adaptations in living, sets the tone of her postoperative reactions.

Onset of Symptoms and Diagnosis

When the symptom of breast cancer is recognized, the patient immediately begins to anticipate what she believes is going to happen to her during the treatment process. The individual meaning of the suspected disease and surgical treatment serves to mobilize the patient's anticipatory anxieties and preparatory resources. Often, the symptom arouses such acute anxiety that the patient delays seeking medical attention. Or, if medical help is sought, a series of defensive maneuvers may be initiated to avoid the inevitable treatment process. Fortunately, many women are able to seek medical attention and carry through the necessary treatment.

This does not mean that these women obtain

Mr. Bard is assistant research clinical psychologist, Memorial Hospital, New York, N. Y. This paper was presented on the American Cancer Society's program at the National Conference of Social Work, Chicago, May 27, 1952 (see Public Health Reports, October, p. 955).

medical treatment without great emotional cost to themselves. Because of the amount of information which most women have about breast symptoms, the most frequent concern of the patient is whether or not she has cancer. To most, this concern can be equated with, "Do I have that invariably fatal disease?" However, other important fears may also be activated when the symptom is first discovered. Concern about recurrence if the diagnosis should prove to be cancer is often experienced even before treatment is initiated, or concern about mutilation if surgery should prove necessary is expressed. Some women are particularly worried about the effect of the entire experience on their families—"What will happen to my children when I'm in the hospital or if I die"; others cannot specify their fears—"I'm just scared and I don't know why." With the onset of symptoms, then, the patient immediately begins to anticipate the disease and its treatment.

On the day that the diagnosis is established and the patient is informed of the necessity for surgery, all of her anticipatory fears are brought clearly into focus and invested with reality. Whether or not the patient is told she has cancer will depend on the interaction between the physician's convictions about imparting information to cancer patients, and the patient's insistence to be told details. In either case, however, the patient's dread begins to mount slowly and progressively.

Hospitalization

The day of admission to the hospital has tremendous significance. On this day patients are frequently in a state of panic. The awesome, impersonal routine of preparation for surgery is in itself frightening. Patients interviewed on this day express feelings of being trapped and helpless. Some patients actually telephone their families and request that they be taken home as a last desperate effort to thwart the threatening environment. If they are clinic patients and are placed in a breast ward, they will selectively perceive the operative experience of others. The patient's experiences on the day of admission to the hospital reinforce the fears which arise at the onset of symptoms.

Immediately before surgery, specific fears concerning anesthesia are expressed. A majority of patients insist that total anesthesia must be induced before they can possibly undergo surgery. Some patients ask that they be "completely out" even before going to the operating room. Other patients express fear of losing consciousness as a result of anesthesia. All of the feelings regarding anesthesia are indications of integrative attempts to deal with an overwhelmingly threatening life situation and, again, are very individual.

Other reflections of tension or panic occur prior to operation. Eating patterns are usually disturbed, and restful sleep the night before surgery is an impossibility for most patients, sometimes even with sedation. Dreams occurring on the night before surgery are usually nightmares of intense horror. For example, one patient reported that in her dreams she found herself in a butcher shop with female breasts suspended from meat hooks all around her, although her own breasts were intact. This dream and others of an equally horrible nature emphasize the anticipatory fears of surgery.

Postoperative reactions also attest to the nature of the experience. Once again, horror dreams are frequently reported. Gross physiological reactions, such as excessive perspiration and tachycardia, are manifested. Most patients have difficulty in eating after surgery; they are unable to swallow food, or they have lost their appetites. Again, there are a variety of sleep disturbances: inability to fall asleep, early waking, fitful and restless sleep, and arising fatigued. During the day, some patients sit quietly, sometimes crying, without participating in any ward activity; others are overactive, often eagerly helping nurses with their work.

The gross physiological reactions, disruption of eating and sleep patterns, the dreams, and ward activity all comprise a response to a hostile and injuring environment. These reactions, with marked individual variation, are actually a watchful mobilization of inner resources to prevent further injury. One author has succinctly said that, "the operation" is a milestone—if not a tombstone—in the life of an individual."

myself." Self-pity is usually accompanied by feelings of misgiving and guilt and at this time the psychiatrically trained worker can help the patient by assuring her that there is nothing wrong with feeling sorry for oneself. Successful resolution of these feelings results in resumption of functioning and interest in the environment.

We must be entirely realistic in appreciating the terrifying nature of surgical experiences, particularly when an organ of great psychic

significance is involved. Radical mastectomy patients need warm support and understanding if they are to meet the threat of the situation. If this support can be routinely forthcoming to all patients, many women will be spared intense emotional reactions and limitations in living. The radical mastectomy patient can live a full life after cancer surgery but only if we accept our obligation to aid in the process of reducing trauma and restoring function.

Employment of the Physically Handicapped

The Federal-State employment services report the placement of 2,400,000 physically handicapped workers in nonagricultural employment from January 1, 1940, to July 1, 1952. Additional hundreds of thousands of workers with disabilities found employment through other sources.

These cumulative figures, cited by the President's Committee on Employment of the Physically Handicapped in connection with the eighth observance of National Employ the Physically Handicapped Week, which took place October 5 through 11, are indicative of the progress that has been made in placing persons with disabilities into productive employment. The task, however, is a continuing one. It is estimated that another 2 million men and women can be added to the labor force if rehabilitation services are made available to them, according to a report made by a special Task Force on the Handicapped to the Office of Defense Mobilization.

The Veterans Employment Service reports that, in spite of favorable labor market conditions and a record of 124,000 disabled veterans placed in 1951, 40,500 disabled veterans were looking for work in April 1952. An additional 50,000 disabled veterans are taking training or schooling under vocational programs sponsored by the Veterans Administration and will be looking for jobs in the near future.

Additional figures indicative of the success of the efforts in behalf of the physically handicapped and of the work yet to be done come from the Office of Vocational Rehabilitation. During fiscal 1951, the local offices of State divisions of vocational rehabilitation rehabilitated into employment nearly 67,000 men and women. Another 150,000 are receiving services which eventually will enable them to work, about 75,000 of whom will be ready within the next year.

These 67,000 men and women who overcame helplessness in 1951 added more than 100 million man-hours to the Nation's productive effort, according to the Office of Vocational Rehabilitation. They increased their earnings from \$16 million to \$116 million a year.

A breakdown of these 1951 figures indicates that 5,696 of the physically handicapped who found employment had hearing disabilities. About 1,500 were deaf and 4,200 were hard of hearing. These 5,696 people increased their earnings from \$2,300,000 a year to more than \$10,000,000 the first year, an increase of 341 percent.

Methodology of a Family Health Study

By CHARLOTTE F. MULLER, Ph.D., ANNE WAYBUR, A.B.,
and E. RICHARD WEINERMAN, M.D., M.P.H.

The family health study conducted in 1949 at the University of California represents an experimental effort to design a method of investigation useful in getting accurate and complete information on morbidity and medical care among families.

At the outset, the complexity of factors defining health status was recognized. The objective was set of designing techniques that would embrace the full array of health experiences and would permit the correlation of complicated data on family and personal characteristics, illness, disability, preventive and therapeutic services, and expenditures for medical care.

Previous studies of health experience in the population provide a background for all fresh attempts (1). Many of their techniques and findings were utilized in the development of the experimental method presented here. Past studies, however, often were based upon single interview samples, used complicated schedules, or were restricted to certain aspects of the family health complex.

A new method is sought—one that will minimize dependence upon remote memory, will establish continuous relations between survey sample and research team, and will provide a means of recording and correlating many kinds of interdependent health information.

This paper is a product of the School of Public Health, University of California, Berkeley. It was presented before the medical care section of the seventy-ninth annual meeting of the American Public Health Association, San Francisco, November 3, 1951.

Important changes in science and society, which have affected illness and health care, demand new approaches to research in health. Revolutionary clinical advances, new trends in the organization of medical and hospital service, new statistical techniques—all have appeared since the last comprehensive health surveys in the 1930's. Up-to-date information about illness—its incidence and prevalence, the medical needs it creates, the effect upon family economic status—is needed in order to formulate, revise, and administer health programs.

In the family health study, the opportunity existed to test some new techniques and to collect comprehensive data on health experience among a special sample of urban families. This report describes the study population and, in some detail, the methods under trial. It does not present the statistical findings, which will provide a more definitive basis for evaluation of the survey techniques.

The Population Sample

The study grew out of a health survey conducted in October 1948 by graduate students at the University of California School of Public Health, among employees of the university at Berkeley. In order to compare different techniques, the 4,800 employees were divided into several random samples. One sample, consisting of 815 employees, was surveyed by personal interview and each person was asked whether he would be willing to keep a daily health record for his family in a later study.

Losses from the study sample can be divided into two groups: those occurring before the actual beginning of the study and those occurring

during the study. Table 1 summarizes all changes.

Of the original 815 employees, 160 were not available for the initial interview; 592 (or 90 percent of those actually interviewed) agreed to participate; 63 refused. The problem of sample losses due to employment turnover was a major factor from the very beginning. Sixty-four employees left the university before the initial interview was held in October 1948, and 28 left between the initial interview and the start of the study in April 1949.

Thus, 564 employees and 797 members of their families constituted the starting study population of 1,361 individuals. Over the 5 months of the project 60 employees and 72 family members were lost and 37 family members were gained, giving a final total of 1,266. Fifty-seven of these 60 employees and their 60 dependents were lost through termination of employment: 3 went on leave of absence; death claimed one family member; and changes in family composition accounted for 11. No one who actually started the study refused to complete it, although a few did not cooperate fully.

Characteristics of the study population were compared with available data for the United States, the West, the urban United States and West, and the San Francisco-Oakland metropolitan area.

In general, the study population may be characterized as a relatively young, married, employed, white-collar, urban group with more

females, younger children, and larger incomes than the general population. Its social characteristics were potentially favorable to good health and adequate medical care, but the high proportion of women in the child-bearing ages and young children could be expected to increase medical needs.

Methods and Materials

The main features of the experimental method were a specially designed family health record booklet, regular monthly interviews by a trained interviewer, and an integrated inquiry into morbidity, receipt of health services, and health expenditures. The booklet was designed to be used at home by the family for daily recording of health experiences, and the periodic interviews with the employee-respondent were held at work. The booklet, however, was kept at work by a number of employees to avoid forgetting to bring it from home on the day of the interview. This practice, of course, interfered with daily recording, but the complication was hard to avoid since the interviews were scheduled at work.

Family Health Record Booklet

The design of the family health record booklet presented some difficult problems. The record had to include all aspects of family illness and medical care. It had to be simple, orderly, and free from a confusing array of complicated items. It had to encourage complete recording and precision as to dates and dollar values. While language was kept as simple as possible, simplicity often conflicted with precision and adaptability. To some extent, verbal explanations were necessary to mediate between these objectives.

The booklet, entitled "Health Record—Day by Day," was attractively printed. A calendar was provided on the inside front cover for convenience in recording dates of health events. Different page colors were used to identify the various sections of the booklet. The first page presented simple instructions and definitions. A plastic loose-leaf binding permitted withdrawal, insertion, and rearrangement of pages in the event of family changes. The booklet was offered as a permanent possession to the

family, the statistical data being transcribed monthly by the interviewer.

Section I, "Family List," was devoted to an initial recording of demographic and social data on each family member—age, sex, relation to head of family, marital status, employment, and health insurance coverage. It was decided not to request income data until the final interview. At that time a separate schedule was completed, which included information as to the existence of a "personal" or "family" physician as related to the family's length of residence in the community.

Section II, "General Health Problems," was devoted to the recording of all underlying illnesses and impairments. Careful memory prodding by the interviewers helped to bring to light the host of chronic complaints, dental and visual defects, partial incapacities, and general health deficiencies so often omitted from health inventories.

Section III, "Health Insurance Coverage," took up an entire page. Although the complexity of public and voluntary medical care plans presented a difficult recording task, efforts were made to obtain data on the name of the plan, duration of coverage, premium costs, and type of benefit for each family member.

Section IV, "Record of Immunizations," comprised the fourth page. Data on past immunizations were collected only for children under 10 years of age. (Current immunizations were recorded for all family members on the monthly record sheet.) A special effort was made to find out where and by whom the immunization was performed, in order to ascertain relative roles of the health department and the practicing physician.

These four sections were filled in during the first visit, with the help of the interviewer. The subsequent sections were designed for daily recording of current health events and were reviewed monthly by the interviewer.

Section V, "Daily Record of Illnesses, Injuries or Disabilities, and of Services Received," was in many ways the heart of the record. Each family member had a separate page for each survey month. Under the proper date, check marks in appropriate boxes indicated days ill, days disabled, and days on which different kinds of home, office, clinic, or hos-

pital care were received. Space was provided for diagnosis or nature of symptoms for each episode. Every effort was made to relate morbidity to service received. Preventive, diagnostic, and therapeutic procedures were identified under the heading "Reasons for Visits."

Much discussion preceded the design of the recording method for duration of illness and of disability. The problem of illness without definite disability was handled by checking separately days of symptomatology and days of at least partial interference with usual activity. In this way, both the subjective designation of illness and the objective experience of disability could be recorded. (See also p. 1154 for discussion of illness and disability.)

Section VI was a "Monthly Record of Expenses for Health Services." One page was used for all family expenditures for health goods and services, since one source of payment for all family members is common and bills for the family are often not itemized. This record included professional fees, hospital charges, money spent for drugs and supplies, laboratory and X-ray costs, and health plan premiums. There were three columns: bills received, individual cash payments, and total cash payments in the month.

Section VII, "Monthly Expenses for Persons Not on Family List," was designed to obtain data on health expenses incurred for institutionalized relatives and others not in the household.

Monthly Interviews

The monthly interviews, which provided a regular contact between the research staff and the study population, were conducted by two female interviewers especially trained for this project. They both participated in preparing material for the study and organizing the data for statistical analysis.

The interviews were designed to serve many functions. Through them the respondent was to be thoroughly informed and instructed concerning the conduct of the study. Close rapport was to be established with him through repeated visits by the same person. Recordings for the previous month were to be reviewed and corrected; questions were to be asked to elicit

further recall and encourage maximum use of the daily record sheets. The chief operational purpose of the interview was to transfer the booklet data onto transcription forms for later analysis.

The interviewer avoided the questionnaire approach, presenting herself instead as a "consultant" who was available for assistance. Because of the variety of data requested, many cross checks on completeness and accuracy were possible. Discussion led by the interviewer was a vital adjunct to the booklet.

At the first monthly interview, general demographic and health information was collected, terms used and the method of record-keeping were reexplained, and health events already recorded were transcribed. At the final (sixth) interview, the entire booklet was checked against the transcribed record, inconsistencies and omissions were remedied where possible, and, in particular, chronic health problems and expenses were reviewed for completeness.

Preliminary Activities

A preliminary dittoed draft of the booklet was pretested and modified before the booklet was printed. The study was initiated by sending an introductory letter to each person who had agreed to participate. The letter described the booklet, reviewed the objectives of the study, and explained the role of the interviewer.

A visit was then made to each employee participant, during which a sample booklet was shown and the recording method explained in detail. This initial visit also served to confirm and extend participation by a maximum

number of the original sample. The best time and place for subsequent interviews was determined. A supplemental instruction sheet was felt to be desirable and was prepared to accompany the printed booklet. Through these visits, the final composition of the sample was ascertained. When the printed booklets were received, they were numbered, adapted to family size, and mailed out.

Quantitative Evaluation of Methodology

Losses from the original employee sample were sizable, numbering 311 out of 815. Of these, 251 left before the study actually began. As previously indicated, sample losses were due primarily to changes in employment status and normal changes in family composition. Relatively few of the original random sample expressed unwillingness to participate, and none dropped out for this reason during the survey. Nevertheless, the employees who did not complete the study, plus their family members, constituted a significant sample loss.

The possibility must be considered, therefore, of bias in the health record resulting from sample losses, even though the original sample is not representative of the general population and the specific statistical findings have only local application.

An exact measure of the effect of these losses must await analysis of the ultimate findings. Meanwhile, the possible bias was estimated in two ways: (a) by comparing employees who completed the study with those who did not, in terms of their morbidity rates as shown in

the previous student survey, and (b) by tracing changes in the age, sex, and marital status distribution of employees remaining over the course of the study to see if the character of the original sample was altered. Unfortunately, data on family dependents were not available in the earlier student survey; therefore, full sample comparisons were not possible.

In the first analysis, three indexes of previous health status were compared: (a) acute disabling illness during the month of the student survey, (b) chronic conditions not disabling in that month, and (c) so-called "health gripes" (conditions causing "irritation or discomfort"). All findings were expressed as percentages of the group in question reporting such conditions. Of these indexes, it was only the first—disabling illness—for which a significant difference was found between employees who completed and those who did not complete the family health study. Nineteen percent of the "completed" group reported disabling illness during the month, as contrasted with 26 percent of those who dropped out. This difference could have arisen by chance less than twice in 100 trials, if both groups came from a population homogeneous as to risk of illness.

Sample losses might thus have resulted in an apparent reduction in the risk of acute disabling illness where no such reduction had actually occurred.

In the second analysis, study of changes in key characteristics of the employee group revealed significant change only as to age, when beginning and end dates were compared. The percentage of employees under 25 years of age dropped from 14.5 percent to 9.1 percent dur-

ing the course of the project. It is inferred from findings of the National Health Survey on the relation between age and disability (2) that such a shift could increase the risk of acute illness, thus tending somewhat to offset the influence of the finding in the first analysis.

The reason for leaving the study was not significantly related to health status at the time of the prior survey. No significant differences were found among those who left the study for various "objective" or "subjective" reasons, or at different times.

Test of Completeness of Information

A test was performed to see if the repeated interviews used in the study were an especially useful method of securing completeness of data on the existence of long-standing chronic disorders. Findings on pre-existing cardiovascular-renal disease as reported at successive interviews were analyzed. Of the 87 conditions in this diagnostic group, 86 percent were reported at the first interview and 14 percent at one of the five later interviews. Among the 14 percent not mentioned at the first interview were some serious and potentially expensive cases (e. g., rheumatic heart disease). The rapport built up through continuous relations with respondents and the recall value of probe questions by interviewers are felt to have aided in stimulating more complete disclosure of chronic conditions as the study progressed.

Adequacy of Record-Keeping

Completeness of recording in the special health booklet was evaluated to ascertain (a) whether the recording form, as distinguished

from the repeated interviews, contributed substantially to collection of data, and (b) what circumstances influenced the degree to which the booklet was used.

Completeness could, of course, be checked only against data provided to the interviewer in the booklet or verbally, not against events never disclosed. Each booklet was roughly graded at each visit as having complete, partial, or no recording for the preceding month. If the respondent saved assorted jottings and bills for the interviewer, a "partial" grade was given.

Of 500 employees graded, a monthly average of 81.0 percent had some data to report. Of those reporting data, 41.7 percent entered all of the information in the booklet, 29.6 percent recorded incompletely, and 27.0 percent made no entries at all (table 2). Language difficulties, fear of spoiling the book, and, in some cases, indifference were found as reasons for not recording data, but many of the nonrecorders referred to the order of items in the booklet in making verbal reports.

Factors considered as possible influences on the adequacy of record-keeping were statistically analyzed. The results were as follows:

1. There was no clear-cut relationship between adequacy of recording and willingness to keep the health record when originally approached. Differences in adequacy among those who originally agreed, refused (some who refused the student interviewer were willing to participate when revisited by a survey staff member), or were not contacted until the spring of 1949 were not statistically significant. They could have occurred by chance alone in more than 70 out of 100 trials. Apparently once the employee decided to participate, his original attitude did not decisively influence the adequacy of his recording.

2. Record-keeping declined slightly during the course of the study (table 3). The changes are statistically significant, since they could have arisen by chance alone in less than 5 out of 100 trials. They reflect, at least in part, the difficult period of summer vacations. An upward swing was discernible in the month of September when vacations were over and when final, and especially comprehensive interviews were given.

3. Professional, clerical, and skilled workers

recorded more adequately than service and unskilled workers. Variations in adequacy among occupational groups, shown in table 4, could have occurred by chance alone in less than 2 out of 100 trials.

The main problems were the sustaining of active participation over time and the securing of adequate written records from different occupational groups.

Qualitative Appraisal of the Method

The following qualitative appraisal of the methods used in the family health study is presented as a supplement to the statistical evaluation. It is based upon the personal experience of the interviewers.

Family Health Record Booklet

In general, the family health record booklet served its primary purposes well. The significant advantages of the booklet appeared to be the following:

1. Its comprehensive array of designated health items stimulated a fairly complete reporting of family health experiences, even when separate jottings rather than the booklet pages were used.
2. Its daily check-mark system favored the regular recording of current events and aided memory.
3. The attractive design and the offer of the booklet as a permanent family possession encouraged respondents to use it. Other practical uses for the booklet, such as a record for tax purposes, for family budgeting, and for medical reports to the physician, were also discovered.
4. Its scope of information made possible a meaningful approach to family health, since social factors, previous health status, morbidity rates, medical services received, and expenses incurred could all be correlated.

Among the definitions of terms used in the study, those for "illness" and "disability" were the most difficult to apply uniformly. The statement in the booklet limited "illness" to conditions at least partially disabling, that is, producing "pain or discomfort severe enough to interfere, at least in part, with the performance of usual activities, at home, at work, or at school." But the frequent receipt of medical

care for nondisabling conditions and the pursuit of "usual" activities (at least, work) while clinically ill were grounds for broadening the concept. In the final interpretation, explained verbally to the respondents, all nondisabling current health disturbances, all days spent as a hospital patient and at home following discharge, and illnesses disabling during part of their course were included as illness. By checking "yes" or "no" to the question, "Performed usual activities?" days of disabling illness were recorded separately from days of nondisabling illness. Thus disabling, nondisabling, and total morbidity could be tabulated. Individual interpretations, especially regarding preschool children and convalescent periods, remained, of course, to impair uniformity of findings.

The definition of "family" was also important, because it influenced the selection of persons included in the study. A unit based on related persons dwelling together was adopted. This was modified in a number of cases where related adults (other than couples) in the same household maintained independent ways of life.

The Interview Method

Successive visits by the same person were useful in building up rapport with respondents and in filling in gaps in information. But some employees did not welcome interviews, feeling that they could keep the record adequately without aid and that they could not spare the time.

Interviewing on the campus was economical

of personnel time, both in travel and in the interview itself. Most employees were reasonably certain to be at their jobs at the scheduled time. It is possible that some who permitted this type of interview would have opposed household visits. But in many situations, a home visit might have contributed to more relaxation, privacy, and full attention. A few home visits were made when circumstances required.

Contact with family members, particularly the housewife, would have secured more complete information; at least in some cases. This was not feasible within the limits of this study.

Dramatic occurrences, such as injuries and hospital experiences, were more clearly recalled than minor episodes of illness, routine health services, and details such as exact duration of an illness. In other instances, the obstacle to collection of complete data was unwillingness to disclose family situations, primarily marriage and pregnancy. A few such cases came to light when the critical period in personal life was over and the respondent volunteered information. There may have been other cases where the data were lost.

Summary and Conclusions

1. The family health study of the University of California was designed to assay a method of collecting information on the full complex of health experience, with less dependence on memory than in interview studies and with

plans, a system of prepayment for hospital care. We can be proud of the enrollment of 42 million people in these programs.

Although voluntary prepayment solves the problem of financing hospital care for many individuals, there are still large numbers of people who cannot now be covered by prepayment plans and who are unable to meet the cost of high-quality care. These people are the indigent and those who experience catastrophic illness. Financing the cost of hospital care in the event of poliomyelitis, tuberculosis, or mental disorder, to mention but a few illnesses, is a catastrophe to any family, even when covered by most prepayment plans.

As a supplement to their income from patient service, hospitals receive substantial financial support through charitable contributions. In many instances, these contributions have meant the difference between high- and low-quality care. In others, they have been the deciding factor between some care and no care. Gifts of philanthropists have made possible special studies in hospital administration and organization, and research into this phase of hospital care has been financed largely from this source. So far, however, such financing has barely begun the broad studies which should be undertaken.

While the average voluntary hospital is blessed with community support, it rarely has sufficient financial resources to undertake significant research that might affect nation-wide hospital operation. Research is usually applied only to a local situation. The individual hospital is seldom able to disseminate its findings to the general hospital field so that patients of other hospitals will benefit. The scope of study and research is perforce limited almost always by financial considerations.

The solutions of the economic problems of patients and hospitals have moved beyond the resources and responsibilities of the individual hospital. Now needed are coordinated action and a rededication to the common purpose by all hospitals. Some means must be found whereby all hospitals can benefit from the hospital studies undertaken throughout the entire country.

The ultimate success of inquiries into more effective and more economically produced care

must be based upon a search for new methods of administration by all hospitals. Progress will depend on an orderly study procedure and wide dissemination of findings. It will require cooperation.

Problems of Management

What are the more perplexing management problems? It has been frequently said that hospital administration requires all the skills of industrial management in addition to the special facility to deal with professional groups, the understanding necessary to maintain good relations with a special clientele, and the organizational ability to keep the hospital functioning 24 hours a day, 365 days each year. Ours is a tremendous assignment. It is one which tests the best in all of us.

The complexity of hospital management sometimes opens it to criticism and censure—frequently by people who are not completely informed. Yet, hospital administrators, as guardians of the public health, by accepting their assignments, have implied a willingness to assume responsibility for the best possible performance. Improvement of hospital administration is a part of that responsibility.

Hospitals have, on occasion, been suspected of lagging behind industry in the acceptance and use of modern business practices. Some management engineers believe that only 10 percent of business is efficiently administered. If this is true, it cannot be denied that some hospitals, too, are not operated at peak efficiency.

The average hospital has as many as 20 special departments encompassing no less than 185 different jobs. The average industry entails only 65 or 70 different jobs. This comparison points up the complexity of the administrative tasks in hospitals. Determination of ways to coordinate hospital specialists into an efficient unit to work with medical scientists in serving the best interests of patients is another task.

However, it should be remembered that the administration of a hospital differs greatly from that of general industry and requires different methods of operation. Many of these methods have not been critically explored. Little is known about the most effective way of solving many of the complex problems of hospi-

tal operation. A broad inquiry into administrative procedures is overdue in the hospital field.

The hospital product is service, and it is provided through the efforts of people. The high quality of health care required by the public demands competency and a full supply of trained persons. Unfortunately, these persons are not available today, either in the quality or quantity needed. Recent studies of special departmental functions pointed up large deficiencies between supply and demand of personnel. Such shortages create special management problems which need solution.

The Administrator

The hospital administrator must develop a thorough understanding of the hospital field by familiarizing himself with national and local programs. He must have knowledge of specific skills in all the technical phases of hospital activity. He must organize in-service training courses for hospital technicians. He must integrate the special skills of hospital personnel into a working organization. The administrator must have the broad knowledge of human relations which comes from assurance in job knowledge, from training in administration, and from ability to inspire and motivate people to work together.

Coupled with these specific responsibilities of administration is the broad responsibility of the hospital governing boards for policy and standards. Questions and decisions of policy which relate to legal and financial matters and quality of care pose problems which are peculiar to hospitals. The administrator must bring to members of the board all the information they need so that both they and he may provide an effective community service. Many problems of board authority and relationship as yet are unsolved. Greater efforts must be organized to help hospital board members understand and resolve the numerous issues for which they carry major responsibility.

Interdependence With Medicine

During the past 25 years, impressive advances have been made in the field of medical sciences. With this progress has come an increasing in-

terdependence of physicians and hospitals. And as research has been conducted, as inquiries have been extended, as investigations have been advanced, this interdependence has increased proportionally. The end result has been the creation of a relationship inextricably binding hospitals and medicine together.

The interdependence of the physician and the hospital has created many problems. The hospital is straining to cope with the myriad complexities arising from the application of the advances in medicine. In many hospitals, particularly those in rural communities, the introduction of the most advanced medical techniques developed during this supersonic age is performed under what are virtually horse and buggy managerial circumstances. The results, although seldom disastrous, can be said to handicap the efficiency of the team working to produce high-quality health care.

The rapid development of new medical methods in recent years has taxed the ingenuity of hospital administration. The hospital must meet scientific advances through changes in its physical plant, in equipment, and in procedures, and through the development of new personnel skills. Some delay in making these changes is inevitable. The time lag cannot be lengthened—it must be shortened.

To focus on serving the health needs of the community and to act in partnership with the physician, hospitals need men of leadership and training in the most progressive managerial skills. Hospitals must keep pace administratively with the technical progress of the medical sciences.

Also, hospitals need national coordination through an experimental and investigative service to develop techniques and to disseminate information promptly to bring to all physicians, hospitals, and patients the full benefits of medical progress.

Challenge of Social Changes

Hospitals must plan to meet the needs of a growing population. They must initiate programs of care for increasing numbers of aged persons. They must expand their facilities to permit greater service as community health centers. They must inaugurate more effective preventive health care programs.

Population increase, the lengthened life span, concentration of life-saving services, and emphasis on prevention of illness are all phenomena of the virile society in which we live. All introduce problems. All will complicate administration. None can be ignored.

Today we observe this expanding horizon of hospital responsibilities. Today we must plan to meet them so that by tomorrow they can be added to programs of public service. More study, more research, more experimentation, and extended education will be required to accomplish our objectives with dispatch and success.

Future Progress

It is apparent that hospitals all over the country reflect the achievements which are possible when members of a community band together. Voluntary hospitals which are primarily managed by governing boards whose members have volunteered services in interest of the public illustrate one notable accomplishment of free enterprise.

The extension of services and the increased use of hospital facilities will add to economic problems of patients and hospitals alike, requiring special study and development of im-

provement and extension of prepayment plan for the purchase of care and more efficient methods of production and distribution of care.

Emphasis on management engineering will dictate the need for top administrative skill, for more highly trained personnel, and for improved operational patterns.

Continued advances in medical science will require greater knowledge of medical administration, strengthened relationships between hospitals and physicians, and emphasis on the development of new techniques for applying medical knowledge.

Social changes will open new vistas of hospital service.

As large and as overwhelming as is the job ahead, we can take courage and new faith as we review the progress of the past. The path to the goals of the future must be built upon a system of research and an orderly collection of information about the varied facets of hospital administration. Future objectives can only be obtained by a hospital-action program which applies new administrative procedures, cooperatively developed and disseminated through intensive research and education but focused on better care of the sick.

Atkins to India, Board to Sanitation Post

C. H. Atkins, chief of the Division of Sanitation, Public Health Service, since 1948, has been assigned as chief sanitary engineer of the Public Health Mission to India under the Point IV program, Technical Cooperation Administration. The new assignment also carries the duties of assistant chief of the mission, chief sanitary engineer of the Government of India, and visiting professor of sanitary engineering at the All-India Hygiene Institute.

Succeeding Mr. Atkins as chief of the Division of Sanitation is Leonard M. Board, assistant chief since 1948. Mr. Board, a commissioned officer in the Service since 1943, received his master of public health degree from the University of Michigan. He is a fellow of the American Public Health Association, a past chairman of the Conference of Municipal Public Health Engineers, and a member of the Conference of State Sanitary Engineers, and of the American Society of Civil Engineers.

Reporting of Fetal Deaths in New York City

By CARL L. ERHARDT, B.B.A.

FOR MANY YEARS New York City has tacitly required reporting of fetal deaths at all periods of gestation by omission in its sanitary code of any qualifications as to the gestation age to be reached before reporting is required. Prior to 1938, "still births" were required to be reported within 36 hours of the event whereas live births were reportable within 10 days, but no further definition or distinction was indicated.

In 1937 the late Thomas J. Duffield, then director of the bureau of records and statistics of the New York City Department of Health, realizing that many physicians were failing to comply with the intent of the law, recommended that the code be revised to express more specifically the requirements regarding reporting of fetal deaths. He recognized that data which could be obtained only by mass reporting of early fetal deaths were of value in investigations of early pregnancy wastage and that these data would also provide a more nearly complete base for calculation of a puerperal mortality rate. Accordingly, in 1938 the board of health, with the advice of the obstetric advisory council to the commissioner of health and with the approval of the county medical societies and the New York Academy of Medicine, adopted a complete new section, defining fetal death and specifying signs of life as follows:

Mr. Erhardt is director of the bureau of records and statistics of the New York City Department of Health. This paper is based on one presented by him before the working group on natality statistics at the Public Health Conference on Records and Statistics in Washington, D. C., March 25, 1952.

"The term 'fetal death' . . . shall mean a stillbirth or a fetus delivered at an abortion (spontaneous, therapeutic or induced), that is, a fetus born dead, including a fetus recovered at operation in a case of ectopic gestation, by cesarean section, and a hydatid or hydatidiform mole delivered spontaneously or by operation.

"The term 'born dead' shall apply to any fetus in which there was no sign of life, such as respiration, heart beat or movement of voluntary muscle, after complete separation (head, trunk and limbs) from the body of the mother, notwithstanding whether the cord was or was not cut or the placenta was or was not removed."

This is the first usage, within the writer's knowledge, of the term "fetal death" in legal reporting requirements. The revision antedates by 12 years the WHO recommendations that the term "stillbirth" be discarded in favor of the term "fetal death" in describing termination of pregnancy otherwise than in a live birth and that statutes require reporting of all fetal deaths regardless of gestation age (1).

The revision, together with a determined effort by the health department to familiarize physicians and hospitals with the intent of the law, produced immediate results. However, within a few years, it was seen that the physicians were still confused as to the intent of the law. The phraseology did not make obvious the expectation that all instances in which postabortal indications of pregnancy, even pathologically diagnosed, came to the physician's attention would be reported. In 1947, therefore, the sanitary code was revised to define a fetal death thus:

"The term 'fetal death' . . . shall mean any terminated pregnancy resulting otherwise than in a live birth and regardless of the period of

Table 1. Ratio of reported fetal deaths to 1,000 live births, by period of gestation, New York City, 1937-51

Year	Total	28 weeks and over	20-27 weeks	Under 20 weeks	13-19 weeks	Under 13 weeks	Unknown period

1950	105.3	14.9	8.6	78.6	15.7	62.9	3.1
1951	110.3	14.8	8.5	82.0	14.5	67.5	4.5

gestation, and shall include a stillbirth, a fetus and fetal tissues, recovered at a curettage, delivered at an abortion or miscarriage (spontaneous, therapeutic or induced), at operation in a case of ectopic gestation, or by cesarean section, and a hydatidiform mole delivered spontaneously or by operation. The term 'fetus' . . . shall mean and include any of the above."

Direct reference to reports based upon laboratory examination was included for the first time: ". . . when such report is based upon pathological examination of tissues recovered at an operation such report shall be filed within fifteen (15) days of the operation," rather than within 24 hours as otherwise required.

Effect of Legal Changes on Reporting

The data in table 1 and figure 1 provide ready evidence of the immediate effect of the revisions of the sanitary code. The fetal death ratio to 1,000 live births rose from 48.9 in 1938 to 66.8 in 1939, a 37-percent increase in 1 year. The 1951 ratio of 110.3 to 1,000 live births is more than double that of 1939. The number of reported fetal deaths rose from 4,995 in 1938 to 6,831 in 1939 and has continued a rising trend since that year, reaching nearly 18,000 in 1951. But of more interest than the changes in the total volume are the changes, or lack of them, in

groups of fetal deaths divided according to number of weeks of gestation.

The ratio of fetal deaths of 28 weeks' gestation and over to total live births has exhibited a consistent downward trend, reversed in only 1 year, 1944. By 1951 the ratio had declined by 44 percent from that of 1937, from 26.3 per 1,000 live births to 14.8.

No definite trend in the ratio of fetal deaths of 20 to 27 weeks' gestation to total live births is evident. Although the comparatively stationary ratio can be interpreted as lack of any change, it is also possible that a greater proportion of fetuses are carried forward toward term and that this number is compensated by an equal proportion carried beyond the nineteenth week into this interval.

Fetal deaths occurring before the twentieth week of gestation have increased from 48.7 percent of the total reported in 1939 to nearly 75 percent in 1951. It is from this group that the increase in both the number of reported fetal deaths and the ratio thereof to live births has resulted. It would, however, be a fallacy to conjecture any increase in early fetal deaths from these data; the rise is probably due entirely to increased reporting of the early deaths.

Unfortunately, data for finer subdivisions of this period of gestation are available only since 1947. Even in this brief period, however, considerable increase can be shown for fetal

deaths of 13 to 19 weeks' gestation and for those of less than 13 weeks. The ratio to live births for the latter group increased by 66 percent and for the former by 13 percent.

General Pattern of Fetal Loss

Data showing fetal deaths by 4-week intervals of gestation period were assembled for 1939, 1944, and 1950 to demonstrate by narrower

Figure 1. Ratio of reported fetal deaths to 1,000 live births, by period of gestation, New York City, 1937-51.

subdivisions of fetal life the improvement in reporting (table 2). Little success can be seen in obtaining reports of abortions during the first month. Because of the failure of the woman to seek medical attention or at times even to suspect that she is pregnant and the inability of the physician to diagnose pregnancy readily by the end of the first month, it is impossible to expect any approach to completeness of report-

ing for this period. Similar circumstances probably preclude complete reporting at even later periods.

Reported fetal deaths for the 4-week intervals subsequent to the first interval, however, have in turn trebled, quintupled, quadrupled, and doubled since 1939. Reported deaths at 20 to 23 weeks' gestation increased 55 percent between 1939 and 1950. For later intervals, smaller increments are noted; and for the period 40 weeks and over, the number of fetal deaths declined. Two opposing forces are in operation: the one—a higher conception rate in recent years and improved reporting of earlier cases—tends to increase the numbers while the other—a decline in pregnancy losses by intra-uterine death (which can be demonstrated for late fetal deaths although not for early ones)—tends to decrease the numbers. The relative importance of the several groups to the total numbers of reported fetal deaths is shown in table 2 by percentage distributions.

The pattern of fetal deaths by period of gestation as a function of the number of females of child-bearing age was investigated although it was recognized that division of the numbers by a different constant would change the picture little. The rate per 100,000 females aged 15 to 44 years was calculated for each gestation

Table 2. Fetal deaths reported in New York City, by period of gestation, 1939, 1944, and 1950

interval for the years 1939 and 1950. The results are given in table 3 and figure 2.

Possible Extent of Fetal Loss

The fairly smooth curve produced by the fetal death rates per 100,000 females beginning with that for 8 to 11 weeks' gestation implies that, were full reports available for deaths at less than 8 weeks' gestation, a J-shaped curve might result for the entire range. Projection of a curve fitted to the data beyond the seventh week provides an estimated fetal loss of 528 per 100,000 females in the selected age group for the 4-to-7-week interval and 909 per 100,000 for the 0-to-3-week interval. (Compare these with the corresponding rates of 112 and 4.4 derived from reported fetal deaths.)

If this conjecture be accepted as appropriate, a total fetal loss rate of more than 2,100 per 100,000 females 15 to 44 years is obtained. With a live birth rate of 7,900, a total pregnancy rate of 10,000 is derived. It may be estimated, then, that 10 percent of the female population aged 15 to 44 years conceives in the course of a year, not considering repeated conceptions, which are of course possible. A closely similar estimate of the pregnancy or conception rate is deduced if the published estimate of deficiency (2), approximately 50 percent, is applied to the known fetal loss rate. If these estimates could be demonstrated to be true, it would mean that about 20 percent of pregnancies result in loss of the fetus and 80 percent in live births at the present time.

Disposal of Fetuses

A problem which occasionally arose prior to 1947 had to do with the disposal of fetuses. It must be remembered that a large proportion of the reports submitted to the New York City Department of Health are based only upon pathological examination of tissue recovered at curettage or other operative intervention—about 50 percent currently refer to fetal death before the twelfth week. However, when macroscopically identifiable fetuses are recovered, two factors should be considered: the wishes of the parents and the usual practices involving the disposal of dead bodies. Provisions had to be

made, therefore, for direction from a parent as to the manner of disposal and for a permit from the health department when a certain specified period of gestation had elapsed before termination of the pregnancy. The "critical fetal age" was set at 16 weeks of gestation after long consideration and consultation with religious authorities. A pertinent paragraph was added to the sanitary code at the time of the 1947 revision:

"A fetus as defined in this section may be kept for anatomical purposes and/or disposed of by the person in professional attendance, with the consent of a parent, without a permit from the department of health provided a report of the fetal death has been made as required herein and provided, further, that not more than sixteen (16) weeks of gestation elapsed before the delivery. Whenever a parent or parents have specified that a dead fetus shall be buried, regardless of the period of gestation, or whenever the fetus has reached the sixteenth week of gestation, the fetus shall not be disposed of without a permit from the department of health."

The increase in the number of permits for disposal of fetuses has been relatively small as a result of these stipulations, and the registration offices in the city have not been overburdened by the obligation.

Cooperation and Controls

Obtaining reports of early fetal deaths rests largely upon convincing the physicians in the community of the value of such reports. Since the chance of getting reports of very early abortions at home is virtually nil, efforts should be concentrated upon hospitals, where postabortal patients needing attention and those submitting to therapeutic abortions will be gathered.

One large factor in the success of New York City is the fact that filing of reports of vital events occurring in hospitals or on hospital ambulance services is primarily the responsibility of the superintendents of the hospitals. This immediately reduces the control program, for there is understandably less effort to enforce reporting among some 200 hospital superintendents than among the much larger number of physicians practicing in these hospitals. Even considering that home cases must still be managed on an individual basis, concentration on the hospital group reduces the problem by an appreciable margin. Ability to utilize specific control measures, however, depends upon the auspices of hospital operation.

In a recent paper by Baumgartner and her colleagues (2), it was shown that reporting of fetal deaths from proprietary institutions was more complete than from other types of institutions. The reason is not obscure. These hospitals are licensed by the city, and the city department of hospitals is the inspecting agency which determines whether a license shall be issued or an annual renewal be granted. One of the criteria used for assessing the adequacy of hospital operation is the completeness of reporting of fetal deaths occurring or diagnosed in a hospital. Hospital charts are examined by inspectors of the department of hospitals, and lists of cases are searched against the indexes of the health department's bureau of records and statistics to determine whether fetal death certificates have been filed. Continued failure to file such records can be grounds for refusal to renew a license. This practice has provided an effective control over reporting from proprietary hospitals.

In municipal institutions, professional staff turnover makes it difficult to rely upon professional staff to initiate reports, especially when

Figure 2. Rate of reported fetal deaths per 100,000 females aged 15 to 44 years, New York City, 1939 and 1950.

such reports are based on requirements which differ from those which hold generally. Persons familiar with New York State law regarding reporting of fetal deaths, or that of any other area, cannot be expected to know local requirements unless specifically instructed. In the turmoil of introducing new staff, reporting of fetal deaths will be considered a relatively minor matter; therefore, other means than instruction of professional staff must be devised for continuing complete reporting.

Following the analysis of reporting of fetal deaths previously cited (2), the reporting of fetal deaths in municipal institutions was discussed with the director of the medical statistics and records service of the department of hospitals. As a result, the commissioner of hospitals approved an addition to the "Manual of Administrative Procedures" of that department, defining the situations where reports are required, outlining the reporting procedures, and prescribing follow-up measures by the hospital

record room to assure that reports are made.

Results of this order were evident immediately. In one municipal institution the number of fetal deaths increased from 68 in one year to 484 in the next while the number of live births in this institution remained relatively constant and the gynecological service showed no appreciable rise in number of patients. Obviously, fetal deaths had not been properly reported in previous years.

Direct control measures, such as exist with proprietary and municipal hospitals, are not available for use with voluntary, State, and Federal institutions. Efforts to obtain cooperation must be handled either indirectly or individually. An administrative officer of one of the larger institutions evinced some surprise not long ago to discover that stillbirths less than 20 weeks had to be reported! Now, the manual for that hospital includes such statements as: "In all cases where there is any product of conception, the doctor will fill out a report of birth. . . . All products of conception under 500 grams will be sent to the pathology laboratory. . . ."

Analysis of Fetal Death Statistics

Brief reference should be made to the influence of reporting requirements upon certain vital statistics data and upon interpretation of these data.

Infant Mortality

That reporting requirements have an influence on the infant mortality rate is well known. However, the degree to which infant deaths may be understated needs emphasis. For example, 36 infant deaths (under 1 week of age) at less than 20 weeks' gestation age were reported in 1949, and 74 such infant deaths were reported in 1950. There were 294 and 329 such infant deaths at less than 24 weeks of gestation age reported in these 2 years. One wonders what would have happened to these cases if reports of fetal deaths had been required only after 20 or more weeks' gestation had elapsed. It is not illogical to surmise that infant deaths at such an early gestation age might have been classed as stillbirths, and no report made if stillbirths need not be reported. But the cited 329 infant deaths

in 1950 comprised 8.5 percent of the total infant deaths. Investigation of mortality among premature would certainly be hampered if such cases were not reported.

The completeness of registration of fetal deaths close to the minimum period of reporting is questionable when an arbitrary gestation limit is stipulated. Resolving whether a fetus is 19 or 20 weeks' gestation age may be uncertain at best and is likely to be decided in favor of the answer which does not require reporting. It can be concluded that statistics on both infant deaths and fetal deaths will be based upon more nearly complete data for any specific period of gestation if all terminated pregnancies must be reported.

Whites and Nonwhites

Wide differentials have been found in fetal death statistics between whites and nonwhites. However, as has already been pointed out, the bulk of reports of early fetal deaths is obtained from patients in hospitals, and very early fetal deaths are unlikely to be reported, especially in the absence of medical care. That nonwhites receive less medical care than whites will not be argued. (Of the 11,206 fetal deaths reported in 1949 as white, 411 were reported following dilatation and curettage; of 3,249 reported as nonwhite, only 14 were such cases. The comparative incidence of such cases is therefore 36.7 to 4.3 per 1,000 fetal deaths.) This factor alone makes hazardous any comparison between the two groups as to incidence of fetal deaths or other analytical areas.

Complications of Pregnancy

The total incidence of reported complications increases with lower fetal age at delivery except among nonwhites. The question naturally arises, of course: Is incidence of complications actually lower among nonwhites, or are nonwhites more likely to have only terminal care from physicians who do not know the patient's history and therefore do not report complications to the same extent as for whites?

The analysis of both live birth and fetal death statistics as to complications of pregnancy is hampered by the lack of a commonly accepted definition of a "complication." While one physician may report any concurrent medi-

cal condition in the mother as a complication, another physician may consider such a condition, which is well controlled and causing no difficulty in management of the patient, as of no consequence and thus not reportable. The statisticians need clinical advice as to the point of view which should be adopted and recommended to physicians.

Summary and Conclusions

The reporting of fetal deaths has improved remarkably and steadily in New York City during the past 12 years. There is, however, a group of unknown size which is unlikely ever to be reported, namely, those which are unrecognized as termination of an early pregnancy and those which terminate without requiring or receiving medical attention.

The increase in the number of fetal deaths reported in New York City has been caused entirely by the increase in reported fetal deaths of less than 20 weeks' gestation. Little change has occurred in the ratio to live births for those of 20 to 27 weeks' gestation, and the ratio for those of 28 weeks' and over has decreased.

The problem of disposing of young fetuses, the different approaches to various hospital groups in attempting to obtain more nearly com-

plete reporting, and the influence of incomplete reporting on analysis of statistics have been discussed.

Certain conclusions pertinent to the WHO recommendations may be drawn:

1. Required reporting of all recognized fetal deaths will provide more nearly complete statistical data regarding pregnancies terminating at the twentieth week of gestation or later than the required reporting of fetal deaths only after such a period.

2. The earlier the pregnancy terminates, the less is the likelihood of obtaining a report of the event, regardless of reporting requirements.

3. Lack of medical or hospital care in any particular group of the population will make difficult the interpretation of statistics resulting from the reports.

Evaluation of Cancer in Connecticut, 1949

The Connecticut State Health Department reports 8,782 persons with active cancer at some time during 1949. Connecticut's cancer rate for that year was 443.5 per 100,000 population.

The report shows a downward trend in female cancer deaths, as shown by age-adjusted rates, and an upward trend in male cancer deaths until 1949, when the rates for males dropped.

Age specific incidence rates for females were higher than those for males from 15-54 years of age. But among children under 5, cancer was more prevalent in boys than in girls, and in persons over 60, the disease was more prevalent among men than among women.

Reporting of cancer in Connecticut is not required by law. The detailed data on cancer incidence, prevalence, and mortality were gathered through the voluntary register maintained by the division of cancer and other chronic diseases of the State health department. Connecticut hospitals, out-of-state hospitals, and the bureau of vital statistics of the State health department were the three sources of reports sent to the registry. Eighty-five percent of the cancer cases diagnosed in 1949 were reported by hospitals.

Construction of Hospitals, Health Centers, and Other Health Facilities, 1951-52

By WESLEY E. GILBERTSON, B.S.E.E., M.P.H., and HAROLD A. KAHN, M.A.

MORE than a quarter of last year's hospital construction costs were in projects designed to improve existing facilities without addition of any new bed capacity to the Nation's total. This and many of the other facts regarding health facility construction reported in this paper are a byproduct of Public Health Service claimant agency responsibilities under the Controlled Materials Plan (1).

In previous years, figures indicating the gross dollar value of hospital and institutional construction put in place have been obtained through reports issued by the Bureau of Labor Statistics and the Department of Commerce. Material published by the American Medical Association and the American Hospital Association contains data on existing hospitals and their bed capacity. More recently the reports issued by the Public Health Service in connection with the Hospital Survey and Construction Program (Hill-Burton Act) have provided comparative statistics with respect to existing hospital beds and requirements, based on State agency classification and analysis.

In addition to these sources, during the past year a wealth of detailed data have become available from applications submitted to the Public Health Service requesting authority to begin construction of hospitals and other health

facilities and for allocations of critical materials under the Controlled Materials Plan. From these data, until now not available, it is possible to obtain a much better understanding of the nature and extent of the total construction effort currently being expended in the area of hospitals, health centers, clinics, nursing and convalescent homes, rehabilitation centers, nursing schools, medical research laboratories and related health and medical construction. Broader use of the information will be a valuable byproduct of the claimant agency program.

Construction Volume, 1947-52

Since January 1947, hospital and institutional construction has increased rapidly, as shown in figure 1. The exclusion of Veterans Administration hospital construction and the adjustment of all dollar values to a constant base makes it possible to compare the relative physical volume of health construction for the general civilian population over a 5½-year period.

In the civilian field, general health and medical care building more than tripled in volume from January 1947 through June 1952. There was a leveling off in 1950 of the steep upward trend, and the rate has continued since on an approximate plateau, except for a peak in the middle of 1951. Although the shortages of steel, copper, and aluminum have required careful use and allocation of these critical materials, the Nation continued to add to its health facilities at a near record rate through the first year of the Controlled Materials Plan.

Mr. Gilbertson is chief of the Division of Civilian Health Requirements, Public Health Service, and Mr. Kahn is chief of the analysis and reports branch of the division.

Division of Construction Pie

Construction of health and medical care facilities totaled \$773 million during the fiscal year July 1, 1951, through June 30, 1952. This represented 2.5 percent of the total national \$31 billion annual construction volume. Other segments of special interest to the health profession are: sewer and water—\$669 million, or 2.2 percent of the total; educational—\$1.9 billion (6.1 percent); residential—\$11.2 billion (36.3 percent). Figure 2 shows the proportions assumed by these and other classifications in the building industry and, in turn, the division between the major elements within the area of health and medical care. The “pie” section of this chart distributes the aggregate cost, as cited in the estimates on CMP applications; this covers all the health facility construction projects of the various types for which permits for construction to begin July 1951 through June 1952 were requested from the Division of Civilian Health Requirements, Public Health Service. Small construction projects requiring no more than 5 tons of carbon steel and 250 pounds of copper per quarter could be self-authorized under CMP regulations and are not represented on the chart. The same thing applies to requirements for maintenance, repairs, and operations not exceeding 30 percent per quarter of the rate for the calendar year 1952.

The most striking fact shown by this chart is that seven-tenths, 71 percent, of the total expenditure is for additions and remodeling of in-patient institutions and only slightly more than one-fifth, 22 percent, is going into completely new in-patient medical care facilities. The remainder is for other miscellaneous health facilities. This circumstance is undoubtedly known to persons who are familiar with national hospital building trends, but it may be surprising to others.

The preponderance of activity on general hospitals (new—18 percent; additions and remodeling—47 percent; total—65 percent) as compared with the more specialized institutions is not unexpected. However, it does not indicate the relative needs in each category. Another interesting comparison shows that the proportion of additions and remodeling to new institutions averages about three to one, except for mental facilities, for which it is ten to one.

The number of projects in various categories, the estimated cost, and their materials requirements are listed in table 1.

Materials Estimates and Project Needs

For each calendar quarter, the materials requirements for health facilities, as for all other construction and production, must be estimated and justified to the Defense Production Admin-

Glossary of Terms

- Cost of Construction*—includes fixed equipment but excludes land cost.
- New Start*—a construction project for which a permit to begin is required. Not necessarily a new institution.
- Project*—a unit of construction activity for which a separate permit is requested.
- Institutional Construction*—Relates to prisons, orphanages, etc. The volume of this type of construction is included with hospital construction in many published statistics. It is believed to be about 5 percent of the “hospital and institutional” total.

¹ Excluding projects later withdrawn by their sponsors. ² Includes nursing homes. ³ Less than 500 pounds.
⁴ The average cost per ton of increased capacity, based on 24-hour operation, was about \$3,000.

istration. Since the supplies of steel, copper, and aluminum were only 69, 65, and 64 percent, respectively, of the total amounts claimant agencies requested during the year, the Defense Production Administration had to apportion the available supplies in accordance with its standards of essentiality. Table 2 lists the

amounts that were requested and granted by calendar quarter for each of the controlled materials used in hospital and health facility construction. The volume of materials given in this table was required for completion of projects that had started prior to CMP as well as for the needs of the "new starts."

Figure 2. Total United States construction volume (in thousands of dollars) and relative dollar volume of hospital and health facility projects proposed to start July 1951 through June 1952.

	0.8		3.0		

Source for bar chart data: *Construction*, December 1951 and June 1952, and unpublished data, Bureau of Labor Statistics

The record shows that steel requests were reduced by an average of about one-fourth. Copper-brass mill (plumbing) requirements were cut by nearly one-half and copper wire by a third. The aluminum estimates, which were

also reduced almost by one-half, are not considered as vital to construction. This treatment of materials requests for civilian health facility construction should not be compared with the relationship of total supply to total request

Table 2. Controlled materials requested from the Defense Production Administration for construction of civilian health facilities and the amount and percent allocated

without considering that military, atomic energy, and related requirements were granted at 100 percent. With this in mind, it is accurate to state that civilian health facility construction requests properly received preferred treatment from the Defense Production Administration.

If the reduced allotments received from the Defense Production Administration had been passed directly on to hospital and health facility projects, about 400 applications would have been rejected. Instead, each application was screened carefully, with the assistance of the State hospital agencies and the regional offices and the available material was distributed as equitably as possible among all eligible health facility projects. At the same time, an educational campaign was directed toward the conservation of critical materials. As a result, all of the projects falling within our claimant jurisdiction for the first three quarters have been approved and less than 10 projects for second quarter 1952 were pending September 1, 1952 (fig. 3).

The process of analyzing CMP applications is an important and critical responsibility. Months and years of planning and hopes are

represented by each document. Every effort has been made to take into consideration any special circumstances which require unusual amounts of materials. We believe that, in general, conservation efforts have been successful in the sense that materials were stretched over additional projects without sacrificing soundness of construction. A possible exception is in the partial substitution of less permanent materials for copper and brass plumbing lines during the latter part of the year. In this connection, the Public Health Service urged that the available copper and brass be used in the more inaccessible locations of structures where any future replacement would be difficult and expensive.

Maintenance of Standards

Equally as important as completely new facilities to students of medical care economics is the expenditure—in dollars and materials—that is required to avoid deterioration. This expenditure is represented by the sum of those repairs and renovations needed to maintain existing beds in operation and in an acceptable status. Included are projects for structural renovation, rewiring, sprinkler systems, fire es-

capex, reroofing, and the like. Some of the projects stem from fire and safety inspections and mandatory orders to correct hazardous conditions. Minor repairs which were self-authorized are excluded from this tabulation. If they were added, they would raise the total number of projects considerably, but, due to their nature, would not proportionately affect the total expenditures or materials requirements.

Of the total number of hospital and nursing home projects approved during the past year, more than one-half (51 percent) did not add beds. Over one-quarter (27 percent) of the cost was for nonbed projects. Table 3 shows the funds and materials required by the three significant "R's"—repair, remodeling, renovation—for various types of facilities during the past year.

Nearly 3 out of every 10 dollars expended for hospital and nursing home construction—about \$200 million last year—went into improvements needed to maintain, but not add, beds. And this amount was not all that is really needed for repairs and renovation. Undoubtedly many beds slipped into an unacceptable status because the necessary investment was not made to overcome obsolescence.

Hill-Burton Stimulus

Much of the credit for the increased pace of hospital and other health facility construction

Figure 3. Requests for permits to begin health facility construction, by quarters, July 1951 through June 1952.

during calendar years 1948 and 1949, as well as the current high level shown in figure 1, can be attributed to the stimulating effect of Hill-Burton grants. Thirty-two percent of the cost of all hospital and health facility construction authorized to begin construction from July 1,

Table 3. Percent of projects, construction cost, and materials required to maintain existing in-patient care facilities without adding beds to Nation's total, July 1951 to June 1952, inclusive

1951, through June 30, 1952, was for projects authorized by the Hill-Burton program. Thirteen percent of the total cost was represented by direct Federal funds. The greater volume of Hill-Burton assistance to general hospitals than other facilities is shown in figure 4.

Analysis of Bed Need

A significant element in the Hill-Burton program is the analysis of bed need by the responsible State agencies. To qualify for Federal

grants under the act, a State is required to develop an annual plan approved by the Public Health Service. Each plan includes an inventory of all available non-Federally operated facilities, in terms of "acceptable" and "not-acceptable," and an estimate of the beds and facilities needed to increase the resources of the State to the level authorized by the act. These total bed needs are the number required to meet the minimum standards adopted under the act. They are therefore not necessarily the ultimate goals.

Table 4. In-patient care facilities requested for construction start July 1951 to June 1952, showing beds to be added relative to need, by Federal Security Regions for general hospitals and United States total for other facilities

Table 4 shows, by State, the available existing and the "total needed" general hospital beds as reported January 1, 1952, by the Division of Hospital Facilities, Public Health Service, as compared with the number of beds which will be added upon completion of the requested construction starts for the period July 1951 through June 1952. Similar data, when available, are also included in this table for other types of health facilities omitting the geographic detail for individual States and regions. The 2-page chart illustrates the need as compared with the

current rate of bed construction, neglecting the obsolescence that is not being met through renovation.

The most notable observation to be made from these data is that the current high amount of construction will not close the gap between beds needed and beds existing for general hospitals in less than 7 years; for mental and tuberculosis hospitals in less than 25 years; and for chronic hospitals in less than 170 years! None of these time estimates make provision for an expanding population, for uncorrected

obsolescence over future years, or for what may be of primary importance—changes in patterns of hospital usage. Another interesting observation is that no geographic or sectional pattern is evident. There are wide variations between individual States, but the differences are as likely to occur between neighboring States as those separated by half the continent.

Ownership of Projects

Table 5 shows the distribution of construction cost into three categories of ownership: public, private nonprofit, and proprietary for various groups of health facilities. During the year, 44 percent of the construction cost of new starts was on publicly owned facilities, 55 percent on privately owned nonprofit, and 1 percent on proprietary projects.

Summary

1. Civilian health facility construction has not been seriously set back under the controlled materials plan.

Table 5. Percentage distribution of construction cost by type of ownership for requested new starts, July 1951 through June 1952

Type of facility	Percentage of construction cost		
	Public	Private nonprofit	Proprietary
Total.....	43.6	54.9	1.5
Total hospitals and nursing homes.....	40.9	58.0	1.1
General hospitals.....	29.0	69.7	1.3
Mental hospitals.....	88.1	11.7	.2
Tuberculosis hospitals.....	87.4	11.1	1.6
Chronic hospitals.....	21.6	78.4	0
Other hospitals.....	28.6	70.4	.9
Nursing homes.....	24.2	72.7	3.0
Health centers.....	95.1	3.3	1.6
Clinics.....	8.5	46.5	45.1
Incinerators.....	100.0	0	0
Other.....	76.8	23.2	0

2. Construction volume for additions to and remodeling of hospitals far exceeded the volume of new hospital construction.

3. Two-thirds of all construction volume in the civilian health field was for general hospitals.

4. Although given preferred treatment by the Defense Production Administration, civilian health facilities were allocated much smaller quantities of materials than needed. A policy of conservation was adopted to "spread" the available materials and prevent an appreciable number of disapproved applications.

5. More than one-fourth of in-patient construction volume was for nonbed projects.

6. One-third of all health facility construction received Hill-Burton assistance.

7. The number of new beds of all types started during the year was about 45,000.

8. Forty-four percent of health construction was publicly owned; 55 percent was privately owned by nonprofit organizations; and 1 percent was privately owned and operated for profit.

Obstacles to Eradicating Congenital Syphilis

By JOHN J. WRIGHT, M.D., M.P.H., CECIL G. SHEPS, M.D., M.P.H., EUGENE E. TAYLOR, M.D., M.P.H.,
and ALICE J. GIFFORD, A.B., M.N.

CONGENITAL syphilis is one of the most completely preventable of all serious diseases. Its epidemiology and pathogenesis are so thoroughly understood and available methods of prevention, diagnosis, and treatment are potentially so excellent that eradication seems to be a practical goal.

There has been much progress toward this goal. In fact, Nelson and Struve (1), on the basis of a careful study in Baltimore, conclude that the number of infants born with syphilis probably cannot be reduced any further—until there is less syphilis among adults or until more mothers seek and obtain early prenatal care.

This conclusion may be applicable to many communities. However, it is likely that in others the effectiveness of control activities aimed directly at congenital syphilis could be improved relatively cheaply. For this reason a brief review of the general problem seems indicated. A few of the most pertinent and recent papers are cited, and findings of a recent study in North Carolina are summarized in some detail.

Epidemiology

Syphilis may be transmitted from mother to fetus between the fifth month of pregnancy and

the day of delivery. The father does not transmit infection to his unborn child except indirectly when he is the source of the mother's infection. If a pregnant woman has untreated primary or secondary syphilis the fetus will be infected in almost 100 percent of cases. Chances for infection of the fetus decrease with increasing duration of the maternal infection.

Clinical Aspects

Penicillin treatment of the pregnant woman is extremely effective in the prevention of congenital syphilis. Once adequate treatment has been received, it is no longer considered necessary to re-treat the mother during every pregnancy, if she can be followed closely (2).

Diagnosis of syphilis in infancy is often difficult. There may be no physical signs of the disease. The serologic test for syphilis (STS) is often negative until 3 or 4 months of age. On the other hand, nonsyphilitic infants of syphilitic mothers (usually with treated or old infections) may be seropositive from birth until 3 months of age because of transplacental transfer of maternal reagin. Nonsyphilitic infants also may develop biological false positive serologic tests during the fifth month of life or after. This is thought to be due usually to an immunization procedure or an acute infection (3).

Penicillin is the agent of choice for the treatment of congenital syphilis. The patient is more likely to become seronegative if he is treated before age 2 and preferably in the first 6 months of life. Interstitial keratitis remains a difficult complication to prevent or to treat.

Dr. Wright is a professor of public health administration in the School of Public Health, University of North Carolina. Dr. Sheps is director, and Dr. Taylor is a research associate in the program planning section of the division of health affairs of the university. Mrs. Gifford is professor of community nursing in the School of Nursing.

Recently cortisone has been used as an adjuvant in treatment (2).

Incidence and Prevalence

There are a number of defects in the statistical indexes currently used for the measurement of congenital syphilis in a population (1, 4).

The rate of discovery of infected children age 0-1 per 1,000 live births is one index of trend. This should be made specific for race. In comparing rates, allowances must be made for differences in the age distribution of the mothers, and for differences in the effectiveness of case finding among infants.

For the study of trends over long periods of time, attack rates can be obtained by assigning cases discovered at any age to the year of birth before computations are made. To obtain an accurate rate for any one year it is necessary to revise the rate over the period of the following several years.

At present, about 13,000 cases of congenital syphilis are reported each year in the continental United States, and it is estimated that there is a residue of 100,000 undiscovered cases in our child population, age 0-10. Congenital syphilis is primarily a regional problem. During 1941-49, one-half of all cases were reported from 13 southern States which together include only about one-fourth of the total population of the country (5).

The total number of reported cases has remained constant since 1944. In fiscal year 1951, 6.4 percent of reported cases were age 0-1 at time of discovery, 7.2 percent were age 1-4, 17.1 percent were age 5-9, 0.3 percent were under 10 but of unknown age, and 69 percent were age 10 and above (6). These are the first figures on the age distribution of reported cases that have been available for the country as a whole. It is not known whether this age distribution has been constant from year to year or has been changing. Therefore, the number of children now being born with syphilis cannot be estimated.

The residue of undiscovered cases may be shrinking because of case-finding efforts and because fewer infected infants are born. If so, the constant level of reported cases could be accounted for by the success of the case-finding

program among older children. However, it is possible that in at least some communities, the residue of undiscovered cases is being at least partially replenished by significant numbers of syphilitic newborn infants, few of whom are diagnosed in infancy.

Missed Control Opportunities

The North Carolina Syphilis Studies has developed a simple classification of the types of opportunities which professional health workers have for bringing about the eradication of congenital syphilis. In studying histories of cases discovered in any community, opportunities which have been missed can be tabulated. This will reveal weaknesses of the local control program and suggest where emphasis needs to be placed. Similar classifications could be developed for the study of problems in the control of acquired syphilis and other diseases of public health importance.

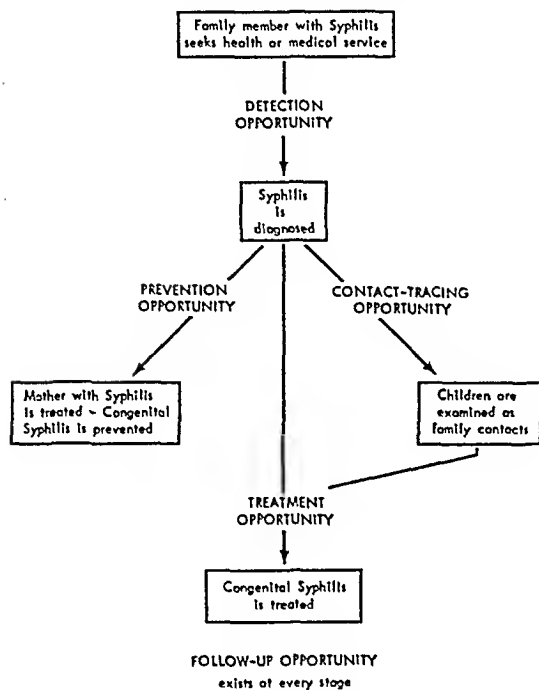

Each instance in which there was an opportunity to prevent congenital syphilis or to treat is at an earlier date is counted as a missed "control opportunity." Control opportunities are classified into five types: detection; prevention; contact tracing; treatment; and follow-up (see figure).

Assume that there is a family consisting of mother, father, and two children. Both parents have had syphilis and both children have had congenital syphilis. All members of the family have now received adequate treatment. The family history is to be reviewed beginning at the time when infection first entered the family and ending at the time when all members of the family had finally been treated.

If the history showed that any family member was given health or medical service at a time when syphilis could have been detected by STS, history or physical examination, or both, this event will be considered a detection opportunity. There may or may not have been a clue suggesting syphilis, but syphilis would have been detected if suspected.

If one member of the family was found to have syphilis, other types of control opportunities were immediately presented, depending on the circumstances.

If the mother was found to have syphilis

before either or both children were born, there was a "prevention opportunity." If the mother had been given adequate antisyphilitic treatment during or before pregnancy, congenital syphilis could have been prevented.

If, after the birth of a congenital syphilitic child, the mother, father, or other child was found to have syphilis, there was a "contact-tracing opportunity."

If either child was found to have syphilis, there was a "treatment opportunity." Again the indicated action here was skillful and adequate administration of antisyphilitic drugs.

Finally, "follow-up opportunities" occurred at any point where follow-up was needed to keep the family under observation until needed services had been given.

This classification was used in the study of 60 cases of congenital syphilis discovered in four North Carolina counties during the period 1946-50.

Ages of the 60 patients at time of final discovery ranged from 1 month to 24 years with a median age of 8 years. Their histories demonstrate weaknesses of control programs in years past. During recent years momentous changes have taken place in control methods.

Hence it cannot be assumed that present weaknesses are the same as those demonstrated. On the other hand, it cannot be assumed that they are different. The failures of today's control efforts will not all be revealed for many years hence.

Data for family histories were collected as follows:

Health department and hospital records on family members were reviewed and abstracted.

Mothers and other responsible family members were interviewed personally.

Private physicians were interviewed or sent letters of inquiry.

The register of STS reports and birth reports maintained for the four counties by the North Carolina Syphilis Studies was searched for data on each family.

Altogether, for the 60 cases studied in this fashion, 348 missed control opportunities were identified. The least number for any case was 1; the greatest number was 18. The table presents the number and relative frequency with which each type of control opportunity had been missed.

Number and types of control opportunities missed prior to adequate treatment of 60 cases of congenital syphilis

Types of control opportunity	Number	Percent
Detection opportunities.....	199	57.2
Prevention opportunities.....	12	3.4
Contact-tracing opportunities.....	85	24.4
Follow-up opportunities.....	46	13.2
Treatment opportunities.....	6	1.7
Total.....	348	99.9

Slightly more than one-half of the total (57.2 percent) were detection opportunities, about one-fourth (24.4 percent) were contact-tracing opportunities, and about one-eighth (13.2 percent) were follow-up opportunities. In only 18 instances did the difficulty center around the problems of drug administration (missed prevention and treatment opportunities). The usual difficulty was that a mother or child would fail to complete an arsenical-bismuth schedule of treatment despite definite efforts at follow-

up. With penicillin therapy, this type of problem should be even more rare.

Detection Opportunities

Detection opportunities had been overlooked in the following ways:

1. Mothers were allowed to go through pregnancy and delivery without an STS having been done. Reasons were that the mother received no prenatal care at all, the physician did no STS as part of prenatal care or at time of delivery, or a midwife attendant failed to have her patient examined at a physician's office or health department clinic.

The prenatal STS is universally recognized as an indispensable technique in congenital syphilis control. Much faith has been placed in the value of "prenatal blood-testing laws." As of May 1950, 40 States had such laws (5).

There is little accurate information as to how effective the prenatal laws are when not supplemented by other educational techniques. In a few States, for example, California, studies have indicated that a prenatal STS was done in well over 90 percent of pregnancies (7).

North Carolina's prenatal law went into effect in January 1940. A study was made recently of over 16,000 pregnancies occurring in three rural North Carolina counties during 1941-49. An STS during pregnancy or at time of delivery had been done in only 54 percent of pregnancies. For women hospitalized for delivery the figure was 69 percent; of women delivered at home by physicians, 42 percent were tested; 40 percent of women delivered at home by midwives were tested. Over the period of 9 years, there was only a small increase in the proportion of women receiving tests (unpublished data, North Carolina Syphilis Studies).

The State health department in South Carolina also found in 1948 and 1949 that significant numbers of pregnant women were not being tested despite the prenatal law of 1946. Ball's paper (8) describes how an effective educational campaign based on this study was developed among physicians, midwives, and health department personnel.

2. Mothers were infected after a negative prenatal STS had been obtained.

A maternal infection, reinfection, or relapse

late in pregnancy may be overlooked because of reliance on earlier negative tests. Because of this possibility, some authorities have suggested that at least two prenatal STS should be done routinely—one early in pregnancy and one late in the third trimester or at delivery. However, increasing the number and types of routine diagnostic tests definitely costs both time and money. Also, unless it can be assured that each pregnant woman gets at least one STS, it may be unrealistic to advocate repeat tests as a routine measure. Fiumara (9) makes the practical suggestion that the STS be repeated late in pregnancy if the mother is single, divorced, or separated, has a past history of any venereal disease, or is thought to have been promiscuous.

3. Parents and children were given miscellaneous health or medical services and syphilis could have been detected had specific examinations been made.

Usually the doctor or nurse had no reason to suspect syphilis. It would not be fair to say that a routine STS should have been done in each of these instances. However, in many instances vital information was on record that should have caused the doctor or nurse to suspect syphilis, but this information was not available and was not even known to exist. The reason for this was that responsibility for the family's health services had been divided among different professional workers who were not in close communication. The needed records (containing data on previous diagnosis or suspicion of syphilis in the family) were in other departments of the same agency or in other agencies or offices.

4. Only very rarely was evidence found that detection opportunities had been missed through failure to recognize clinical signs of congenital syphilis.

Some congenital syphilitic children show no definite signs or stigmata of their disease. The authors feel it is questionable whether doctors or nurses, other than venereologists, should try to keep the less common signs and stigmata in mind as an aid to case finding. It would be of much more value if doctors and nurses could be familiar with the syphilis history of the mother of each child served. Unfortunately, this objective may be very difficult to achieve.

Contact-tracing Opportunities

Usually no explanation could be found as to why contact-tracing opportunities had been missed. In some instances, the physician or nurse may simply have been in the habit of concentrating on the individual patient's needs, to the exclusion of the family's needs. Occasionally, a parent's statement that a child was well was accepted in lieu of an actual examination. In still other instances, known infection of the father or known congenital infection of a sibling was overlooked as a clue pointing to an undiscovered case. (Although the infected mother is the most important clue, she may have been successfully treated and have a negative STS. Or the child may not be living with his mother. Clues presented by other infected family members thus can be of vital importance.)

In studying a series of 50 cases of congenital syphilis diagnosed in various parts of the country, Bauer and Shortal (10) also found that children were often not examined as family contacts when the mother was found to have congenital syphilis.

Follow-up Opportunities

The most frequent type of situation in which follow-up opportunities were missed was one in which a family member was suspected of having syphilis, but the diagnosis was never completed. For example, a blood test would be taken, the report would be positive, the family member would not return for the report, and no follow-up effort would be made. In other instances the family was lost from observation after mother or child had begun treatment; again, no follow-up effort was made. Finally, some families were lost in the process of referral from one institution or private physician to another. These families were not followed to the point where the referring institution or physician knew that the family member had reached his destination and received the service for which he was referred. In many of these instances, parents and children were at least partially at fault for not cooperating with their medical advisers. However, "lack of cooperation" would at best be only a partial explanation, since action on the part of the private

physician or health department was clearly indicated.

Integration vs. Fragmentation of Services

A study done in Boston several years ago demonstrated that fragmentation of health services to families resulted in serious problems in congenital syphilis control (11). The present study confirmed this.

One likely explanation for omission of contact tracing would be that the health care of the family was not an integral unit. Omission of follow-up suggests that even the health care of the individual was often a series of separate episodes. Detection opportunities sometimes were missed because useful information was scattered among agencies and professional persons who were not in communication.

This is a basic problem, and a solution is needed in attempts to manage a great many diseases other than congenital syphilis. A solution would require coordinative efforts within offices and also between offices. At times, record systems based on individual patients or disease categories rather than on families are a serious handicap and may need to be redesigned. To improve communication between offices, it may be possible to work out arrangements for convenient and ethical exchange of information by health workers serving the same family, for example, the public health nurse and the private physician.

Summary

There has been remarkable progress in the control of congenital syphilis, so much so that in some areas it is doubtful whether expansion of programs can be justified. However, in other areas the effectiveness of control efforts can probably be increased with little added expense.

Weaknesses of control programs can be studied by reviewing histories of recently treated cases and tabulating all control opportunities which were missed prior to diagnosis, a technique that could also be modified for use in the study of other venereal disease control problems.

Using this technique, a careful study was

made of 60 cases of congenital syphilis brought to treatment in a four-county area in North Carolina.

Judging from this series of cases, one would expect to find in many communities that more emphasis was needed on the following activities:

1. Making the initial step of detecting a case of syphilis in a family.
2. Following the chain of infection until all infected family members were located.
3. Keeping the family under observation until the possibility of future congenital infections was eliminated and any child already infected was treated.

The actual process of administering anti-syphilitic treatment to infected mothers or children presents only minor problems today.

In some areas, many women still go through pregnancy and delivery without being given a serologic test for syphilis, despite laws requiring this procedure.

Mothers may be infected late in pregnancy with resultant infection of the fetus. This dangerous possibility may be overlooked if an earlier prenatal STS was negative.

Fragmented, poorly integrated health and medical services to syphilitic families appear to present a basic problem to which there is no ready or certain solution.

The study was supported jointly by the Division of Venereal Disease of the Public Health Service, the North Carolina State Board of Health, and the School of Public Health of the University of North Carolina.

Children's Bureau Appointment

The appointment of Dr. Helen Witmer, Ph.D., as director of its division of research was announced in September by the Children's Bureau of the Social Security Administration, Federal Security Agency. A teacher, author, and a participant in many social research studies and projects, Dr. Witmer was director of fact-finding for the Midcentury White House Conference on Children and Youth. She directed a study of current mental health promotion programs for the National Institutes of Health, Public Health Service, before joining the staff of the Children's Bureau in 1951.

Influenza Study Program in the United States

By DORLAND J. DAVIS, M.D., Ph.D.

AMONG the major public health problems in infectious diseases, influenza remains one of the most challenging and most important to medical scientists all over the world. Its importance is due not only to the occurrence at long intervals of severe pandemics, but also to the disruption of normal activities by illness and lost time during the less severe outbreaks occurring nearly every year. Much of our knowledge and interest has been stimulated by the experiences in 1918, when approximately 15 million people throughout the world died of influenza, and by the possibility of another such occurrence. But the heavy toll in disability and economic loss every few years, when it occurs in milder form, also makes influenza of major concern to health authorities. This disease has always been of importance to military services, and its control forms a large part of their preventive medical programs.

Characteristic of influenza are the explosive outbreaks in which the incidence sometimes involves 25 to 30 percent of a local population over a period of 2 or 3 weeks. Epidemics recur at 2- to 4-year intervals, usually but not always during the winter months. The death rate is ordinarily highest in the aged. Influenza appears in rapid sequence in neighboring communities, though sometimes intervening communi-

ties are spared; and it tends to involve large regions, even continental and world-wide. These are the general features which distinguish influenza sharply from other infectious diseases, and, prior to the identification of the etiological agents, characterized it perhaps more accurately than the clinical picture.

With the first isolation of the specific virus from human cases of clinical influenza in 1933 by Smith, Andrewes, and Laidlaw, new techniques were soon developed for the study of this disease. At present we have a number of laboratory methods for the specific diagnosis of influenza—isolation of the virus by inoculating pharyngeal washings into embryonated eggs or ferrets, complement fixation reactions, and the hemagglutination inhibition test. These methods have undergone several years of trial and now have reached the stage of development and simplicity at which they can be used with confidence by a number of laboratories, and the results can be fairly compared. They have been used extensively on a local scale and particularly in selected groups such as military or institutional populations.

Origin of Program

Since influenza is a world-wide disease, it is necessary to obtain rapidly information of its occurrence from all parts of the world. With the laboratory aids now available, much useful information can be obtained by an international system of reporting based upon specific etiological diagnosis. Such a plan was proposed at the Fourth International Congress for Microbiology in Copenhagen in July 1947. Under the

Dr. Davis is executive secretary of the influenza information center of the WHO Influenza Study Program in the United States and chief of the influenza unit in the National Microbiological Institute, Public Health Service.

upon orship of the World Health Organization, a World Influenza Center was set up at the National Institute for Medical Research, London, to study and analyze newly isolated strains. Subsequently, at the suggestion of the WHO, the Surgeon General of the United States Public Health Service invited the participation of American investigators in the program. The Commission on Influenza of the Armed Forces Epidemiological Board had been maintaining a continuous interest in this problem and had established listening posts and a strain study center some years before. On the advice of the virus and rickettsial study section of the National Institutes of Health, the Surgeon General sponsored a meeting of representatives of the Surgeons General of the Army, Navy, Air Force, and Public Health Service. At the meeting it was decided to build the program in the United States largely around the strain study center and use the existing facilities for investigating influenza.

In 1948 the influenza study program in the United States was activated to obtain and exchange reliable information concerning the occurrence of outbreaks of influenza in the United States and throughout the world, to isolate specific viruses involved, and to study and compare these with respect to their antigenic characteristics. In addition, it was hoped that this information would be useful in determining the effectiveness of current vaccines and in the selection of strains to be used in the vaccines.

Organizational Set-up

The program operates under an advisory committee composed of representatives of the Surgeons General of the Public Health Service, Navy, Army, and Air Force, and the Armed Forces Medical Policy Council of the Department of Defense, and the Bureau of Animal Industry, United States Department of Agriculture, who are responsible for over-all policy.

The actual functions of the program are carried on more or less autonomously by seven regional laboratories in various parts of the United States and one in Puerto Rico. These laboratories, which integrate the program in their respective areas, enlist the assistance of

other laboratories of the area. They distribute specific influenza antigens and anti-serum to their area collaborators, and they identify as influenza virus those agents they or the collaborating laboratories have isolated before the isolates are transmitted to the strain study center.

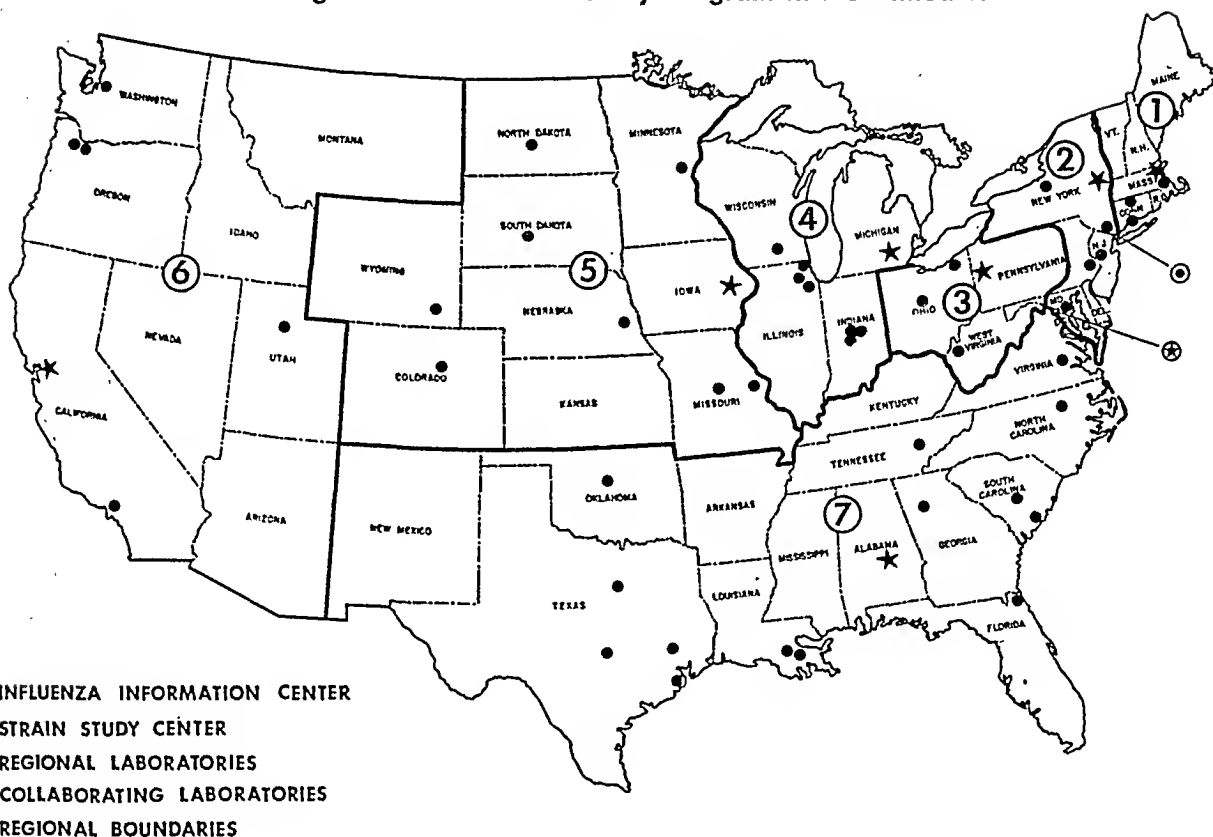

Collaborating area laboratories, selected for each area by the corresponding regional laboratory, serve as lookout posts to report outbreaks of influenza; perform serologic tests with the serum of suspected cases; and, in some cases, isolate virus from patients with influenza. All of these laboratories have been selected on the basis of their interest and particular competence in diagnosis of influenza, and they represent university, hospital, Federal, State, and municipal laboratories.

Information is obtained from the six Army medical laboratories in the United States, other Army medical laboratories in Europe and Japan, the Department of Virus and Rickettsial Diseases of the Army Medical Service Graduate School at the Army Medical Center, Naval medical laboratories at Great Lakes, Ill., and elsewhere, and Public Health Service laboratories at the National Institutes of Health and Communicable Disease Center. The influenza strain study center is located at New York State University Medical Center, Brooklyn, N. Y. Strains of influenza virus newly isolated from patients by regional or other laboratories participating in the program are sent to the strain study center for antigenic analysis.

The influenza information center, located at the National Institutes of Health, Bethesda, Md., is responsible, under the advisory committee, for receiving and disseminating information on outbreaks of influenza and the strains of virus causing these outbreaks; for establishing a coordinated series of strategically distributed regional and area diagnostic or research laboratories for the isolation of new strains of influenza virus; and for aiding in arranging conferences concerned with problems of the program.

World-Wide Circulation

Current reports from the participating laboratories are coordinated with those from State

Numbers indicate study areas

NOTE.—The strain study center is at the State University of New York, Brooklyn, and the influenza information center is at the National Institutes of

Health, Bethesda, Md. A regional laboratory is located in Puerto Rico, and Alaska and Hawaii each have a collaborating laboratory.

epidemiologists and published weekly in the *Communicable Disease Summary* and the *Morbidity and Mortality Weekly Report* of the National Office of Vital Statistics, Public Health Service. These reports are sent to health authorities in the United States and other countries, the World Health Organization, the World Influenza Center in London, and others interested. In unusual circumstances foreign laboratories and centers are informed by cable.

In Canada a similar organization with the same objectives has been in operation and provisions made for exchange of information and study of new strains of virus.

With the development of virus laboratories in the countries of Central and South America, new opportunities are being offered for the collection of additional information of great

importance to our knowledge of the spread of influenza. Plans are being developed by the Regional Office for the Western Hemisphere of the World Health Organization (Pan-American Sanitary Bureau) to initiate an expansion of the program to include all countries of the Western Hemisphere in a coordinated program of influenza reporting and study of newly isolated strains. Such an extension of the present programs in the United States and Canada should greatly enhance the value of the worldwide effort to solve some of the problems in the epidemiology of the disease.

Influenza Occurrence Last Winter

The first indications of influenza during the winter season of 1951-52 were received from Utah, where there was a sharp outbreak of influenzalike disease in the cities of Ogden and

Prova during the latter part of December 1951. Influenza B virus was recovered from the throat washings of two of the cases. Early in January 1952 a report of influenza was received from a military installation in California. Serologic tests identified it as type B. In the middle of January, cases of clinical influenza were reported in the western part of Kentucky, but opportunities for laboratory confirmation were lacking.

During the remainder of January reports of outbreaks of clinical influenza were received from Nevada, California, Oregon, Little Rock, Ark., and from the Naval Training Center, Bainbridge, Md. Subsequent laboratory studies resulted in the isolation of influenza virus type B from cases in Little Rock, and both type B and A' from the Naval Training Center. Throat cultures performed on a large number of cases at Bainbridge revealed the presence of beta hemolytic streptococci in a high proportion also. Serologic studies in California in the civilian population and military installations indicated the infection was type B.

Early in February reports were received of outbreaks of influenzalike disease in Nebraska, Ohio, and Frederick, Md. Influenza virus type B was recovered from cases in Frederick. In military installations in New Mexico, Illinois, and New York there was an increased prevalence of respiratory diseases, and subsequent serologic examination showed a number of positive serologic tests for influenza type B from these places. During the remainder of February influenza confirmed by isolations of virus and serologic tests was reported in Norfolk, Va., Washington, D. C., Indianapolis, Philadelphia, Boston, New York State, South Carolina, and Texas. Reports continued to be received from California, where the disease occurred in numerous areas throughout the State.

In early March, influenza, type B, was confirmed by positive serologic tests of influenza reported from Syracuse, N. Y., and New Haven, Conn.; and in the middle of March influenza type B virus was isolated in Iowa during the course of an outbreak. During the remainder of the month, the disease confirmed by virus isolation was reported from Michigan and New York City. The report from the WHO Influenza Center, Canadian Department of Health

and Welfare, indicated that an outbreak of influenza in Edmonton, Alberta, occurred in the latter part of March. During the latter part of May and early June influenza occurred in Puerto Rico and was diagnosed by serologic studies as type B.

Type B Predominant

It is apparent that influenza type B infection was widely distributed throughout the United States beginning in December and persisting through March and possibly April. The outbreaks appear to be localized, and certain cities and areas seem to have escaped almost entirely. There has been no evidence of a uniform zonal spread of the disease since it appeared simultaneously in widespread areas, often skipping intermediate points between foci. While the disease affected all age groups in the population, school-age children and young adults seemed to be affected most frequently. With the exception of three isolations of A' virus and a few positive serologic tests for A', type B virus was incriminated in all outbreaks throughout the country. Reports from the regional laboratories indicate that these strains of type B virus were more similar to strains isolated since 1945 than to the earlier strains such as the Lee. Influenza C was identified by virus isolation in Illinois and by serologic tests in six cases in Michigan during the past winter.

The strain study center received 20 strains of influenza virus isolated during the past season. They all appeared on preliminary examination to be type B and reasonably closely related to recently isolated B strains. However, they seemed to be less closely related to the Seattle/49 strains than those received in recent years. Strains isolated and examined at the University of Michigan with ferret antisera appeared to be closely related to the Allen (1945) strain but not to the Lee. Likewise, a number of strains isolated in Norfolk, Va., and examined at the National Institutes of Health were similar to the 1210 strain (1950) and the Warner (1945) but not to the Lee. Like observations were made at the Johns Hopkins University and some regional laboratories.

Examination of the National Office of Vital Statistics reports of deaths from influenza and pneumonia in 58 cities in the United States in-

dicates that during the winter season there was no appreciable increase in the mortality rates for these diseases. Only two areas in the country, New England and the East South Central States, showed a slight increase during March. In no area was the increase greater than in 1951.

Reports which are summarized in the two accompanying tables were received from 36 of the 54 participating laboratories. A total of 92 isolations of virus have been reported, 89 of which were type B, and the remaining 3 strains were A'. The majority of these were from cases having onset during the month of Feb-

Table 1. Isolations of influenza virus reported by participating laboratories of the influenza study program in the United States, 1952

1952, month	Date of onset known		Date of testing, onset unknown	
	A'	B	B	C
January-----	2	4	0	0
February-----	1	52	1	0
March-----	0	27	2	0
April-----	0	3	0	14
Total-----	3	86	3	14

Table 2. Positive serologic tests (hemagglutination inhibition or complement fixation) for influenza reported by participating laboratories (civilian and military) of the influenza study program in the United States

1952, month	Date of onset known		Date of testing, onset unknown	
	A, A'	B	A, A'	B
January-----	5	51	0	10
February-----	12	155	13	52
March-----	4	241	3	86
April-----	1	8	0	5
Total-----	22	455	20	153

ruary. The second table shows a total of 650 cases diagnosed by serologic tests (hemagglutination inhibition and complement fixation tests) with 608 tests positive for type B and 42 for A and A'.

Summary

It would appear that while influenza type B has been locally prevalent throughout the United States during the winter months and in some instances has had a high attack rate, there was no significant mortality associated with the disease in 1952.

Ideas

Tenant Nurses

CUYAHOGA COUNTY, OHIO.

Building homes for their families and establishing nurseries for their children has been suggested here as one way to attract married nurses to a hospital in a rural area.

The addition of 260 beds this summer increased the facilities of Sunny Acres Tuberculosis Hospital at Warrensville to a total of 650 beds. The success of Cuyahoga County's tuberculosis program depends on getting enough nurses to staff the hospital.

The plan proposed for Sunny Acres calls for building individual homes to house the families of married nurses on farmland adjacent to the hospital, charging a reasonable rent, and amortizing the cost to the county over a 25-year period. Single nurses also may be attracted to the country life and the individual homes at Sunny Acres. It is estimated that the individual houses would be cheaper per square foot than a dormitory-type nurses' home.

The Cuyahoga County tuberculosis controller, Dr. Joseph B. Stocklen, has presented the idea to the trustees of the hospital and the county building commission who are investigating its possibilities.

Film Saving

LOS ANGELES COUNTY, CALIF.

The preservation of negative X-ray films taken in mass surveys is not a storage or reference service problem in the County of Los Angeles Health Department.

After reading, films are inserted in folded cards which are then metered and mailed either to the persons surveyed or to the physicians of referred patients. Past practice has proved the procedure to be economical and satisfactory.

The cards are of postcard color and quality. For 4- x 5-inch films,

the size is 5½" x 8½" before folding. Standard postcard size, double-fold, is used for 70-millimeter films. At the time of exposure, the cards are stamped with the patient's control number and addressed. On the reverse side of the card, a printed statement informs the recipient that the film is negative and that he is responsible for its safekeeping.

As a further economy, the health department finds the 4- x 5-inch film of increasing usefulness in chest reviews where the large 14- x 17-inch film was formerly considered necessary.

Nonstop Photocopying

DES MOINES, IOWA.

Where a darkroom is available, a satisfactory arrangement for speeding the development process is provided by cutting a hole in the wall of the darkroom and running the conveyor belt of the photocopy machine through the hole so that exposed paper can drop into a box inside the darkroom. See the accompanying sketch.

This device permits continuous operation and rapid development. It is unnecessary to remove the transfer box at any time.

Seminar For Supervisors

NORTHERN VIRGINIA. Health officers and other public administrators are equipping themselves for more effective supervision of personnel by attending an evening seminar for supervisors.

The seminar is sponsored by the cities of Alexandria and Falls

Church and the counties of Fairfax and Arlington. The four Virginia communities are a part of the metropolitan area surrounding Washington, D. C.

The University of Virginia gives six credits to participants. The seminar meets once a week for 3 hours and is supervised by Dr. Roland Eggers, director of the university's department of public administration.

Health officers, city managers, county executive officers, police superintendents, welfare directors, recreation directors, and directors of public works have already attended the course.

Discussion topics in the weekly sessions have included—

The supervisor's responsibility for getting the work done.

Orienting a new employee.

Practicing and reviewing methods of instruction.

Conferences and meetings as instructional devices.

The installation of new methods.

One Tape: One State

NEVADA. The health department has full radio coverage of the State with a single tape recording of its weekly 15-minute health talk.

Several years ago, a Reno radio station agreed to broadcast a 5-minute weekly dialogue prepared by the State department of health. The radio studio provided the narrator. A few months later, it invited the health department to lengthen the script to 15 minutes and readily agreed to make an extra tape recording of each program.

Las Vegas, Elko, and Ely stations joined the broadcast series. The one additional tape is all that is needed, because the four stations are remote from each other, and simultaneous broadcasting is unnecessary. Thus, the health department's message reaches the north, east, south, and west areas of Nevada.

The radio stations speak well of the quality of the programs, which are strictly a home product. Limited personnel and budget need not stymie public health information.

Establishing Housing Standards for the Aged

By JACK MASUR, M.D.

THE PROBLEM of providing housing for older people is by no means a new one. Last summer in Brussels I met an old friend, a Dutch physician and director of an excellent small hospital, who brought this fact forcefully to my attention. During the meeting, we discussed at some length the new and highly important developments in the housing of the able-bodied aging. I noticed that my friend seemed impatient with the discussion and asked him what was wrong. He said, "I'll tell you about it later."

About 2 weeks later, on our way to visit some health officials in Holland, we stopped in the city of Delft. Here he took me down a pleasant street. He stopped before a small door in a neat, red brick wall, opened the door, and stood aside for me to enter. We stepped into a beautiful garden, surrounded by a quadrangle of single-story rooms. Each room seemed to have different furniture, and there were nick-nacks of all sorts about—photographs, pottery, books. My friend explained that these rooms were the homes of elderly women who had brought in their own furniture and other possessions so that they would feel at home. Some of them were out visiting friends, he said. Others were shopping or working a few hours. I expressed a great deal of satisfaction with such an arrangement for the care of able-bodied aged ladies. Then he took me to the corner-

stone and pointed to the date: "Established in 1607."

He said, "Now perhaps you will understand my impatience with the great new thinkers who have arrived at the principle that it is highly desirable to provide older people with the opportunity for some independence of living and some self-reliance. We Dutch thought it was a pretty good idea 350 years ago."

Many of you are now faced with the task of establishing standards of institutional care for the aging, as provided by the recent amendment to the Social Security Act. Congress outlined the problem as follows:

"Tragic instances of failure to maintain adequate standards of care and adequate protection against hazards threatening the health and safety of residents of institutions emphasize the importance of this function of State government. . . . Persons who live in institutions, including nursing and convalescent homes, should be assured a reasonable standard of care and be protected against fire hazards, insanitary conditions and overcrowding."

This amendment will support the efforts of public and private agencies to strengthen institutional care, services, and programs. But our responsibility reaches beyond this immediate requirement of the Social Security Act. We are concerned with housing for all the aged—the able-bodied who live in public and private institutions, the sick in nursing and convalescent homes and in hospitals, and the great majority of our elder citizens who live in private homes.

A beginning has been made in the establishment of standards of care through such organizations as the American Association of Nursing Homes and many State organizations. Most

Dr. Masur, an Assistant Surgeon General, is chief of the Bureau of Medical Services, Public Health Service. This paper is a condensation of remarks made on July 26 before the fifth Annual Conference on Aging at the University of Michigan, Ann Arbor. (See page 1197.)

States have limited standards for the licensure of homes for the aged, though many such standards hardly deserve the name.

It has been said that much more information is needed in the field of geriatrics before standards can be established. Obviously, we need to know more about chronic diseases, the physiological process of aging, the effect of diet on longevity and on glandular activity, and the work capacity of older persons. We must learn more about the psychology of aging and more about what older people want. But there is already a considerable body of knowledge, and we dare not delay constructive action indefinitely on the pretext that we need additional information, data, and guidance.

From Ideas to Reality

The establishment and maintenance of adequate standards in a field as complex as this is an enormous task. No matter how great the need, no matter how fully the importance of such standards are understood, the task of transposing them from thought into reality is enormous. Still, it has been done in other fields; for example, in hospital care.

In 1940, when the Hospital Survey and Construction program was being seriously discussed by the hospital and medical professions and the Public Health Service, the same problem arose. There was no uniform pattern of standards for hospitals, and there was grave doubt as to the possibility of establishing such standards on a systematic basis. Many felt that such action would be an invasion of the rights of the States, local communities, and private interests. Nevertheless, a few far-sighted hospital people insisted that standards could be established.

These people called upon leading physicians, hospital administrators, architects, and other interested persons to assist in drawing up hospital care and construction standards. In 1946, these standards, with innumerable variations to make them adaptable to all State and local needs, were made the minimum requirements of the National Hospital Survey and Construction Act. Communities applying to their States for funds under this program were required to meet

these standards. In a short time, States and communities throughout the country had accepted and carried these concepts forward to practical application.

Major Steps

With certain variations, the three major steps taken in the development of standards for hospital construction and care can be used to develop standards of housing for the aged.

First, you who are directly engaged in the care of the aged can select what you believe to be the minimum standards. Your knowledge and your experience are invaluable. Though you may feel that your information is incomplete and inadequate, you are the only experts in the field.

There are several sets of standards available which can serve as guides. The Welfare Council of New York City has issued a pamphlet called "Suggested Standards for Homes for the Aged." The Methodist and the Lutheran Churches have set up standards for the management of their own homes and hospitals. The National Committee on Aging is now working on a set of standards and a subcommittee of the Committee on the Hygiene of Housing of the American Public Health Association is developing a special report on housing for the aged. This latter committee has also established a guide, "The Basic Principles of Healthful Housing," which can serve as an excellent framework for developing standards.

Practically every health department in the country has had experience with the development and administration of standards programs for hospitals and related institutions. Obviously, the State health department can be a key official agency in the formation of these standards.

The second step is really a check and balance on the first. When a set of standards has been drawn up, a group representing all interests concerned with problems of the aging should be called together. This group should include physicians, psychiatrists, and welfare workers; representatives from the health department, fire department, building inspector's office, and any other branch of the municipal government concerned with either shelter or care of the

age; and representatives of industrial, labor, religious, civil, and other local organizations. Do not, under any circumstances, limit the membership of such a committee to a single group of health officials, welfare authorities, or architects. It is invaluable to obtain the support of all who are concerned with the aging.

This step can lend prestige to the program. It can contribute to the workability of the standards, and it can establish a foundation of professional and official support that is essential to their acceptance.

The third step is to give the standards legal status in order to prevent abuse by imprincipled persons. Here, again, the backing of all the above-mentioned groups must be obtained. Ultimately the translation of the standard from paper to reality depends upon widespread public understanding and active support.

A Broad Approach

I would like to emphasize the importance of a broad approach to the problem of housing for our older citizens. Housing is so complex and is woven in so many ways into our whole pattern of living that significant progress in providing housing for a major segment of older persons can be achieved only as basic progress is made in providing decent housing for the Nation as a whole.

Substantial reduction in the cost of housing for aged persons will be achieved only in the measure that we reduce the cost of housing for all people. Extensive revisions and improvements are needed in designs, materials, construction methods, financing, and even perhaps in our concept of housing if real progress is to be made in cost reduction.

Another basic consideration is the important financial and therapeutic relationship of housing to medical care and hospitalization. Although this relationship is important for the general public, it is particularly significant for the aged, infirm, and chronically ill.

Recent pilot studies in home care for prolonged illness indicate that patients who do not need hospitalization but require more care than just out-patient clinical services are more comfortable and get well more quickly in their homes than in a hospital. The economic dif-

ferences are even more striking. Today, hospital costs are about \$20,000 per bed. If the average cost of hospitalization per patient-day and the average cost of home care per patient-day are compared, the cost of care for a patient at home is one-fifth to one-third the cost of hospitalization.

We are particularly interested in good housing for all our older people because we realize that medical care facilities are seriously overcrowded and must be saved for those patients who need hospitalization. Furthermore, the lower cost of home care will allow more funds to be used for better housing, education, and food. Unfortunately, there are several factors limiting the use of home care, particularly for the low-income persons who most need its financial advantages.

According to the 1950 housing census, there are at least 16,000,000 dwellings that have one or more basic health deficiencies. For example, more than 12,000,000 urban and rural dwellings have no bathtub or shower, and nearly 8,000,000 urban and rural dwellings have no running water inside the structure. Surprising as it may seem, only about 40 percent of these health deficiencies occur in rural farm areas. The millions of American citizens living in such housing know that it would not be adequate, let alone suitable, for use in home care of a patient. Hospital administrators are all too familiar with the need to postpone the discharge of a large number of patients because they would have to return to housing totally unsuitable as a convalescent environment.

What is to be done to bring about conformity with even the present established standards of housing for the population as a whole--the simple basic requirements necessary for elementary decency, cleanliness, and health?

Rehabilitation of Substandard Housing

An attack on housing conditions is being made through new construction, redevelopment, public housing, and special institutional housing. But the opportunities for improving existing substandard housing by the application of health regulations have been given far too little attention. Certainly a tremendous volume of new housing is needed. But the housing problem can also be attacked by

prevention of accelerated rates of deterioration of dwellings and their environment and by rehabilitation of existing substandard housing that has a sound frame and foundation. In short, prevention, rehabilitation, and production are all necessary to improve housing conditions. As general housing conditions are improved, progress will be made in the provision of decent housing for aged people as well.

It has been demonstrated in more than a score of communities in the last few years that rehabilitation of substandard dwellings is practical and productive of immediate results. It is no panacea; it is not the end; but it is a necessary and salutary beginning. After this fundamental approach has been made, attention can be given to other needs. We can begin to consider standards for institutions and for care for the aged.

Public Interest and Support

Of prime importance before effective standards can be established is recognition of the fact that the public must be interested in the problems of the aging. The formulation of public policy in this regard is of the essence.

During the past few years there have been dozens of magazine articles and books on the aging, even a play. Today there is far more interest than there was at the end of World War II. But this appearance of interest does not constitute the backing necessary to transpose

a set of professional standards into a practical and acceptable way of life. Specific action must be taken.

First, I suggest that you look to your State health and welfare departments as the official agencies to provide leadership in establishing and maintaining standards; second, crystallize your ideas about standards of facilities and care, and set them down in detail; third, seek out all interested persons and groups concerned with the problems of aging and enlist their aid.

Perhaps public understanding and support can best be achieved by forming a local organization which can serve as a rallying point for all who are interested in the problems of the aging. When such organizations are formed in many communities, in the States, and in the Nation, they will raise a voice that must be heard. This voice will provide the support necessary to give legal status to the establishment and maintenance of the standards, which can then serve as the springboard for national action.

To interest the public in making a reality of a standard of decent shelter we must mean business; we must close our ears to the counsel of despair and disillusion. Throughout history there have always been timid souls who would not venture to walk to the rise of the next hill. There have been those whose fears of disaster paralyzed their will to act. But the majority force in society today is the force that has a will to grow and to live.

Rehabilitation Reduces Assistance Cases

During the past fiscal year, 63,632 disabled civilians were rehabilitated, and more than 12,000 of these were public assistance recipients, the Office of Vocational Rehabilitation recently reported. The successful employment of one out of five rehabilitated disabled persons meant an aggregate earning of \$22½ million for this group which the year before received about \$8½ million in assistance.

This percentage of rehabilitated persons removed from public assistance case loads was the highest ever recorded; 12 percent was the figure for the preceding year. Taken from the case load were 5,200 disabled parents in families who had received aid to dependent children; 1,200 who had received aid to the blind; 800 who had received aid to the permanently and totally disabled; 400 who had received old-age assistance; 4,000 who had received general assistance, and about 400 who had received unspecified aid.

Housing and Health Facilities

For Our Senior Citizens

LIVING arrangements for older people who are well, sheltered care and medical supervision for those who are ill and feeble, and custodial care for those whose health is uncertain, must be tailored to meet individual needs and wants. This threefold emphasis on personal desires, and on recognition of individual differences among senior citizens in our population, keynoted the 3-day conference on "Housing the Aging" held July 24-26, 1952, at the University of Michigan, Ann Arbor.

We Grow Older

The significance of shelter for the aging and its relationship to health was underscored at the conference by realization that, although the decrease in mortality at the middle and upper ages has not been conspicuous within the last half century, it has been considerable at the younger ages, resulting in a material increase in the number of people attaining maturity and old age. This condition is likely to improve and continue, raising the proportion of older persons in our population.

Population statistics for men and women present contrasts which must be considered in meeting the problems of older people, particularly with respect to their housing and their maintenance. In 1950, in the 65 and over age group, women exceeded men by over one-half million. For every 100 women there were fewer than 90 men. Perhaps more important is that there is a higher mortality among males and that women usually marry about 3 years earlier than do men. Widowhood is a characteristic marital condition of older women. In 1950, more than half the women of 65 and over were widows, but only about one-fourth of the men were widowers.

Where Older People Live

Of the 12.3 million persons aged 65 plus in 1950, and representing 8.1 percent of the total population, about 94 percent (or 11.6 million) lived in households. Only 6 percent, about 700,000, lived in rooming houses, institutions, hotels, and homes of various types. Of those 65 and over living in households, the largest group, comprising 5.4 million individuals, were married couples living in their own households. The next largest group of individuals lived with relatives and numbered 3.9 million.

According to a special sample study by the Census Bureau and the Housing and Home Finance Agency, about two-thirds of our older families lived in nonfarm dwellings in 1950 which had modern conveniences. The other third lived in substandard housing ranging, in condition, from dilapidated to without running water or private toilet. One important clue may be found in the Census Bureau's estimates of family income for 1950; 51 percent of all families in which the family head was over 65 had incomes of less than \$2,000 a year, and more than 30 percent of them had incomes of less than \$1,000. In this group, those who lived alone or with nonrelatives fared even worse—over 89 percent had annual incomes less than \$2,000, and more than three-fourths had incomes less than \$1,000. These resources, unless coupled with savings or other income, cannot rent or buy homes.

Older people, like the rest of the population, have concentrated in the urban areas, it was brought out in the discussions. Around 1945, about 60 percent of the total population as well as the aged fraction of the population were classified as urban dwellers. Since that time, the elder group, congregating in city centers, has increased faster than the general popula-

The 5th Annual Conference on Aging was held at the University of Michigan in July. Represented were governmental agencies, real estate and housing interests, both public and private, university and professional groups, architects and builders, nursing and convalescent home organizations, and labor unions and hospital authorities. Over 500 attended the sessions, which were sponsored by the university in collaboration with the Committee on Aging and Geriatrics of the Federal Security Agency, the Federal Housing and Home Finance Agency, and the Michigan State Medical Society.

The conference provided opportunity for an integrated review of knowledge about the housing of healthy, disabled, and sick older people. A full accounting of the discussions will be published as proceedings in the near future.

tion. They are found predominantly in the large industrial States. New York, Pennsylvania, California, Ohio, and Illinois claim about 40 percent of the aged population.

Neighborhood Demands and Planning

The conferees saw the need for development of new community understanding to offset fears concerning the burden of old age and misconceptions concerning the wants and requirements of older individuals. It was clear that older people strongly prefer to remain independent, to earn their own way as long as possible, to remain active participants in their communities, and to make a contribution in keeping with their experience and maturity. In short, they want to live their own lives.

As one participant declared, children have the right to think and act as they wish, and we have the right to think and act as we wish.

Whether they prefer individual homes or group living, older people want to be near public transportation or, preferably, within walking distance of community facilities such as stores, churches, libraries, and movies. They want to be able to carry out the same kind of activities as others: shopping, visiting relatives, relaxing, and working when possible. They do not wish to be segregated in planned projects, and have

At this time, *Public Health Reports* presents on pages 1192-95 Dr. Masur's paper on the establishment of housing standards, and the accompanying report of Irving Ladimer which summarizes the health features of the conference. Mr. Ladimer, with the research planning branch of the National Institutes of Health, Public Health Service, participated in the conference.

Housing for the aging is a field of challenges and unknowns, calling for incisive thinking. Even where facts are agreed upon, different emphases modify their use and implications. Dr. Masur's paper and Mr. Ladimer's report reflect the variety of interests and opinion which so often characterizes discussions of health and medical services for our older citizens.

no great desire to move to new communities. Although there is a sizable group that looks forward, upon retirement, to moving back to the farm or to the sunshine States, most older people finally realize that they want to continue their familiar activities.

Conferees admitted that there were many individuals who did find it possible to carry out their youthful dreams of a retirement devoted to hobbies, to travel, or to new ventures, but that most of them continued lifetime pursuits if possible. Older individuals want to be near medical facilities and want doctors, nurses, and family confidants available in their later years. This yearning is particularly important when health is failing and problems of remaining healthy become paramount. The ability to get up and go cannot be taken for granted.

Consequently, neighborhood planning plays an important part in meeting the needs and desires of older people. Although there have been a number of very highly successful group living arrangements established for older people, the conference recognized the basic objective of keeping a place in the main stream of life for our older citizens.

The conference suggested that zoning ordinances and related land use control should be examined critically. Suitable housing for the

physical and emotional requirements of the older ages should be widely distributed throughout the community. Consideration should be given to population density, need for privacy, parking, and community centers. The development of neighborhoods which provide a variety of conveniences—from small neighborhood stores to large shopping centers—requires large-scale planning rather than lot-by-lot consideration.

Private enterprise representatives asserted that the home-building industry can achieve results at the instigation and promotion of community leaders. There was also strong feeling, on their part, that leadership for such improvement would have to come from informed consumer action—possibly through public agency cooperation and control.

Design and Sheltered Care

In designing housing for older people it was recognized that there are certain conveniences and safety measures which are important. Today, builders tend to consider the young family and to overlook the needs of later years.

However, it was the consensus of the conference that homes suitable for the young family were essentially adequate in construction, in design, and in durability for older people. True, certain additions or improvements are available and should be introduced to meet individual physical and psychological problems and declines in basic abilities in much the same way as changes are made when children are introduced into a home. But housing experts pointed out that relatively few older people require significantly different or special features in homes, apartments, or institutions. Basementless homes and single-story houses were suggested as features which would be preferred by many families but which would be particularly adapted to the shrinking capacities of the senior group. Here again it was affirmed that aged people are individuals—human beings—and not a monolithic group.

Major issues at the conference of special importance to public health officials related to requirements of our elders for sheltered care and for medical supervision. Conference discussions centered on the need for appropriate participation by health workers in city planning, in

home design, and in building. Health workers must gain more insight into the factors relating to population change, education, family life, creative and recreational activities, religious programs and services, income and resources, and community organization. Healthful living and creative contribution depend on all these.

The doctor, the nurse, and the health worker, whatever his specialty, must be observant, sympathetic, and alert in recognizing these varied elements and the opportunities to cooperate with other professions and disciplines. The health officer, potentially, if not always in fact, is a community leader when it comes to health education and provision of medical care. The special skills and experiences which medicine and public health training have to offer can probably best be evidenced in the provision and management of general and special hospitals and neighborhood clinics and in the support of the large variety of nursing homes, convalescent homes, and old age institutions.

Quite early in the discussion of supervised care for older people, it was concluded that there were three distinct but overlapping groups of older people: the able bodied; the infirm; and the disabled—counting those acutely ill and those suffering prolonged ailment or other conditions requiring medical or special care.

It was agreed that mostly it was unnecessary to provide institutional care and complete medical supervision for older people as such. Even for the unwell with long-term stabilized infirmity or for older people with periods of good health matched by strain or fatigue, there may be question about utilizing expensive hospital beds and providing full medical treatment. Many such persons probably need, more than anything else, just assurance, sympathetic understanding, and general surveillance of their health, with, of course, suitable treatment available for acute conditions.

There was disagreement among the conferees on the advantages of geriatric units or of special facilities for infirm older patients which would be physically attached to and integrated with general hospitals. Is it more feasible and economical perhaps to establish in separate institutions patients who are well as often as they are sick?

No disagreement existed, however, concerning the need for a close relationship between the general hospital and such centers, for staffing them with well-trained doctors, nurses, and medical aides, and for equipping them with general and emergency treatment facilities. It was pointed out that in a hospital an older person may face the possibility of realizing a surrender of independence and responsibility which is accompanied by a loss of sense of security. He sometimes associates illness with aging.

In emphasizing the desirability of closely relating the hospital and geriatric unit for infirm older people, these advantages of such an arrangement were noted: It allows approved medical supervision. It provides better records through integration with the hospital system. It offers access to hospital facilities, especially for diagnosis. It permits lower capital outlay for geriatric structures and lowers over-all unit costs. And, finally, it lessens the problem of moving the older person from one unit to another.

At the same time, older people who are confined to separately constituted public or private rest homes or to custodial institutions have a constant fear of falling ill, unless they have confidence that the organization can quickly provide necessary medical care.

Older people in good health usually do not need institutional care. Even without family or resources, it is possible for an older person to set up a new home with similar friends in a regular community or through congregate living arrangements, if he has been stimulated and aided in making the new arrangements. But, the conferees noted, there is a fallacy in not recognizing that people do become feeble and infirm as they grow old so that some type of medical supervision for older folks is essential, whether they live independently or live in a home that is essentially a boardinghouse or an old age institution.

Ideally, the services of both a general hospital and of a specialized institution should be provided for older people, with the closest interplay of staff and exchange of services. Older individuals may then proceed at their own rate in keeping with their abilities and their interests. They have the assurance that a helping hand is ready when they falter.

As one speaker summarized: "Although the problems of the aged and those of chronic disease are not synonymous, they are so closely interrelated that they cannot be studied in separate parcels."

Nursing and Convalescent Homes

Nursing and convalescent homes and other institutions for the aged, needy, or infirm may be variously classified according to the purpose of study or function. For example, they can be grouped by ownership, that is, public or private; and by size, structure, or nature of service provided. The most useful classification probably is the last, nature of service.

Statistics on the number of such institutions are not yet validated because of State differences in definition, licensure requirements, and regulation. A listing of institutions in 1948 and 1949 prepared for the 1950 census indicates that there were then about 5,200 old age homes. About a fourth of these were public; another fourth were private and nonprofit; and half were proprietary establishments. In that list, there were also 6,400 nursing and convalescent homes, mostly private commercial ventures.

Many conference participants strongly assented to the proposal that the quality of service to be available at nursing homes should, at most levels, be of the same caliber as that provided in hospitals. Financial studies covering a wide range of nursing, convalescent, and other institutions which provide medical care indicated that costs of care in such institutions came to about two-thirds the cost of general hospital care.

One participant who had made a survey of the several types and categories of homes caring for old people and other individuals not requiring hospitalizing urged the conference to promote uniformity of service standards for all places accepting responsibility for sheltering persons who require nursing assistance or medical supervision. The speaker said that a nursing home is a substitute for the patient's own home—not a diagnostic or specialized treatment facility. Hospitals are available for diagnosis and special treatment and should be integrated within the pattern of geriatric care. It was recognized that, traditionally, professionals in

the hospital field and in the area of chronic illness recommend special facilities and different standards for the major categories of facilities. If the service classifications in the homes were well accepted and were followed, and if older people were properly diagnosed, this uniformity could be achieved. Since there is considerable lack of uniformity as to designation, size, and legal status, it was felt that at least all facilities represented as providing medical care should be held to a basic standard.

All participants strongly emphasized that both the general hospital and the nursing home, or the home for the aged—under any name—must go beyond custodianship to engage actively in rehabilitation programs. As put by one speaker, the operation must constitute "reverse social service," with strong accent on returning patients to their homes and communities rather than placing patients in institutions. Some participants went so far as to declare that there was no such thing as chronic illness if it were understood within the meaning of a generation ago as hopelessly disabled or incurable—that there was only acute, subacute and inactive disease, always allowing the possibility of cure, restoration, and rehabilitation.

Problems and Standards

Nursing and convalescent homes, it was constantly noted, have various names. They are strictly regulated in some States and are not even registered in others. Some are subject to State legislation and local ordinance. They provide a variety of services, in physical structures of all types. It is estimated that nursing, convalescent, and boarding homes of various types care for well over 100,000 individuals annually, and constitute an important and indispensable adjunct to the Nation's hospital beds. In 16 States for which data over a period of years were collected, there would appear to have been in 1950 an average of 1.05 nursing beds per 1,000 population, or about a third of the non-Federal general hospital beds in those States.

Those homes which assume responsibility for patient care and treatment under suitable medical standards for cure and rehabilitation should be able to provide the physician and his patient with some of the same services a general hospital

provides with the exception of specialized diagnostic, laboratory, and surgical and technical service. Such homes could profitably be used as adjuncts to general hospitals in the best sense with special concern for the relatively stabilized infirm and for those wavering between good and ill health.

It was the plea of the nursing and convalescent home operators attending the conference that the medical profession should give more attention and recognition to these facilities and should take responsibility for educating owners and operators concerning their needs in order to elevate standards. But, they added, if all superior features of design, staff, and equipment were incorporated, the attractive lower rates which such homes now offer might no longer be possible. At present, estimates indicate that, for the best-staffed homes providing care of good quality, operating expenses are from two-thirds to three-fourths that of general hospitals in the same area, and their daily rates are commensurately lower.

Usually, nursing and convalescent homes have been established in structures and large old mansions which have been equipped for bed and ambulatory care. These homes do not usually incorporate desirable design nor are they always easily accessible or close to medical centers.

Nursing home operators admitted that advances were desirable, but that they could be achieved only by increasing rates. There is, in many States, the essential division of responsibilities between regulation and standard setting by one State agency (the health department, for instance) and payment for care of public assistance and State ward cases by another agency (such as the welfare department). The first seeks to improve service and thereby raises operating expenses whereas the latter naturally seeks to get maximum service at the customarily low rates determined by the legislature. The conference recognized that the improvements sought could not reasonably be provided unless public payments were increased.

In one of the closing conference addresses on the subject of establishment and maintenance of standards, the speaker strongly advocated immediate action on the basis of available knowledge. Three steps were outlined:

Agree on minimum standards.

Get community support and aid from groups representing all interests.

Then get legal status for the standards approved.

Many suggestions were offered for improvement of design, architecture, engineering, and management of the nursing or convalescent home, but no standard pattern was generally accepted by the conferees.

It was agreed that any plan should respond to the program or objective of the institution. Popular and widely advertised features such as treatment rooms, equipment, day rooms, and recreational areas, individual bathtubs and the like, while helpful, are not always essential for the provision of high-quality care. More important are factors of leadership, motivation, and adequate staff training. Remodeled old residences can be quite satisfactory and of great assistance in providing sheltered care facilities for the Nation when they are properly licensed, inspected, and maintained.

Nursing home operators, it was noted, have made substantial contributions to the widely ignored problem of care for the aged infirm population. They should now concentrate on developing standards; on cooperating in research on physical design and structure; and on promoting effective criteria for licensing, inspection, and control. They should concentrate on working out spheres of activity and functioning with hospitals and prepayment plans. They were urged to get positive public recognition of their role in medical care.

Financing

One of the most significant and acute problems facing older people is that of adequate financing of medical care. Maintenance of older people in general hospitals for long periods of chronic illness which does not require hospital care constitutes a great and questionable economic burden. It is not, however, sensible or justifiable to exclude from general hospitals older people requiring hospital care, unless other acceptable high standard facilities are available.

Some hospitals, notably Montefiore Hospital in New York and Michael Reese in Chicago,

have successfully experimented with home care programs. Here chronically ill persons, young as well as old, are supervised in their own or in convalescent homes or in boarding houses. Such a program involves the extension of the medical, nursing, and staff services from the hospital and requires greater reliance upon such community facilities as visiting nurse care and recreational and educational resources. It has the great advantage, of course, of enabling the patient to stay in his own environment and of lessening his adjustment problems while it frees hospital beds for acute cases. For the hospital, there is a much lower cost for patient care. For the economy generally, home care is to be preferred. Good family housing can be provided for as low as \$3,000 per person, but hospital beds may each cost about \$20,000 a year to maintain. The average cost of home care per patient is between a third and a fifth of the cost of his hospitalization. Even where hospitalization is undertaken initially, every effort at rehabilitation and early homecoming should be made.

Such home care arrangements cannot, however, be extensively established or promoted unless the general hospital is willing to accept its role as an operational base and unless the community and family are willing and able to assume appropriate responsibility. In the individual home, such responsibility at minimum requires healthful quarters. Certainly, it would not be suitable to refer patients home for care to any of the 16 million dwellings in the United States that have one or more health defects, as, no bathtub or shower or no inside running water. This program underscores the significant relationship between hospital or sheltered care and family housing. The one cannot depend on the other to prevent illness or to restore health unless housing conditions generally are vastly improved. Consequently, additional ways to reduce the general cost of care must be sought.

Community Attitude

A physician who is now successfully conducting a joint hospital-community service on behalf of the aged declared that housing needs of older people requiring sheltered care and medical supervision can best be met when it is realized that:

1. Well-off elders can generally care for themselves in individual or congregational households and perform normally when given understanding and sympathetic assistance:

2. Failure to provide in advance for the problem of growing old results in economic, physical, social, and emotional tragedy among the elderly.

Above all, he added, in prescribing for an older person, as for any other, regard the individual as a whole and consider not only physical care but social and emotional rehabilitation. The money cost of preventive service for the older population will in the long run be far less than the cost of neglect, he concluded.

Prepayment Plans

It was proposed that medical prepayment plans be adjusted to include aged persons. These people face the same problems as the rest of the population in paying for medical care, but their problems are much more acute than that of the average person. Their incomes are low. They need more than the average amount of medical service, over longer periods. As a consequence, they have generally been considered poor risks and have less opportunity for enrolling in voluntary prepayment or insurance programs. Most group plans will continue the insurance rights of persons over 65, but most will not accept them on an individual basis after retirement or after age 65 or 70. At the heart of this problem is the fact that prepayment plans are relatively new so that older persons have had no chance to enroll and many who did have found it difficult to keep up the payments.

For the one-fifth of all men and women over 65 now receiving old-age assistance from the Federal and State governments, there has been some amelioration of the problem, conferees noted. Public responsibility for care has been enhanced by the 1950 amendments to the Social Security Act permitting Federal matching of payments for direct payment to institutions and others who provide certain types of medical services. Excluded are institutions for medical

and tuberculous patients—an omission which should encourage the financing of these institutions through health channels rather than through public assistance channels, it was suggested.

Important contributions to solution of the problem, the conference noted, can be looked for from the development of pooled-fund arrangements, increased cooperation between health and welfare departments, and from the medical and hospital professions working together with governmental agencies.

The development of adequate facilities is another step which, it was felt, might be taken immediately to provide medical care for older people. An example in the hospital field was cited. Under the impetus of the Hospital Survey and Construction (Hill-Burton) Program operated by the Public Health Service, volunteer groups, local and State governments, and communities have united in the planning and building of general hospitals. Attention might be given to the requirements of older people by studying the applicable features of the Hill-Burton program and related programs.

Finally, conference discussions emphasized one must not lose sight of—but rather point up—preventive measures. Efforts should be redoubled to keep the elderly who are well out of institutions and thereby save institutional resources for the truly sick and disabled. The individual patient, the family, the community, and all who are concerned with the growing problem of the aged must unite to keep as many of our older people as vigorous and productive as possible.

For the aged and others who must receive medical care it is important to place the right patient in the right bed at the right time. It was reiterated that the expansion of adequate family housing could probably do more to keep the older group out of institutions, particularly boarding and convalescent homes. Failure to utilize appropriate resources represents a waste of money and a public burden.

—IRVING LAMMER

Tuberculosis Control in Connecticut

These nine briefs, taken from discussions on June 18, 1952, at the tuberculosis session of the eighteenth New England Health Institute, Storrs, Conn., give an interrelated picture of a State tuberculosis program.

The Organization

The Connecticut State Tuberculosis Commission in Hartford is the official State organization for tuberculosis control. It was first organized in 1909 for the purpose of providing and managing State tuberculosis sanatoriums. Its present case-finding program of mass radiography, consultation services, education, and rehabilitation was set up in 1939. The five commission members serve without salary for 6 years. The director acts as administrative agent and coordinator. The commission meets for an all-day session approximately once every 10 days.

The tuberculosis commission is in an unusual position to develop a coordinated program with continuity in policy. In Connecticut's 169 distinct communities, tuberculosis control activities are conducted with the cooperation of each local health officer, who is kept fully informed of all State level activities in his community. Almost any community can be reached from Hartford in a matter of 3 hours or less. Connecticut, an essentially industrial State with a population of 2 million, is divided into four sanatorium districts with a State sanatorium for adults in each area.

The 1951 provisional death rate in Connecti-

By Paul S. Phelps, M.D., director, Connecticut State Tuberculosis Commission.

cut for tuberculosis was 14.1, or less than half of the 1940 rate. It has been estimated, however, that there are now approximately 9,000 unknown cases of tuberculosis in Connecticut, of which about one-third are active cases.

Interrelationship

New cases of tuberculosis are reportable, as are deaths, to the Connecticut State Department of Health. They are referred to the commission for incorporation into the State case register, which is supervised by a research statistician. The commission has cooperative working relationships with the rehabilitation division of the State board of education, the Commission on Chronic Alcoholism, and the Connecticut Tuberculosis Association and its affiliated organizations, as well as many other agencies. Several local health departments have their own well-organized control programs with which the State cooperates to the fullest extent. An excellent State laboratory for sputum and body fluid examinations is maintained by the State health department.

Of the 128 visiting nurse associations in Connecticut, 104 are independent organizations. The commission has assigned one of its four public health nursing consultants to each sanatorium district. They use the State case register and work with clinic and survey physicians, sanatorium staffs and patients, and local public health nurses. The coordinator of nursing education in the State Tuberculosis Commission has set up a program of student nurse affiliation with the teaching hospitals of the State.

Connecticut has a potential total sanatorium capacity of 1,515 beds (1,570 beds in State sanatoriums), a ratio of 5.9 beds per death. There are about 175—all men—on the waiting list for sanatorium admission. The ratio of men to women applicants is about 2 to 1. Some of the sanatorium beds are now closed because of lack of personnel and because of insufficient housing for personnel or because renovations are needed. It is expected that most of these conditions will be eliminated in the near future. Funds have already been provided for additional housing, and renovations are already under way. A recent reclassification of State employees may well provide for the lack of personnel, particularly among nurses.

There is still a means test in Connecticut with a minimum charge required by law of \$4 a week although patients are expected to pay as much of the \$70 weekly cost of care as they can afford. Strenuous efforts are being made to eliminate the means test. The town or State must assume financial responsibility for those patients without funds.

In 1951, approximately 201,779 apparently well adults were X-rayed throughout the State; 12,900 patients were admitted to State sanatoriums; 15,246 nursing visits were made by local public health nurses; and 23,814 visits were made to the various consultation services.

The Mass X-ray Survey

PHR The primary purpose of mass radiography is to discover new cases of pulmonary tuberculosis. Its side products are important, too. Most valuable among these is the discovery of nontuberculous chest disease such as abscess and

By Alan L. Hart, M.D., M.P.H., senior tuberculosis control physician, Connecticut State Tuberculosis Commission.

bronchiectasis, chest tumors, and heart disease associated with changes in the size or shape of the heart shadow.

Beginning in 1944, the State Tuberculosis Commission has conducted mass X-ray surveys systematically and on a voluntary basis in communities, in industries, and in institutions. Approximately 80,000 people are X-rayed each year.

Survey Procedure

When a survey is planned, a site is selected for the X-ray unit, and the electrical current there is checked. Two technicians operate a unit at the rate of 50 people an hour throughout a working day. All screening examinations consist of 4" x 5" stereoscopic films.

Seventy-millimeter films were abandoned some years ago in Connecticut. We found, on reviewing 25,000 survey films selected at random, that the percentage of significant chest lesions missed on 70-mm. films was four times the percentage missed on stereoscopic 4" x 5" films.

Film Reports

Films are brought from a mobile survey unit to a central darkroom for careful and uniform processing to give films of good quality and density. All survey films are read by physicians with extensive experience and training in interpreting chest films and in the clinical diagnosis and treatment of tuberculosis. Every film with any significant deviation from normal is set aside for more careful study. During this study, the master files and the State register of known tuberculosis cases are searched for information about anyone whose film suggests possible chest disease. Whenever such information is found, it is incorporated in the report of the current survey film. If previous films are found, interpretations of these are also included in an effort to make the report more useful.

The physician named at time of survey by the person X-rayed receives a report on every positive film. The report indicates possible heart disease and nontuberculous chest disease as well as suspected pulmonary tuberculosis. The report form includes a chest diagram on

which the locations of lesions can be marked. Space for noting further study suggestions is also provided.

Survey Findings

In 1944, the percentage of tuberculosis picked up was approximately 1.5, rising to 1.67 by 1946. It is now about 0.5. At first, the increasing volume of survey work was sufficient to offset the percentage decline, and the number of cases discovered each year continued to rise until 1950, but there has since been a fall in the total number of cases discovered.

From carefully controlled studies of surveys in selected industries and selected stable communities, we know that the percentage of new cases falls off very rapidly when surveys are repeated. From this, we conclude that 4 to 5 years should elapse between surveys in the same place, unless the turnover of employees or increase in population has been great. It now seems unnecessary for purposes of tuberculosis control to make annual surveys in the same population groups.

Another observation is that our surveys pick up most tuberculosis in middle-aged and elderly adults—in the forties and fifties among women, and in the fifties and sixties among men.

Approximately 72 percent of the cases of pulmonary tuberculosis picked up in mass surveys are minimal; less than 20 percent are moderately advanced; and less than 5 percent are far advanced. In a minimal case, the patient seldom has any symptoms of which he is aware, and he is naturally reluctant to believe his condition warrants medical treatment or hospitalization. Also, many physicians are reluctant to believe that people can have pulmonary tuberculosis when they show no clinical symptoms and there is nothing to direct attention to their lungs except a shadow on a chest film. The tendency is to reassure the patient that the lesions are old and inactive, but the tragedy comes later when the same patient is found to have moderately or far advanced disease.

The precise value of mass radiography in tuberculosis control will be determined by future events. With good follow-up and clinical evaluation, it can help to build a more effective control program.

Consultation Services

The field consultation services of the State Tuberculosis Commission were established to augment the existing clinical facilities available at the out-patient departments of the sanatoriums and at locally operated city clinics.

Presently, there are in Connecticut 13 field consultation services, 5 sanatorium out-patient departments operating directly under the tuberculosis commission, and 5 city clinics and 1 sanatorium out-patient department cooperating with it.

Plans and details of operation are discussed in advance with the local health authorities and physicians. Space for a waiting room, nurses' room, dressing room, X-ray room, and examining room is made available in the local health department, in the hospital, visiting nurses' quarters, or elsewhere. Equipment is furnished by the State, and the permanent equipment is installed and tested prior to the first session at the field clinic. All film processing is done at the central office of the commission in Hartford.

Consultation Schedule

After estimating the number of clinical sessions per month, the tuberculosis commission notifies every physician and nursing agency in the area. A schedule of proposed clinic sessions showing date, time, and place, and a supply of "request for examination" forms are enclosed with each letter. No charges are made for services, which are limited to the diagnosis and follow-up of the known case of tuberculosis, the suspect of chest pathology, and the contact. Patients are accepted by physician referral only and are seen on an appointment basis. Examination results are reported to the family physician, and the patient is instructed to consult with him.

As "request for examination" forms are re-

By R. C. Edson, M.D., chief, tuberculosis control, Connecticut State Tuberculosis Commission.

symptoms of tuberculosis, to his family, and to the physician who must decide whether he should remain at home or receive sanatorium care. The cost to the State is small when we consider that otherwise undiagnosed cases are found by laboratory tests, thereby removing the infectious person from general contact with persons who might become infected, and thus preventing an unknown number of possible new cases as well as the further damage that could result to the person himself.

40 Years of Tests

The examination of sputum for tuberculosis was one of the three or four tests for detecting communicable diseases which were undertaken when the bureau of laboratories was first established in 1905 on the campus of Wesleyan University in Middletown. At that time, the only test made was a stained smear on untreated sputum which was examined microscopically. Laboratory techniques were improved over the next 40 years, and today's findings are infinitely more reliable. Inoculations of animals with materials suspected of containing tubercle bacilli were started in 1925, but these tests were few. Routine culturing of sputum for tubercle bacilli was begun in 1941.

Laboratory examinations for tuberculosis rose undramatically from small beginnings in 1905 to almost 2,500 in 1942, but reached a surprising high of 14,000 in 1951. Of all laboratory examinations made for the diagnosis of all communicable diseases, those for tuberculosis rose from 3.6 percent in 1942 to 12.7 percent in 1951. By 1951, the number of tuberculosis examinations had increased 500 percent over those given in 1942, even though the number of all yearly examinations now given in the bureau still approximates the 1942 figure.

Laboratory Tests

Currently, laboratory tests on materials from tuberculosis suspects comprise:

1. Microscopic examinations of sputum which has been treated to concentrate the causative agent in the portion to be examined.
2. Cultures of sputum and other body fluids to grow the living bacillus *Mycobacterium tuberculosis*.
3. Animal inoculation tests on body fluids, and on sputum on request, and occasional animal inoculations to test the virulence of nontypical cultures.

The specimens are concentrated with sodium hydroxide 4-percent aqueous solution, shaken in a Babcock shaker, and centrifuged in an angle centrifuge. The smears are stained with Ziehl-Neelsen acid-fast stain and are examined and reported promptly after arrival at the laboratory. The concentrates are cultured at the time of making the smears. Most positive cultures appear after approximately 3 weeks and are reported as soon as they are identified. Microscopic confirmation is made for each culture. Those showing no growth of tubercle bacilli are held for 3 months before they are reported.

Animal inoculations are made on the specimens as received, and the animals are sacrificed after 8 weeks. A few isolated specimens are treated before inoculation. Practicing physicians, physicians in hospitals, at tuberculosis clinics, at mental institutions, and in laboratories throughout the State send specimens. Occasionally, animal inoculation tests for virulence are requested by laboratories on cultures which they have isolated.

The following table shows how the examinations for tuberculosis were divided in 1951. About 5 percent more positives were found on culturing than by microscopic examination of the sputum concentrates.

	Total	Number positive	Percent positive
Microscopic examination for sputum concentrates.	5, 028	460	9. 1
Cultures on sputum con- centrates.....	4, 939	692	14. 0
Direct animal inoculations. Cultures on specimens for direct animal inocula- tions.....	1, 518	144	9. 5
Pathogenicity tests.....	1, 528	150	9. 8
	235	198	84. 3

The culturing of specimens establishes the identity of any acid-fast organisms. There are instances where acid-fast organisms are observed in stained smears of the original specimen but after growth on culture media, the colonial characteristics show they are not tubercle bacilli. It is a serious error when these other acid-fast organisms are reported to the physician in such a way that he is led to accept them as tubercle bacilli. There may always be doubt in the physician's mind even though follow-up X-rays do not show evidence of tuberculosis. Occasionally in our experience cultures have grown which closely resemble cultures of

culosis; cases moved out of State or unable to be located; and all cases with no status report for over 5 years. There are also an alphabetical, visible master index file with a small identifying card for each register case giving its file location and a punch card system for machine tabulation of data. Interchange of information forms patterned after the register card are used for forwarding reports from register to register.

A satisfactory register is possible only through the cooperative efforts of all concerned with the problems of tuberculosis control.

The Nurse Consultant

PHR In 85 of 169 Connecticut towns, the public health nursing organizations provide public health nursing service. There are only five boards of health with full-time health officers who employ public health nurses for the tuberculosis nursing service. In 43 towns without a local public health nurse, the State Tuberculosis Commission provides direct tuberculosis nursing service on request until local service can be established. Because of the different organizations offering tuberculosis nursing service, we have carefully planned an information referral system to provide continuous and integrated service to the tuberculosis patients.

Each one of the four public health nursing consultants of the commission is assigned to a sanatorium district for liaison between public health nurses, the sanatorium, the consultation service, and the State Tuberculosis Commission.

A Dual Role

The duties of a nurse consultant in Connecticut's tuberculosis control program are somewhat unusual. To the local public health nurses, she interprets the control program.

By Helen M. Green, R.N., senior tuberculosis control nursing consultant, Connecticut State Tuberculosis Commission.

She also participates in the student nurse program, in the follow-up of cases found through mass X-ray surveys, and in monthly conferences of State-employed public health nurses. It is her dual role with the sanatorium and the local community which makes her a valuable link in the control program. This can best be illustrated by a brief story of her work with a new supervisor in a local two-nurse agency and a typical tuberculosis patient, Mr. X.

The nurse consultant discusses plans for acquainting the new supervisor with the services and facilities in the State. During the period when the new nurse is gaining familiarity with her area and the health program, the consultant reviews statistical data on tuberculosis for the local community over the preceding 3 years (mortality, newly reported cases, and sanatorium admissions), and field reports, correspondence, and the State case register.

On her first visit to the new supervisor, she explains the functions of the tuberculosis commission and the types of referrals which will be sent to the local nurse, and she describes the consultation service. She suggests sample information literature which the Connecticut Tuberculosis Association makes available. Before her next visit, she reviews the case register in more detail to obtain information on patients recommended for sanatorium care, on patients awaiting admission, on ones who have refused sanatorium care, and on those who left the sanatorium against advice. On the second visit, both nurses will discuss specific cases and determine the nursing needs of each patient. The consultant arranges for the local nurse to observe a field consultation service which she also attends to explain the individual cases.

The Case of Mr. X

A week later, the local supervisor receives a report on a Mr. X who was examined at the consultation service. She calls his physician, who explains that he has received positive sputum reports on Mr. X and that sanatorium care is advised. The physician has talked to Mr. X and has completed the sanatorium application, but he requests the nurse to give the patient's family instructions about preventing further exposure. He has arranged for examination of the household contacts at the con-

sultation service. Knowing the importance of visiting as soon as possible after a diagnosis, the nurse calls at the home of Mr. X that same day.

During her visit, the nurse discusses the problems that are foremost to Mr. X and his family: how long he may be sick; are the children infected; where are the tuberculosis hospitals located; how is tuberculosis treated? She teaches Mr. X how to guard against spreading his infection. She explains the services offered by the community's medical and social agencies.

The nurse regularly visits Mr. X and his family to continue her teaching and to initiate a regime comparable to sanatorium routine. Any problems or questions she cannot answer, she communicates to the public health nursing consultant in the tuberculosis commission. Meanwhile, she completes a supplement to the sanatorium application for admission, mailing it to the commission, which will send a copy to the sanatorium with a copy of the application when the patient is assigned a vacancy.

When the patient's name nears the top of the waiting list, the consultant communicates with the local public health nurse to assure that Mr. X is planning to accept the sanatorium vacancy. The vacancy assignment is sent to the local nurse, who ascertains from Mr. X that all necessary preparations have been completed for his hospitalization. She also explains the procedure for cleaning his room after his departure from home. During his hospitalization, the local nurse visits his family and talks with the school nurse about his children and with the industrial nurse at the plant where he works.

At the Sanatorium

After Mr. X has been admitted, the nurse consultant attends the sanatorium staff conference when his case is presented, his films are reviewed, and plans for his treatment are discussed. She learns he is anxious about the health of his youngest child and notifies the local nurse, who visits his family and arranges for the child's examination. When Mr. X is scheduled for rehabilitation conference, the consultant inquires about his future plans. After the conference, she reports the rehabili-

tation plans for him to the local nurse. When she next sees him—about 2 months before his discharge—she discusses plans for his medical supervision after he leaves and emphasizes to him the importance of following the physician's recommendations upon discharge.

The local nurse is notified of the pending discharge with a request for the status of present home conditions. She helps prepare for Mr. X's homecoming by explaining his limitations and by pointing out the value of keeping him on a regular routine. The information about his present home conditions is presented at the sanatorium staff conference, if indicated, and is then attached to Mr. X's record for use at the final discharge interview. The local nurse visits Mr. X after discharge to assist in his readjustment to living outside the hospital community. Many patients need greater help here than was needed upon admission to the sanatorium.

Through this plan of referral, we have eliminated many of the gaps between the sanatorium and the home, and better continuity of patient care is provided with the two-way traffic of information until complete rehabilitation has been achieved.

Student Affiliation Plan

 Few States can match Connecticut's record in tuberculosis nursing affiliation. Since the start of the affiliation program in 1948, nearly 700 students have trained in the care of tuberculosis patients at State sanatoriums. Connecticut is among the first States in which the official agency responsible for tuberculosis control has acted to promote tuberculosis education for nursing students.

Before tuberculosis experience could be possible for student nurses, the requirements of the State board of examiners for nursing had to be

By Louise Lincoln Cady, R.N., nursing education coordinator, Connecticut State Tuberculosis Commission.

met as to instruction and nursing practice. Teaching materials had to be prepared. Communicable disease precautions had to be established at the sanatoriums accepting students, and nursing procedures had to be revised. Qualified instructors had to be secured. Standards of sanatorium patient care had to be set so that students could learn good nursing by observing it.

Student Practice

At first, only a few sanatorium wards could be opened to student practice. Today, experience in nursing practice has been extended to include the complete range of sanatorium facilities. At present, nursing students from 15 of the 21 nursing schools in Connecticut are affiliating with 2 State sanatoriums. At least 15 former students have returned to the sanatoriums as graduate nurses.

Through classes with the director of the tuberculosis commission, the physician in charge of surveys, the public health nursing consultant, and a representative of the Connecticut Tuberculosis Association, the student learns the fundamentals of epidemiology and tuberculosis control—an understanding which is furthered by observation at the State's consultation clinics and community surveys.

The greatest factor in overcoming possible fear of tuberculosis on the part of the student is a good student health program at the sanatorium. A new student is given a tuberculin test and a chest X-ray, followed by periodic check-ups during her affiliation and for 2 years after. To date, 92 nurses have completed the 2-year follow-up.

Since every member of the sanatorium nursing team participates in teaching and supervising nursing students, there must be a continuous education program for the professional and nonprofessional nursing staff. The duties of each member should be carefully defined, and an orientation program should be prepared for each type of worker. Staff education programs vary. One part of the affiliation program has been to give nurses special experience in conditions which may complicate tuberculosis.

Students add to their knowledge of tuberculosis by attendance at medical and surgical conferences. These in combination with observa-

tion opportunities at rehabilitation conferences increase their understanding of the needs of the patient as a person and his family problems.

Patient Education

In the two sanatoriums with student affiliations, the students are given an opportunity to supplement the instruction given to patients by registered nurses. A program of patient education includes individual instruction at regular intervals, group instruction conducted on the wards, classes for women patients in homemaking and diet, and classes for patients whose discharge is pending.

One result of the student program has been to increase the desire of nurses in general hospitals to know more about the care of the tuberculosis patient. Greater interest in X-rays of general hospital admissions and in good health programs for the nursing staff has been another outcome.

The Connecticut Tuberculosis Association has contributed financial assistance for speakers addressing students and for observation opportunities afforded staff nurses. The unlimited cooperation of the tuberculosis commission, the sanatorium directors, and the schools of nursing has been highly effective in providing many students with the opportunity of tuberculosis affiliation.

The Health Educator

 The health educator in the State Tuberculosis Commission acts as field representative in the organization of mass X-ray surveys in communities and industries. To be effective, he must know the mechanics of the complete program; he will plan programs with the physician in charge of surveys; he will coordinate activities of other staff members participating in survey organiza-

By William B. Parsons, M.S., assistant in health education, Connecticut State Tuberculosis Commission.

tion; and he will use the X-ray service as a springboard for health education.

A plan of procedure has been published outlining the operation of the mass survey, describing the committees required, and giving recommendations for avoiding pitfalls. The plan centers on an efficient appointment system which has been developed for smooth, continuous operation of the X-ray units.

Survey Committees

In making full use of his opportunity for health education, the educator acts as adviser to a local nucleus committee of well-informed, responsible citizens who are sincerely interested in the health of their community. The committee is usually composed of the over-all chairman of the survey and chairmen of canvassing, of appointments, of volunteers, of publicity, and of industrial arrangements. In addition, it includes the health officer, a representative of the public health nursing group, a practicing physician in the area, and a member of the town government. The health educator meets with the subcommittees on canvassing, appointments, and volunteers.

Several months before a survey, arrangements are made for talks before civic and fraternal organizations. Letters describing the purpose of the survey are sent to private physicians, ministers, clubs, and community groups. The publicity chairman and the health educator plan newspaper and radio announcements explaining the reasons for participating in the survey and the method of making reports. They arrange for posters, exhibits, and the distribution of leaflets descriptive of the survey procedures and results.

The Basic Facts

Because the canvassers are the ones who persuade their fellow citizens to participate in the survey, they must have the basic facts about tuberculosis. Each canvasser receives fact sheets and information booklets prepared by the health educator in preparation for "selling" the survey to the adult citizens of the town and for signing up individuals for appointment at the X-ray units.

The mechanics of the industrial phase of the mass X-ray survey program are simpler than

in community surveys, but the problem of education is more difficult. No individual appointments are made by employees, and, therefore, by consent of the management, question-and-answer meetings are held with the plant foremen and department heads. The plant nurse is a key person in the industrial phase. If the foreman feels he cannot answer a specific question, he can refer to her. Posters, leaflets, and announcements are placed in strategic plant locations. Unions assist in educating their members and in encouraging participation.

In promoting X-rays, we stress:

The X-ray is the best single means of discovering chest disease in the early stages.

Chest X-ray is a good way to protect oneself, one's family, friends, and fellow-workers.

Of all persons X-rayed, 97 to 98 percent will have essentially normal chests. Their negative survey reports reassure them and serve as a permanent record of their condition at that time.

It takes only a minute to be X-rayed at the mobile unit—No one has to undress for examination—Everyone gets a confidential report on his chest film.

If X-ray findings are suspicious, see a doctor.

Recent Developments In Sanatorium Treatment

PHR Medical and surgical treatments in the sanatorium have undergone revolutionary changes during the past decade, with even more dramatic changes in the past 5 years.

PAS and Streptomycin

Streptomycin, which was the first drug to show any notable antituberculous activity in the human, presented the two major obstacles of toxicity and development of resistance by the tubercle bacillus. Eventually, these barriers were markedly reduced and a satisfactory modality of administration was found. Para-

By Nicholas A. Marinaro, M.D., assistant superintendent and medical director, Cedarcrest Sanatorium, Newington, Conn.

aminosalicylic acid (PAS) was the next antituberculous drug to be discovered. Although possessing rather low levels of toxicity and resistance formation, its antituberculous activity was far less than that of streptomycin.

At the present time, these two drugs are administered in a combined intermittent regimen wherein 1 gram of streptomycin is given in one intramuscular dose every third day, and 12 grams of PAS are given by mouth daily in three divided doses. This method produces the maximal therapeutic effect with minimal toxicity and drug resistance. The exceptions are when streptomycin is administered intrathecally in meningitis and is given in 1- to 2-gram daily doses in tuberculous meningitis and generalized miliary tuberculosis.

None of these drugs are alone capable of producing a cure, particularly in tuberculosis of the lung. Usually some other form of therapy must be added to achieve complete control of the disease. Other drugs have been tested and found to be deficient in the treatment of human tuberculosis.

New Developments

The most recently discovered antituberculous drugs are the hydrazines of isonicotinic acid. They possess these valuable characteristics for treating tuberculosis, among others:

- Easy and cheap to manufacture.

- Easy to take by mouth.

- Rapidly absorbed in the gastrointestinal tract.

- Low toxicity.

- Quick dispersion throughout the body.

- Readily excreted through the kidneys.

However, we lack so much information concerning their effect on tuberculosis and about proper dosage, drug resistance, and other therapeutic measures that it is impossible to make any statement of their full value.

The surgical treatment of tuberculosis has paralleled medical advances. Many factors—better thoracic surgeons, better anesthesiology, available whole blood, antituberculous drugs, and better understanding of basic pathology and physiology in pulmonary tuberculosis—have assisted thoracic surgery in its developments.

Specifically, pneumonectomy, lobectomy, wedge and segmental resections, and pleuro-pneumonectomy are the recent surgical improvements which have occurred in the removal of tuberculous lung tissue.

The above-mentioned medical and surgical treatments are rarely used alone, but rather in combination. Former methods of treatment have not been discarded but have been re-evaluated in the light of recent advances. Pneumothorax, pneumoperitoneum, and thoracoplasty are still useful procedures when properly applied. Mental and physical relaxation and rest still are the foundation stones of treatment. Sanatorium treatment is more necessary than ever because a broad therapeutic program is based on the judicious use of all forms of therapy.

WHO Fellowships for U. S. Citizens Not Available

The 5th General Assembly of the World Health Organization adopted a resolution instructing the Director General to give preference in awarding fellowships for at least the next 3 years to candidates from underdeveloped countries. Funds, therefore, are no longer available to support fellowships for United States citizens.

Radioactive Waste Disposal

By CLINTON C. POWELL, M.D., and HOWARD L. ANDREWS, Ph.D.

WITH the increased use of reactor-produced isotopes in research, many organizations are today faced with the problem of the disposal of radioactive waste materials. Many of the materials are either too active to put into municipal sewer lines or are in forms not suitable for liquid disposal. Large isotope-production centers, such as Oak Ridge and Hanford, have special facilities for handling waste products, but the average urban laboratory is not so equipped. Space for storage until decay has proceeded to safe levels may be at a premium, and land burial is often difficult and of uncertain permanence.

Although land burial may be satisfactory in special cases, it is generally undesirable for several reasons. Obviously, extreme care must be taken to avoid seepage and the subsequent contamination of surface or ground water. The selection of a suitable burial site presents problems: An area which today appears unattractive for construction and habitation may very soon become desirable for a building program. After weighing these considerations and being forced

to remove one land burial depot, the National Institutes of Health decided upon burial at sea as the most satisfactory method of ultimate disposal for all radioactive wastes which cannot be safely admitted to the municipal sewage system.

Concrete Burial Vaults

The present system for disposal of radioactive wastes is the result of over 2½ years of experimentation with various containers and methods of sealing. Two types of containers determined unsuitable were steel drums and garbage cans. These roll if placed on their sides, are inconvenient to handle, and will disintegrate rapidly in sea water.

Standard, commercially available, concrete burial vaults were found to be satisfactory basic containers. Child-size vaults, 19¾ by 18¾ by 44 inches (outside dimensions), hold about 5.3 cubic feet of material and cost about \$25 each. The cost is negligible compared to the total cost of the average experiment using radioactive isotopes. Vaults are also available in larger sizes, up to 36 by 28 by 93 inches, for the disposal of large items of equipment not readily broken down, but the small size is more generally useful and more easily handled.

The burial vaults may be lifted by steel cables attached to the four lifting eyes cast in the bottom. Pending disposal, they occupy a minimum of space and may be stacked if allowable floor loading permits.

As waste products are brought in from the various laboratories, monitors pack them in the vault as compactly as possible. Containers of liquid wastes may be put in, usually without concentration of the materials. An alternate

Dr. Powell, now with the National Cancer Institute, National Institutes of Health, Public Health Service, was formerly radiation safety officer for the National Institutes of Health, Bethesda, Md. Dr. Andrews is chief of the section on nuclear radiation biology, National Institute of Arthritis and Metabolic Diseases, National Institutes of Health. All members of the radiation health protection group at the National Institutes of Health have contributed to the development of the system for disposal of radioactive waste materials described in this report.

method involves mixing the liquid wastes with a prepared sand-cement mix; this is allowed to harden and then placed near the center of the vault. Dilute solutions may be concentrated by chemical reactions, evaporation, or ion exchange columns before disposal. Contaminated furniture, such as hoods, is taken apart for more compact stowage. Relatively active materials are placed near the center of the vault to reduce the radiation level at the outside by both distance and shielding. At the present time no attempt is made to concentrate routinely either solid or liquid wastes, but this will be done in the future as suitable methods are developed.

The vaults are filled with waste materials to within 3 to 4 inches of the top, then filled flush with a concrete mix. The mix is made with somewhat more than the usual amount of water to facilitate a complete filling of all voids which would add to the buoyancy and increase the chance of crushing by external water pressure. The final pouring is made with the vault suspended by the steel cables so that subsequent lifting will not crack the concrete cap. The finished product, ready for disposal, weighs from 900 to 1,300 pounds and is readily handled with a small chain hoist. The sealed container is weighed carefully to insure that it has a substantial negative buoyancy.

Concrete burial vaults sealed as described should also be satisfactory where land burial rather than sea disposal is practiced. Contact between the active contents and surrounding earth and water will be minimized, and removal will be facilitated if a new burial site has to be used.

Disposal at Sea

When a load of from 10 to 20 tons has accumulated, the vaults are trucked to the United States Coast Guard moorings at Berkeley (Norfolk), Va. To date none of the shipments has presented any radiation hazard to the truck drivers or handlers, but all shipments are routinely accompanied by a monitor in case of accident. The vaults are loaded from the pier to the deck of a Coast Guard cutter, using the

ship's cargo winch for hoisting. The load is put overside in not less than 1,000 fathoms of water, which in the Norfolk area means from 75 to 100 miles off shore. Bearings of each disposal point are taken by the navigator of the cutter, reported to the monitor accompanying the shipment, and later recorded.

Each discarded vault represents almost a monolith that will probably not disintegrate appreciably in 100 years. Since the seal between the cement cap and the body of the vault is probably not watertight, and no attempt is made to make it so, there will undoubtedly be a slow diffusion of material through this joint. Contamination by diffusion should be very small, however, and dilution by surrounding sea water very great. Radioactive decay during the period the structure is intact will reduce the activity of most commonly used isotopes to undetectable levels. Even 5.3-year Co^{60} will decay to nearly 1/1,000,000 of its original activity in 100 years. If the block eventually crumbles and exposes the contents, any undecayed products will be greatly diluted with large volumes of sea water.

Conclusions

It seems unlikely that this method of disposal, even if practiced by the majority of isotope users except the Atomic Energy Commission production plants, will have any detectable effect on commercial or sport fishing. The radioactivity associated with the potassium normally present in sea water amounts to about 1,000 curies per cubic mile, and the natural radium content of sea water will average perhaps 4 curies per cubic mile. It is most unlikely that these levels would be appreciably augmented by even a large-scale disposal program.

Disposition at depth appears to answer most of the objections to land burial and is much to be preferred to indiscriminate dumping into sewerage systems. A still greater factor of safety might be obtained by disposal in one of the stagnant areas where circulation with the bulk of the ocean water is relatively low, but these areas are less accessible than the one presently in use.

Radiological Health Field Training Unit

By SIMON KINSMAN, Ph.D., and MORTON I. GOLDMAN, M.S.

ALTHOUGH the radioactivity associated with radioisotopes and nuclear power is potentially of great benefit to mankind, it presents certain hazards which are becoming of increasing public health significance. These hazards are formidable but not insurmountable. Feasible methods of radiation protection are available for both the individual working in close contact with radiation and the public living in the environs exposed to radioactive wastes.

One of the most important aspects of radiological safety is the detection of radiation. Since radiation cannot be detected by our ordinary senses, we must depend upon special equipment to detect and measure it in order to preclude excessive exposure of individuals or the public.

State and local public health agencies will be, and, in fact, already have been, called upon to take an active part in radiological safety programs. Recognizing the nation-wide lack of public health workers trained in radiological safety procedures, the Public Health Service has instituted a series of short courses in radiological health at the Environmental Health Center in Cincinnati, Ohio. The mobile radiological health field training unit is an outgrowth of suggestions from the trainees of these courses and the realization of means to fulfill the numerous requests for field training.

The training unit was conceived in November 1950. Design and planning began the following month, and procurement of priority ma-

terials was in progress by March 1951. The majority of the interior construction, mounting of instruments, and installation of cabinets, sinks, and electronic radiac instruments was accomplished by members of the radiological health training section of the Environmental Health Center. The unit was completed in February 1952.

Radiation detection apparatus of each of the three functional types are contained in the unit: laboratory-type assay equipment, field-survey monitoring instruments, and personnel-monitoring devices. The assay equipment includes proportional, Geiger-Mueller, and scintillation counters plus associated scalars, count-rate meters, and recorders, all of which can be used for radiological assay of water, food, and air. These laboratory-type instruments are mounted in such a manner in the unit that they can be used in place or can be easily moved to a laboratory or lecture hall for training purposes.

The portable survey instruments include Geiger-Mueller counters, ionization chambers, and electrosopes. The personnel-monitoring devices include dosimeters and film badges, as well as a densitometer for reading exposed-film densities.

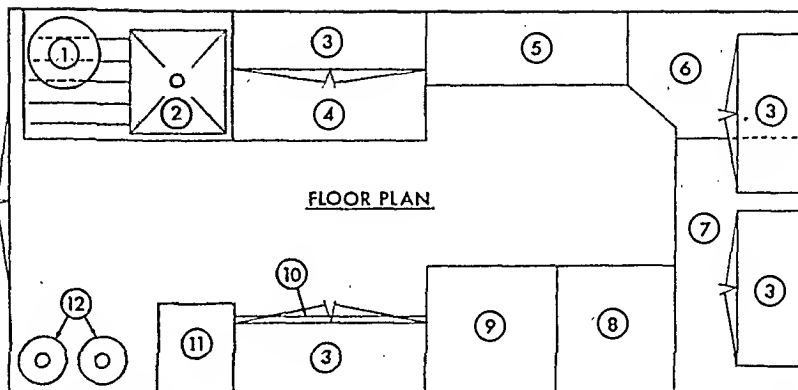

A chemical work table and exhaust hood are provided for the demonstration of safe radiochemical techniques and sample preparation using materials at low and intermediate radiation levels. Laboratory apparatus and glassware of the types used for tracer radiochemistry are included in this section of the unit.

To maintain the electronic instruments at proper operating temperatures and to provide a constant temperature for developing and servicing film badges, the unit is air-conditioned. It contains its own pressure water system and

Dr. Kinsman is chief and Mr. Goldman is senior assistant sanitary engineer of the radiological health training section, Environmental Health Center, Public Health Service, Cincinnati, Ohio.

electrical power supply (motor-generator) so that it can operate independently of municipal services. With slight modifications the unit can be used as a mobile field radiological laboratory.

The mobile unit is approximately 20 feet long

and requires about 35 feet for curb parking. The electrical service required is 3-wire, 115/230-volt, single phase a. c. with a demand of approximately 5,000 watts. The water system of the unit can be connected to an external supply through a garden hose, although the

internal supply will provide about 10 gallons under pressure and is used when no other supply is available.

The field training unit was first exhibited in Galveston, Tex., in conjunction with the annual meeting of the Texas Public Health Association in February 1952. At the conclusion of this meeting, the training unit was exhibited in Houston, San Antonio, Fort Worth, and Dallas. In March 1952, the unit was used in conjunction with a training course sponsored jointly by the Alabama State Health Depart-

ment and the University of Alabama and conducted by the radiological health training section, at Tuscaloosa, Ala. From June 26 through 28, the unit was exhibited at the University of Michigan at Ann Arbor in connection with the Fifth Annual Summer Institute on Industrial and Legal Problems of Atomic Energy. In addition, the unit is used for field exercises which are a part of the radiological health courses offered at the Environmental Health Center.

Public Health Service Staff Assignments

Dr. Price

Changes in staff assignments in the Public Health Service recently announced include the following:

Dr. David E. Price, associate director of the National Institutes of Health for the past 2 years, has been named Assistant Surgeon General. He will assist the Surgeon General and the Deputy Surgeon General in the administration of the Service. Dr. Price received his medical training at the University of California School of Medicine at San Francisco, and his doctorate in public health from Johns Hopkins University. A commissioned officer since 1941, his early assignments were in venereal disease control. In 1946 he came to the newly created Research Grants Division and became chief in 1948.

Dr. C. J. Van Slyke has been named associate chief of the National Institutes of Health, succeeding Dr. Price. The first director of the National Heart Institute (since 1948), Dr. Van Slyke's principal responsibilities will be the coordination of the Institutes' programs of research and training grants, disease control and community services, professional training, and relationships with national foundations and health organizations.

Dr. James Watt, for the past several years in charge of the National Microbiological Institute's field laboratory at Louisiana State University Medical School, has been designated the new director of the National Heart Institute. Dr. Watt is known both here and abroad for his work in the enteric and rickettsial diseases.

Mark D. Hollis, chief sanitary engineering officer of the Public Health Service since 1948, has been named deputy chief of the Bureau of State Services. As associate chief of the bureau, Mr. Hollis has been directing the Service's environmental health activities.

Harry G. Hanson, recently serving as executive officer for program in the office of the Surgeon General, will serve as assistant chief sanitary engineering officer.

Paul A. Caulk, formerly executive officer for administration, is now executive officer in the Office of the Surgeon General.

Dr. Joseph O. Dean, formerly associate bureau chief for staff and management services in the Bureau of State Services, has been transferred to the newly created post of associate chief for program development.

Dr. Jack C. Haldeman has been assigned as assistant chief of the Bureau of State Services for regional office and external operations. Formerly he was chief of the Division of State Grants.

Mental Health Screening of School Children

By CHARLES A. ULLMANN, Ed.D.

THE POLICY in community psychiatric clinics of leaving entirely to the patient or his family the responsibility for the decision to seek psychiatric help follows the pattern prevailing in private medical practice. By following this policy, publicly supported psychiatric services tend to focus on those members of the community who are already ill and are perceived as being ill either by themselves or their families.

There is a need to study whether this self-identification policy, in which the essential element is that the initiative must come primarily from the patient or his family, is the most efficient or appropriate basis for the initial selection of patients in clinics whose primary concern is public or community mental health. In time, it may also be necessary to examine the appropriateness of those considerations which commonly enter into the decision as to which of the self-identified applicants obtain treatment services. Some of those considerations are: apparent urgency of the patient's problem, the adequacy of the patient to his life role, estimates of therapeutic promise, economic circumstances, degree of professional interest in the patient's particular problem, immediate availability of therapeutic time, and/or patient's capacity to survive a clinic waiting list.

For public health programs which are geared to preventing illness and promoting the community level of health beyond the point of mere absence of disease, it may be desirable to replace the "trapper" technique of self-identification with the more selective techniques of the hunter. In case-work terms, this means relating clinic intake policy to community needs as defined by survey or screening, developing referral techniques which will permit selection of those cases

This article is a discussion of the principal findings presented in Public Health Monograph No. 7, published concurrently with this issue of *Public Health Reports*. The author is the clinical psychologist on the staff of the Prince Georges County (Md.) Mental Health Clinic, a demonstration activity of the Public Health Service, sponsored jointly with the Maryland State Department of Health and the Prince Georges County Health Department. The studies reported were conducted during the school year 1950-51 by the clinic in cooperation with the Prince Georges County Board of Education. The basic findings were presented before the American Psychological Association at its sixtieth annual meeting in Washington, D. C., September 1-6, 1952.

. . .

Ullmann, Charles A.: Identification of maladjusted school children. Public Health Monograph No. 7 (Public Health Service Publication No. 211). U. S. Government Printing Office, Washington, 1952.

upon whom the expenditure of professional time will give the greatest return in terms of community mental health, and evolving a

rationale for formulating and assessing therapeutic goals.

This paper summarizes the results of a study which is reported in full in Public Health Monograph No. 7, "Identification of Maladjusted School Children." The study deals with the first of the aforementioned questions of policy and method, namely, a survey of the nature and extent of the mental health problem presented by a group of ninth-grade children in a public school system. The investigations were made in an effort to develop a method for identifying those who might need assistance because of problems of adjustment. The problem of effectuating suitable referral techniques, including bringing about an emotional acceptance of the need for service on the part of persons who may be deemed maladjusted, and the problem of establishing guidelines for therapeutic activity, were considered beyond the scope of the study.

The Maladjusted Child

In the study, an attempt was made to learn to what extent judgments by teachers might be relied upon as a means of identifying children who needed special assistance because of adjustment difficulties, that is, an examination was made of the correlation between need for mental health services as expressed in teachers' judgments and need as determined from independent reference points. These independent reference points were the classmates of pupils, each pupil himself, and the opinions of clinicians who were asked to rate the significance for mental health of various items of behavior. Such questions were considered as: To what extent are children who are identified as maladjusted by the teachers the same ones whom classmates would identify as being maladjusted? In terms of clientele who may be served by a mental health clinic, what are the implications of relying upon such key figures as teachers to identify school children who need care? Is there evidence of need for mental health care beyond those needs which are recognized by such observers as teachers? What is included in the term "maladjustment" as used in the school setting? To what extent do teachers and clinicians agree on what constitutes evidence of maladjustment?

Psychological or psychiatric assistance, as used in this context, may be regarded as a service which supplements or reinforces the counseling and guidance services upon which all pupils may draw as they progress through the successive phases of their education. As such, it may be used to support the pupil, parent, school staff, or community in the effort to achieve broad educational and health purposes whenever the classroom program and pupil personnel services ordinarily available require supplementation. While the relationship between such general and special services will vary from place to place and from time to time, according to the relative strength and adequacy of each, the methods employed in this investigation are of general applicability in that the testing and rating techniques are suitable for typical classroom use.

The subjects of the main study were 404 white ninth-grade boys and 406 white ninth-grade girls in the core classes of 23 teachers—21 women and 2 men—in Prince Georges County, Md., during the school year 1950-51. The experimental sample included 97.5 percent of the pupils on the register in these classes and 44.5 percent of the ninth-grade registration in the white public schools of the county. Only one core class was included for each core teacher who participated. Whenever two classes were taught by the same teacher, deliberate choice of the more literate class was made for this study, on the basis of the teacher's judgment.

Forced-Choice Technique

A collateral study was carried on in grades four to eight during the fall of the same school year for the purpose of developing a Forced-Choice Test which, when completed, was used in the study at the ninth-grade level. Forced-choice technique is employed for the purpose of minimizing intentional bias on the part of raters and aiding raters to make more discriminating judgments when bias is not a factor. The essential feature of such tests lies in the pairing of one statement or item, capable of discriminating between upper and lower groups on a trait, with another item which does not have discriminative power but appears equally attractive to raters. Pairs of such state-

ments are often combined into tetrads and raters are then required to choose the most appropriate statement of the tetrad to describe the ratee.

In order to discover the discriminative power of each statement in the eyes of mental health specialists, 22 clinicians were asked to rate each of 194 statements on a 5-point scale of significance for mental health. At the same time, each of 50 teachers was asked to rate on a 5-point scale one "well-adjusted" child and one "maladjusted" child according to the degree to which each statement characterized the child. The correlation between the discriminative power of each statement, as obtained from the clinicians, and the discriminative power, as obtained from the teachers, was 0.86. Teachers and clinicians were in closer agreement on favorable than on unfavorable statements.

While it appeared that clinicians and teachers agreed on the significance of most of the items as indicators of adjustment, they differed on the meaning of politeness and obedience. Teachers felt that politeness and obedience were characteristic of good adjustment whereas clinicians felt that the significance of these items as indicators of adjustment was equivocal. Also, a number of features upon which clinicians rely in judging the adjustment status of children are matters relatively unavailable to classroom teachers, such as preference on the part of a child for associating with a different age or grade group than the one to which he is assigned

Measures of Adjustment Status

Six measures of adjustment status were then obtained for each ninth-grade child:

1. From teachers, a categorical rating of each child as well adjusted, moderately maladjusted, or seriously maladjusted, together with an estimate by the teacher of whether this rating was given with much, some, or little confidence.

2. From teachers, an adjustment score on the specially constructed Forced-Choice Test.

- 3, 4, 5. From pupils, adjustment scores on the Self and Social components of the California Test of Personality Intermediate Form A and the Basic Difficulty Scale of the SRA Youth Inventory Form A.

6. From classmates, a standard score derived from sociometric ratings of probable occupational adequacy.

Teachers thought that 8 percent of the ninth-

grade children were likely sooner or later to have serious problems of adjustment and to need special help or care because of such problems. In 1927, Wickman reported that teachers considered 7 percent of elementary school children to be serious behavior problems. An intervening study by Rogers in 1940, using multiple criteria, of which teachers' judgments were but one, assessed an even higher percentage (12) of children in the first six grades as seriously maladjusted. Although allowance must be made in these comparisons for differences in sampling, phrasing, and basis of assessment, it appears that teachers regard serious maladjustment and, presumably, the need for mental health assistance, to be at least as great now as at the time of the Wickman study.

Data from all three of these studies and data from juvenile courts and psychiatric clinics agree in reporting more maladjusted boys than maladjusted girls. The ratios vary from 1.4 boys to 1 girl in psychiatric clinics to more than 4 boys to 1 girl in courts. This ratio is reversed among adult applicants to psychiatric clinics, where women outnumber men. In the present study, and in the Wickman study, teachers rated four boys seriously maladjusted to every girl so rated.

Classmates, to an even greater extent than teachers, considered boys to be more maladjusted than girls, so that, regardless of the merit of the judgments, it appears that boys receive, in the combined criticisms of peers and teachers, a much greater volume of adverse appraisal than do girls, with such further effects on boys as that disapproval may itself occasion.

There was a marked difference in the way teachers as a group rated boys and the way they rated girls. The teachers gave the girls more favorable ratings than the boys and felt more confident of these ratings, notwithstanding the fact that teachers' ratings for girls bore relatively little resemblance to the way the class as a whole rated girls or to the way the girls felt about themselves. This is shown by correlations no higher than 0.23 between teachers' categorical ratings and measures obtained either from classmates or from self-descriptive personality tests. Teachers' ratings of boys, however, showed a much closer relationship to

classmates' ratings than did teachers' ratings of girls.

The confidence felt by teachers in their ratings was found to vary with the merit of the rating rather than the sex of the child; that is, teachers felt confident about a rating which was favorable regardless of whether they were rating a boy or a girl.

On the basis of these data, it was hypothesized that teachers' ratings of girls were favorable because the teachers lacked opportunity to observe or lacked awareness of the manner in which girls made their significant adjustments, and that favorable ratings were often awarded to girls in the absence of positive evidence indicating that unfavorable ratings should be given. In the case of boys, adverse ratings appeared to have been given in the presence of evidence derived from acted-out behavior. This hypothesis appeared to be supported by a study of the characteristics and interrelationships of the remaining measures employed with the ninth-grade children, as shown below.

It appeared, from the data obtained in grades 4 to 8, that teachers rated most comfortably those items of behavior which came closest to their day-to-day experience with children, namely, attitudes toward and habits of school work. They felt less confidence in rating aspects of children's behavior which referred to home or social relationships, to passive hostility, and to matters about which children worry.

The Forced-Choice Test, employing items to which teachers felt they could respond with confidence, focused mainly on objectively observable aspects of behavior. With this test the ratio of boys to girls rated maladjusted by teachers was raised over that found when teachers assessed children categorically and also over that found with ratings by peers. The correlation of the two methods of obtaining ratings by teachers, categorical and forced choice, was much higher for boys (0.73) than for girls (0.43). Use of this test resulted in a substantial (0.49) correlation between ratings of girls by teachers and ratings of girls by classmates, in contrast to the low (0.23) correlation obtained when teachers rated the girls categorically. In the case of boys, a substantial correlation appeared between teachers'

categorical ratings and sociometric ratings. This was not significantly altered by the introduction of the Forced-Choice Test. The Forced-Choice Test acted as a kind of telescope which, while it failed to add to the picture of boys obtained through teachers' unaided vision, permitted the variations in girls' adjustment to become apparent.

Personality Tests

Whereas ratings, as exemplified by the Forced-Choice Test, dealt with observable evidence, the personality tests relied mainly on report by the subject of his own feelings and attitudes. Focusing upon items of "observable" or acted-out behavior tended to increase the imbalance against boys; focusing upon "subjective" data had the opposite effect; that is, it tended either to minimize this imbalance or to show the girls to be more maladjusted than the boys, as exemplified by the results on the SRA Youth Inventory Basic Difficulty Scale. Furthermore, according to the published normative data, girls acknowledge much more often than boys feeling disturbed about the problems included on the Basic Difficulty Scale. Of the list on which girls feel more disturbed, they exceed boys by the greatest amounts in the following:

	Boys (per- cent)	Girls (per- cent)
I worry about tests.....	34	52
I worry about little things.....	26	44
I'm easily excited.....	14	32
I have a "crush" on an older person.....	4	13
My feelings are easily hurt.....	19	39
I'm afraid to speak up in class.....	15	29
I have frequent headaches.....	7	16

Boys respond in higher percentage than girls on the following five items:

	Boys (per- cent)	Girls (per- cent)
I think about sex a good deal of the time.....	17	8
I am too restless to stay in school.....	10	5
My teachers are too strict.....	9	5
I'm losing faith in religion.....	8	5
Is it wrong to deny the existence of God?.....	9	6

It is of particular interest to note that while teachers felt very little confidence in their ability to make ratings on items having to do with children's tendency to worry, such items are among those which, on the SRA Youth Inventory, differentiate the adjustment problems of girls most sharply from those of boys. This observation and the fact that the correlation of teachers' ratings and sociometric ratings is increased so much for girls when a forced-choice technique replaces the categorical method indicate that teachers do not readily react to the symptomatic aspects of girls' adjustment.

Essentially different pictures of the adjustment of children are obtained whenever children's adjustment is assessed through judgments by raters and through judgments from self-perceptions. Teachers' ratings of adjustment and sociometric ratings obtained from classmates showed a much closer relationship to each other than to scores on personality tests. Adjustment scores on self-descriptive personality tests also correlated more highly among themselves than they did with ratings. Correlation coefficients between measures representing each of these approaches or categories of measurement (that is, ratings by observers versus adjustment scores on self-descriptive personality tests) were low, ranging from 0.15 to 0.33. The correlation between teacher and sociometric ratings was 0.56, and the correlations among the personality tests ranged from 0.47 to 0.73. The size of the correlation (0.61) between two tests of dissimilar format and content (SRA Basic Difficulty and California "Self" scores) suggests that they are measuring a meaningful attribute of the personality. Ratings were more highly intercorrelated for boys than for girls and self-descriptive personality test scores were more highly intercorrelated for girls than for boys.

Summary

On the basis of the study of white ninth-grade public school children, the assessment of maladjustment appears to require at least two approaches, each of which is sensitive to a particular class of symptoms. Ratings appear to be better predictors of the response by society to acted-out behavior, and self-descriptive data appear to be better predictors of that aspect of adjustment which has to do with feelings, attitudes, inner tensions, and what the individual himself will choose to do. Children identified as maladjusted by each of these two general methods are likely to exert considerably different demands upon therapeutic time and upon health, welfare, and educational funds. This problem ultimately may be reducible to comparing the present defiance of authority on the part of a boy and the probability that he will be taken into juvenile court with inner tensions on the part of a girl and the probability that as an adult she will make application in her own behalf at a mental health clinic.

For the present, both types of measure (ratings by observers and self-descriptive data) appear to be necessary to a full picture of adjustment status. Further research may appropriately be directed toward examining the specific criteria for which each type of predictor is valid.

As a result of fractionating the term "maladjustment" into two components, each of which has a potential relationship to different forms of behavior, two questions are posed for future study: (1) the relative degree to which persons of each type present a significant locus of concern for public mental health programs, and (2) the extent to which various techniques of discovery and referral are appropriate for the mental health needs represented in these two varieties of symptomatic behavior.

Rodent Control Series

16 mm., sound, black and white, 1951.

Audience: Public Health personnel and others interested in the study of rats and the practice of rat control. Sections of it may be of interest to school groups.

Available: Loan—Federal Security Agency, Public Health Service, Communicable Disease Center, 50 Seventh Street, Atlanta, Ga. Purchase—United World Films, Inc., 1445 Park Avenue, New York 29, N. Y.

This series of seven films, produced jointly by the U. S. Army and the Public Health Service, is based on footage obtained by filming rats over long periods under conditions simulating natural ones as nearly as possible. A yard was prepared containing food and terrain favorable to rat life, and the rats were conditioned, over a period of time, to the noise of the motion-picture camera and the necessary lighting arrangements, so that they came to ignore them. Cut-away embankments with glass facing were prepared in order to make visible the burrowing habits of the rats.

1. *The Rat Problem*—M37a, 25 minutes

The extent and seriousness of the health hazards and economic damage created by rat infestation are emphasized, both in terms of history and the present. This film develops the idea that study of rat habits and living patterns is necessary to the practice of effective control.

2. *Habits and Characteristics of the Norway Rat*—M37b, 28 minutes

The Norway rat is described in detail and compared with the roof rat

as to size, strength, and features; the living pattern is shown, including feeding habits, breeding habits, and the environmental factors which allow the rats to flourish.

3. *Habits and Characteristics of the Roof Rat*—M37c, 14 minutes

Similar to No. 2 in the series, this film describes the roof rat and compares and contrasts its habits and abilities with the Norway rat. The emphasis is on what these characteristics mean in terms of the rat's relation to man.

4. *Practical Rat Control—I, Sanitation Techniques in Rat Control*—M37d, 21 minutes

Using the film record of the rat's living and food gathering habits, the film shows practical methods for eliminating factors necessary for the rat's existence. Emphasis is on the proper disposal of garbage, storage of food, and cleanliness.

5. *Practical Rat Control—II, Ratproofing*—M37e, 18 minutes

Rats are observed pitting their strength and gnawing abilities against various test materials. On the basis of these demonstrations, the proper methods are shown for preventing rats from gaining entry into a building or buildings, either by burrowing, or by getting in above ground.

6. *Practical Rat Control—III, Rat Killing*—M37f, 36 minutes

This film shows the advantages and disadvantages and the techniques for using such rat poisons as red squill, ANTU, arsenic trioxide, 1080 water, and warfarin, and for using rat traps. The film emphasizes that for effectiveness of these

techniques, sanitation and ratproofing are essential.

7. *Rat Ectoparasite Control*—M37g, 12 minutes

The importance of the rat flea in transmitting disease from rat to man is stressed, as well as the increased incidence of human infestation when the rat host has been killed. Methods for eliminating the rat flea population with DDT before attempting to kill the rats are described in detail. The film emphasizes the importance of rat control—sanitation, ratproofing, and rat killing—in conjunction with control of rat ectoparasites, for the complete elimination of rat-borne diseases.

Rural Rat Control

16 mm., sound, black and white, 16 minutes, 1951.

Audience: Public health personnel and others concerned with rat control.

Available: Loan—Federal Security Agency, Public Health Service, Communicable Disease Center, 50 Seventh Street, Atlanta, Ga. Purchase—United World Films, Inc., 1445 Park Avenue, New York 29, N. Y.

This film shows how the conditions on a typical farm favor the growth of rats by providing them with food sources and suitable harborage. The methods of ratproofing buildings and food sources, and the measures for sanitary garbage disposal are described in detail. Methods are

also shown for poisoning the rats, which are now deprived of food and harborage, by using red squill, calcium cyanide, and warfarin. A check of the effectiveness of the rat control and a continued vigilance against further invasion is the use of talcum powder or flour to detect rat tracks.

New York State Cancer Control Program

By VINCENT H. HANDY, M.D., M.P.H. and PAUL R. GERHARDT, M.D., M.P.H.

CANCER, one of the major disease problems of our day, is one of our chief public health problems. In recent years, its control has become a prime concern of the medical profession, the health agencies, and the public. Public interest and public demand for action have been motivated largely by fear and alarm over the increasing incidence of and the high mortality from cancer. Cancer control may be defined as an organized, planned endeavor to apply the principles of prevention, early diagnosis, prompt and adequate treatment, and care—including the provision of the best care and comfort to those in the advanced stages of cancer.

In carrying out the objectives of cancer control, the New York State Department of Health plans and works in cooperation with the district, city, and county health departments, the organized medical and dental professions, the New York State Division of the American Cancer Society, the State department of social welfare, medical schools in the State, nursing associations, various research centers, and the Public Health Service and its National Cancer Institute.

The Program

In any one year, cancer afflicts well over a half million people in this country. On the basis of Levin and Goldstein's study of cancer incidence, mortality, and expectancy (1), we can predict that a 20-percent minimum of all

persons in New York State will develop cancer during their lifetime.

All data reported herein for New York State, except where indicated, are exclusive of New York City. Likewise, the terms "upstate New York" and "upstate area" refer to New York State exclusive of New York City.

In 1951, 19,449 new cases of cancer were reported. At any one time in the upstate area, it is estimated that approximately 50,000 persons have cancer in various stages. The amount of work ahead is overwhelming and provides a scope of action for all professions and organizations.

New York State's interest in cancer control activities has a long history, beginning at the end of the 19th century. In 1898, Dr. Roswell Park, a Buffalo surgeon, persuaded the State legislature to grant \$10,000 for the institution of the State pathological laboratory in the University of Buffalo School of Medicine. Roswell Park Memorial Institute, the State cancer hospital in Buffalo, has developed from that source. A division of cancer control was established in 1931 at the institute with public education as its chief function. Upon recommendation of the New York State Legislative Cancer Survey Commission in 1939, cancer was made a reportable disease in the State, exclusive of New York City; the cancer control division was transferred to the State health department in Albany and its functions were broadened to permit the development of a more comprehensive program.

These beginnings and our progress since were made possible with the active support and influence of the medical profession and the citizens of the State. In more recent years,

Dr. Handy is assistant director and Dr. Gerhardt is director of the bureau of cancer control, New York State Department of Health.

this support and public action has produced a well-organized and active voluntary health agency: the New York State Division of the American Cancer Society.

The programs of the New York State Division of the American Cancer Society and of the State health department supplement and complement each other. On the State level, key personnel in cancer control serve on the board of directors and executive committee of the society. On the county level, local physicians, health officers, and the nurses take an active part in its program.

To point out the important contribution of the New York State Division of the American Cancer Society, one need only mention a few of the many projects for which funds have been allocated in the past year. Among these are financial support to tumor clinics and detection centers, payment for cytological and pathological services in some areas, intensive public educational programs, establishment of information centers or "Friendly Red Doors," nursing services, follow-up studies, professional fellowships, limited financial aid to needy cancer patients, and the development of a large and active volunteer group of workers.

The cancer control program of the department of health aims to assist all the people of the State in obtaining the best medical service for prevention, diagnosis, treatment, and care of cancer, and to advance knowledge with respect to its control. It covers eight basic fields: public education; professional education and training; cancer reporting; pathological diagnostic service; nursing services and training; promotion of tumor clinics; promotion of detection centers; and maintenance of a State cancer hospital.

Public Education

The necessity is well established for constant education of the public regarding the importance of prompt medical care for various symptoms and of periodic physical examinations in the absence of symptoms. Public education is carried on by means of pamphlets, lectures, sound movies, radio and television programs, and exhibits. Most of the county medical societies have speakers' bureaus through which

trained medical speakers are available to public groups for cancer education talks. Participating physicians may be reimbursed \$10 apiece by the department's bureau of cancer control. The local branches and the "field armies" of the State division of the American Cancer Society have played an important part in stimulating community interest in the lectures.

In all, 727 public cancer education talks to 38,985 persons were reported in 1951 for the upstate area, representing an increase of 27 percent over the 531 talks reported for 1948. Unquestionably, others were not reported. Our figures show that over half the talks were given by local physicians in their respective areas, indicating the extent of physician participation at the local level.

Professional Education and Training

Professional education must be a major activity of any cancer control program, for the physician is the one individual upon whose shoulders rests perhaps the greatest responsibility. Frequently, life and death depend on his efforts to recognize precancerous lesions, to diagnose cancer early, to render adequate treatment, and to secure competent consultation. A description follows of the many types of professional education employed throughout the State.

Medical Society Meetings. Many medical societies periodically have speakers on cancer at their regularly scheduled meetings. If desired, an honorarium of \$25 can be obtained for the speaker through the bureau of cancer control of the State health department.

Cancer Teaching Days. An effective means of professional education for both medical and dental groups is the cancer teaching day. A program of afternoon and evening lectures and demonstrations by invited authorities is offered on various aspects of cancer diagnosis, treatment, or research. Physicians from surrounding counties are invited to attend. The cancer teaching days are sponsored by the New York State Medical Society, the county medical societies, and the State and local health departments. The State health department pays an honorarium of \$50 to each speaker.

Literature. One aspect of professional education has been an attempt to prepare and distribute cancer literature of interest to the professional person. During the last 2 years, the department has distributed:

"Cancer Nursing Manual"—to each public health nurse in the State.

"Program Plan—Cancer Control"—to all physicians in the State, exclusive of New York City.

"Occupational Cancer Manual"—to each physician in the State.

"Cancer Control in Public Health"—to all local health officers in the State with the exception of New York City and to members of the Public Health Cancer Association of America.

Tumor Clinic Conferences. In accordance with the recommendations of the American College of Surgeons, local hospitals are urged to use their tumor clinics for professional education. The bureau of cancer control has encouraged tumor clinic staffs to bring in consultants from other areas and medical centers wherever possible to hold clinical sessions and physicians' conferences. For this type of service, the bureau reimburses qualified consultants at a rate of \$50 a day.

Teaching of Tumor Pathology. A joint project of the State health department and the Memorial Hospital in New York City, the program of teaching tumor pathology was begun in 1948 and continued with a special grant from the National Cancer Institute of the Public Health Service. Teaching material consists of slides and complete clinical histories of selected cancer cases prepared at Memorial Hospital and then distributed by the department's division of laboratories and research to pathologists in charge of the 144 approved laboratories in the State (2).

Fellowship Program. Fellowships are available to aid physicians in obtaining postgraduate experience or training in fields relating to cancer control. The candidate physician usually applies directly to the source from which he intends to obtain his training, whether it be a hospital, a clinic, or an independent medical specialist. Upon acceptance, he applies to the department for a fellowship to help in payment of tuition, and to include a monthly stipend of \$300 and traveling expenses. Any physician residing in the State is eligible, provided the training will benefit the cancer con-

ROSWELL PARK MEMORIAL INSTITUTE BUFFALO N.Y.

Architect's drawing of addition to Roswell Park Memorial Institute, Buffalo—the New York State cancer hospital.

trol program. Usually, applicants are physicians associated with tumor clinics or detection centers, or are pathologists wishing additional training in cytology. Fellowships may be granted for a week to a year and have included training in surgery, medicine, pathology, radiology, otolaryngology, and gynecology. From the beginning of the program in May 1947 until July 1, 1952, 84 New York State physicians have received a total of 2621¼ months' training.

Postgraduate Courses. Several different types of courses have been organized during the last few years at different centers.

In 1949 and again in 1951, a 2-day postgraduate course on malignant diseases was held for the general practitioner in Buffalo. This was possible through the cooperation of the University of Buffalo Medical School, the Erie County Medical Society, and the Erie County and State health departments. Tuition of \$20 per physician was paid by the State health department. It is hoped to continue the course on a yearly basis and to start similar courses in other medical centers.

A 2-week course in cancer diagnosis and treatment was given in 1952 by the Columbia University faculty of medicine at the Francis Delafield Hospital in New York City, and sponsored by the university, the New York City and State departments of health, and the State medical society. Tuition fellowships amounting to \$90 for each physician were granted through the bureau of cancer control of the State health department.

A 1-week intensive course in the newer aspects of diagnosis and treatment has been started for interested full-time health officers of the State at Roswell Park Memorial Institute. A clinical

refresher course, it is designed to show the work being carried out at the State cancer hospital. It is held from time to time and is usually limited to five physicians.

During the last few years, the Academy of General Practice organized meetings for its members devoted to the subject of cancer. These have been both on the State and county level. This trend is one which the bureau of cancer control encourages whenever possible. The bureau also assists with reimbursing the speakers.

Table 1 shows the distribution of professional cancer education meetings in 1951.

Cancer Reporting

Cancer reporting became mandatory in upstate New York by legislative action on January 1, 1940. In 12 years of reporting, the interest and cooperation of the physicians, of the laboratories, and of the hospitals throughout the State have been excellent. The completeness of cancer reporting compares favorably with that of other reportable diseases in the State. Each year physicians, laboratories, and hospitals report over 19,000 new cancer cases of State residents.

It is realized that collecting morbidity reports should not be an end in itself but that its value should be determined by the use of the reports. On the basis of the reports, a central cancer register has been set up in Albany.

Table 1. Professional cancer education by type of audience—New York State, exclusive of New York City, 1951

Type of audience	Number of meetings	Number of talks	Audience
Postgraduate course (physicians).....	3	37	80
Medical societies.....	11	13	536
Other physician groups.....	27	33	1,410
Hospital staff (physicians).....	17	14	580
Medical students.....	4	4	185
Dentists, dental assistants, hygienists.....	8	8	335
Nurses, student nurses.....	76	73	2,151
Pharmacists.....	2	2	296
Other professional groups.....	3	5	115
Total.....	151	189	5,688

Likewise, cancer rosters are maintained in the local city, county, and district health offices. They have proved valuable aids for follow-up, public health nursing services to cancer patients, and educational activities. The reports also form the groundwork for statistical information appearing in the annual report of the bureau of cancer control, and they make possible annual summaries of the cancer cases for each full-time health officer for his particular area. A summary includes number of cases by age, sex distribution, and most common sites. The summary for total cancer cases reported in upstate New York is also sent to the health officer for comparative purposes. In addition, more detailed statistical studies in cancer incidence, mortality, and survivorship are made.

The trend of incidence and mortality rates from cancer for the last 10 years (fig. 1) shows that incidence of cancer in both sexes is increasing at a more rapid rate than mortality. In fact, the mortality rate for females has gradually declined since 1945. It is noteworthy that while the crude incidence rate for females continues at a level higher than that for males, the crude mortality rate is lower for females since 1948.

Incidence rates according to site are compared in figure 2 for the years 1942-44 and 1949-51. Cancers of the skin and lung-bronchus have shown the most marked increase, and cancer of the stomach a decrease. There has been a marked rise in incidence rates for all sites, from 237.0 new cases per 100,000 population during 1942-44 to 265.3 for the 1949-51 period.

Pathological Diagnostic Service

A pathological diagnostic service is available to any physician requesting it and is of great importance in facilitating early diagnosis and treatment. Tissue diagnosis may be obtained by sending a specimen to the department's division of laboratories and research in Albany or to its branch laboratory in New York City. In addition, such service may be obtained locally at most approved laboratories. Of the 12,050 laboratory specimens examined in 1951 by the laboratories and research division, 1,402 (11.6 percent) were found to be malignant.

Figure 1. Reported crude rates of cancer incidence and mortality in New York State exclusive of New York City for 1942-51. Age-adjusting data and 1951 mortality rates are not available.

One hundred of the laboratories in New York State approved for pathology by the commissioner of health also do cytological examinations. They are scattered throughout the State and serve practicing physicians.

Nursing Services and Training

The need for efficient follow-up of cancer patients, both to evaluate the results of therapy and to maintain contact between physician and patient, is generally recognized. There also exists a widespread need for home-nursing care of patients which is met in many areas by public health nurses. To help provide adequate nursing service to the cancer patient, 2-week courses of intensive didactic and practical training have been under way since 1946 at Roswell Park Memorial Institute. They are offered at least twice a year to all supervisory public health nurses from official and voluntary agencies in

the State as well as to some staff nurses. Nurses in key positions, such as supervisors at cancer clinics, clinical instructors, university educators, and a limited number of consultant nurses from other States have also attended. From 1946 to July 1952, 239 nurses have taken these courses. The University of Buffalo School of Nursing offers similar courses for college credit to their graduate nursing students with instruction by the staff of Roswell Park Memorial Institute. As of July 1952, 54 nurses from the university school of nursing had attended the courses at the institute.

Arrangements can also be made through the State health department for a 4-6 weeks' course in cancer nursing at Memorial Hospital in New York City with college credit from New York University. From March 1949 to July 1952, 30 nurses working upstate have taken this course.

The increasing interest in cancer nursing

services and staff educational programs exhibited by most local health units is attributed to the realization of the local full-time health officer that knowledge and techniques in cancer control keep changing, as in any other field. The nurse must be kept up to date to benefit from her knowledge and practice. To achieve this, there must be continuous in-service training. The two cancer consultant nurses of the bureau of cancer control work closely with the supervising nurses of the local health departments in planning and participating in the in-service training programs. The programs are designed specifically for the staff nurse in the field. The method of in-service training varies from area to area, from 1-day meetings to meetings of several days spread over several months. The training usually consists of lectures, seminars, and group discussions of such topics as etiology, prevention, pathology, and therapy. The content of each program is adapted to the cancer problem within the particular locality and to the interests and needs of the nurses.

Promotion of Tumor Clinics

Tumor clinics and tumor diagnostic clinics have become an essential part of the cancer diagnostic and treatment program. Since late in 1939, when the expanded cancer program of the State health department was launched, the number of clinics in upstate New York increased from 23 to 57, as of July 1, 1952. Twenty-eight receive financial assistance in the form of reimbursement for the services of examining physicians, of a consultant, and for part-time clerical and nursing services. In considering the population distribution in upstate New York, as based on the 1950 census, it was found that only 19.6 percent of the people live more than 25 miles from either a tumor clinic or a tumor diagnostic clinic. One can say, therefore, that 80 percent of the people live within 25 miles of a clinic where they may receive expert advice and treatment.

Since tumor clinics are usually organized by the individual hospital medical groups, their staffing and operation is entirely a local staff matter. The bureau of cancer control is available to help or guide in organization or opera-

tion. The tumor clinic program has the full endorsement and cooperation of the State medical society and the Tumor Clinic Association of the State of New York. Periodically, a representative of the American College of Surgeons visits and inspects the individual clinics.

Aside from the patient aspect of the tumor clinic, one should not overlook the splendid opportunity in the tumor clinic for professional education. With this in mind, whenever promoting the formation of tumor clinics, personnel of the cancer control bureau emphasize the importance of using the clinic for tumor clinic conferences, with house and staff physicians participating, and possibly, a consultant brought in from another area to conduct the conference. The general practitioner is invited and encouraged to attend.

Promotion of Detection Centers

Detection centers are a relatively new procedure in cancer control, having developed within the past decade. Efforts to encourage periodic health examinations have not been too successful, but it is encouraging to note that the public is aware of the value of the detection center type of examination. To be most effective in aiding control of cancer, the examination should be repeated every 6 months. Waiting lists should not be extended beyond 4 to 6 weeks, since delaying appointments longer would defeat the purpose of the examination. It is also important to avoid giving the patient a false sense of security once he has been examined. A person going through a center who is not warned may neglect the early symptoms requiring medical attention which might develop before his next examination.

There were 6 detection centers upstate in 1947. By July 1, 1952, 18 were open. Of these, 17 receive some financial aid from the bureau by way of reimbursement for services of physicians, nurses, and clerical staff. In 1951, 5,254 individuals were examined in detection centers, and positive findings of some form of abnormality were found in 74 percent. Of the pathological conditions found, 24 percent were precancerous and 0.7 percent, malignancies (3).

The cancer detection center program has had

Figure 2. Comparison of the major cancer sites for new cases reported for 1942-44 and 1949-51 in New York State exclusive of New York City. The annual average rates are per 100,000 population.

the approval and cooperation of the State medical society. A few counties have shown an interest in organizing programs for cancer detection in the individual physician's office, but it is too early to evaluate the extent to which they answer the needs of the people.

Roswell Park Memorial Institute

Roswell Park Memorial Institute in Buffalo is a 110-bed cancer hospital operated by the department, and is an essential part of the cancer control program. An \$8 million building program at the institute will bring its bed capacity to 516 beds in 1954 and will expand and improve its research facilities.

The institute has a five-point cancer program of prevention, diagnosis, treatment, research, and education. Patients may be referred for

aid in diagnosis and for consultation and special treatment. In 1951, 2,454 new patients were admitted upon referral from the family physician; in addition, there were 29,187 revisits by former patients (4). Approximately 43 percent of the new patients referred were diagnosed as having malignant conditions.

The educational program at the institute includes instruction of medical, dental, and pharmacy students from Buffalo University, postgraduate instruction in cancer to resident physicians and interested practicing physicians, and training courses for public health supervising nurses. Research is conducted in physics, biophysics, nuclear physics, biology, and genetics.

The institute provides valuable consultation services not only to the practicing physician but to the tumor clinics, aiding them in solving

difficult diagnosis and therapy problems. Since all patients are referred by the practicing physician, Roswell Park Memorial Institute has greatly helped him carry out his responsibility of early diagnosis and adequate treatment for the cancer patient.

Summary

The program of the New York State Department of Health in the eight major fields of cancer control activities was discussed. These are: public education, professional education and training, cancer reporting, pathological diagnostic service, nursing services and training, tumor clinics, detection centers, and maintenance of a State cancer hospital. All of these activities properly integrated are essential for the cancer control program in New York State. These eight basic fields can be used as a framework in setting up a program in other areas,

with modifications to suit the needs and conditions of the individual area. Although the primary responsibility of the cancer patient rests with the individual physician, the responsibility for a comprehensive cancer program rests with the medical profession, the health department, and the cancer society.

State Crippled Children's Programs

Congenital physical defects afflicted one in every five children who received services under State programs for crippled children in 1950, according to a statement issued in September by the Children's Bureau of the Social Security Administration, Federal Security Agency. Reports of State agencies administering such programs showed that 44,000 of the 214,000 crippled children served by the programs during the year were born with some physical defect. The total number of children born with physical defects is unknown, the Children's Bureau stated.

The States vary in the scope of conditions for which they furnish program care. Every State includes all children with handicaps requiring orthopedic or plastic treatment (harelips, cleft palates, clubfeet, deformed bones, serious burns, bone and joint tuberculosis, and poliomyelitis). Nearly all assist children with cerebral palsy and arthritis; more than half the States include children with rheumatic fever and cardiac conditions; and some provide attention for children with epilepsy, congenital syphilis, and sight and hearing handicaps.

Recent advances in cardiac surgery have brought an increasing interest in treatment of children with congenital heart defects, the Children's Bureau said. Because the necessary skills and equipment for such treatment are not available uniformly throughout the country, the Children's Bureau has established a special fund to develop regional heart centers where children can go for treatment if it is not available locally.

Field Treatment of Trachoma in North Vietnam

In 1951, 200,000 persons

were treated by mobile teams organized

by the United States Mutual Security Agency

in cooperation with North Vietnam authorities

By ERWIN BRAFF, M.D., and WARREN WINKLESTEIN, M.D., M.P.H.

TODAY, American public health specialists of all kinds—health officers, sanitary engineers, nurses, laboratory technicians, and health educators—are participating in technical assistance programs being conducted by the Technical Cooperation Administration and the Mutual Security Agency (formerly Economic Cooperation Administration) in many parts of the world. These programs are not only contributing to the welfare of the countries in which they operate, but, through their effect in bolstering the economic and health standards of the participating nations, are aiding in the establishment of stable governments.

This field report from the public health division of the Special Technical and Economic Mission to Cambodia, Laos, and Vietnam was prepared by Erwin Braff, M.D., and Warren Winkelstein, M.D., M.P.H., both of the Public Health Service. The program described was developed under the general direction of Lewis C. Robbins, M.D., M.P.H., of the Public Health Service, chief of the division. Dr. Braff is chief of the trachoma control program and Dr. Winkelstein is regional representative in North Vietnam for the division.

Blockhouses built of adobe bricks, such as the one shown here, or of thatching are located throughout the delta. The villagers in the surrounding area gather in these houses for the night.

Technical assistance in improving health conditions includes a variety of activities. It may take the form of guidance in constructing facilities or in establishing programs. It may involve the training of personnel or the operation of demonstration field projects. The trachoma treatment program presently operating in North Vietnam (Tonkin) is but one of the several public health programs fostered by the Mutual Security Agency's Special Technical and Economic Mission (STEM) to Cambodia, Laos, and Vietnam.

Conditions in North Vietnam

Cambodia, Laos, and Vietnam make up the Associated States of Indochina, a part of the French Union. These countries, particularly Vietnam, have been torn by bitter civil war since 1946. In North Vietnam, one of the three administrative regions of Vietnam, the areas held by the communist-led Viet Minh as of April 1952 comprised about three-fourths of the land area. Essentially all that was held by the French Union forces was the Red River Delta and a narrow coastal strip leading up to the Chinese border (shaded area on map). However, in the delta live approximately 10,000,000 people. The area includes roughly 15 provinces, each province divided into districts, and a district containing as many as 50 villages.

Complicating the situation in North Vietnam is the fact that even within the so-called per-

imeter of control there are many areas which are Viet Minh controlled. Everywhere in the delta stand blockhouses, and military operations frequently destroy the tranquillity of the rice fields. But in spite of these factors, the economy of the area is improving.

Technical aid in Southeast Asia has as one of its primary purposes the strengthening of the democratic bloc of nations. In areas already under strong communist influence and close to Communist borders, such as North Vietnam, it was felt that programs capable of having prompt and widespread effect should receive priority. The term "impact program" is used to designate such efforts. It was hoped that impact programs would reach enough people quickly and effectively to demonstrate that the United States is concerned with human welfare. Communist propaganda has apparently led many Asians to feel that American foreign policy is aimed at underwriting colonialism and exploiting the people and lands of Asia in a power struggle with the Soviet Union. Military aid alone is not enough in view of the vast social problems evident to the common man in Asia and the exploitation of these problems by communist agitation. Thus public health technicians in this area have been faced with prob-

An "infirmier" (nurse) applies aureomycin ophthalmic ointment to a young patient with trachoma.

lems never encountered in conventional practice at home.

Trachoma Prevalence

In August 1950, the public health division of STEM began operations in the Red River Delta of North Vietnam. It has long been known, and was soon apparent to Mission members, that this was a region of intense trachoma prevalence. Casual observations in numerous villages brought forth estimates that as high as 50 percent of the population was suffering from gross eye lesions. At the Ophthalmologic Institute of Hanoi, capital of North Vietnam, hundreds of cases of trachoma, in all stages, were seen daily. In confirmation of these estimates, a study conducted by qualified ophthalmologists of the institute revealed evidence of trachoma in 283 out of 406 boys between the ages of 6 and 24 at an orphanage on the outskirts of Hanoi, an attack rate of 70 percent. Local ophthalmologists and health officials agreed that probably more than 70 percent of the population suffer from active trachoma at some time during their lives.

The facilities for dealing with this problem consisted of the following: The Ophthalmologic

The patient is registering for an eye examination. His name is recorded, and he is given a personal record card.

Institute of Hanoi, which had been established under French auspices, contained about 100 beds and an active out-patient clinic. It was staffed by two fully qualified, European-trained ophthalmologists, several part-time assistants, and a varying number of interns and medical students. The annual (1951) in-patient load was 6,383, and the out-patients numbered 47,567. Of the 15 provincial hospitals existing in 1946, only 3 remained in operation. Only 2 of the other 12 provinces were fortunate enough to have a physician. In addition to these facilities, there were 100 provincial and district dispensaries staffed by "nurses," generally men with 1 to 2 years' nurses training. Trachoma treatment consisted of conjunctival "brushing" and copper-sulfate instillations.

Faced with this situation, local health officers were anxious to develop a treatment program. Reports had raised the hope that aureomycin might be a specific in trachoma treatment. Therefore, under the auspices of STEM and with a grant of aureomycin from a manufacturing firm in the United States, a study was set up at the Ophthalmologic Institute. This study revealed aureomycin to be extremely effective in curing secondary infections and apparently in arresting the early inflammatory stages of the disease. Even advanced cases claimed considerable subjective improvement. Despite the inconclusive nature of these results, regional health officials, as well as mission members, favored the establishment of a mass treatment program using aureomycin ophthalmic ointment.

A group of villagers in North Vietnam have been assembled to be examined for trachoma. Note evidences of trachoma and its late complications.

Of the 12 specimens excluded from the evaluation 11 were unpreserved specimens; the other was a stool preserved in PVA-fixative.

Table 1. Types of specimens distributed to participating laboratories and referees during the parasitological evaluation program

Types of specimens	Total number distributed	Number in official key	Number in key with <i>E. histolytica</i>
Stools in vials:			
Unpreserved-----	55	44	3
In formalin-----	45	45	13
In PVA-fixative-----	4	3	1
Stained fecal smears-----	3	3	0
Stained fecal smears in PVA-fixative-----	3	3	1
Total-----	110	98	18

The 110 specimens were mailed in 11 equal shipments between July 1949 and June 1950. Various postal methods were used in order that the specimens of a given shipment might arrive at the laboratories on approximately the same date. Of 4,950 specimens shipped, only 7 arrived in a damaged condition. The report form which accompanied the specimens gave information on the type and collection of specimen on one side, and on the other provided space for recording the condition of the specimen upon arrival, the examination techniques used by the participating laboratories, and the names of the organisms found. At the bottom of the report was space for the signature of the director and the name of the participating laboratory. Duplicate report forms were provided in order that the laboratories might maintain independent records. (Copies of the form are available from the authors upon request.)

Each participating laboratory and referee was given a code number, known only to the laboratory involved and to certain individuals within the Communicable Disease Center. When the reports were received at CDC, the code number of the laboratory was written on each side of the report. The signature of the director was then detached and put in a separate file to protect the identity of all records.

Official Key to Identification

Portions of the specimens were sent to the three referees on the same day they were distributed to the participating laboratories. In addition, specimens were mailed to a neighboring State and returned to Atlanta for examination by the parasitology laboratories of the Communicable Disease Center. The three referees and CDC agreed on the presence or absence of *E. histolytica* in 91 specimens. In 7 other specimens, two of the referees and CDC reported the presence of *E. histolytica*. Therefore, in 98 specimens out of 110 distributed, the presence or absence of *E. histolytica* was confirmed by at least two referees and CDC. The 12 other specimens were excluded from the evaluation since only one referee and/or CDC reported the presence of *E. histolytica*.

Other organisms were included in the official key to the 98 specimens if at least two of the three referees reported them. If only one referee and/or CDC reported a given organism (exclusive of *E. histolytica*), the organism was placed in the official key in parentheses. In scoring the reports, the participating laboratories were given credit if they found the additional organisms, but they were not penalized for failing to find them. The complete official key to the 98 specimens has been published elsewhere (3).

Scoring of Reports

The official key was used to check the errors and omissions of the laboratories in reporting organisms. The scores of the laboratories were determined on the basis of the number of the 98 specimens examined. Three laboratories, 8, 21, and 30, were scored on the basis of 97, 79, and 74 specimens, respectively. For each specimen, the reporting laboratory received two principal scores, "A" and "B."

"A" Score (*E. histolytica*). In compiling the "A" score, only *E. histolytica* was considered. A unit value was given whenever the presence or absence of *E. histolytica* was reported correctly. The total score of each laboratory was converted to a percentage of the maximum score possible for the number of specimens examined.

Figure 1. Proficiency of participating laboratories in detecting and identifying *E. histolytica* ("A" scores).

"B" Score (all organisms). All organisms, including *E. histolytica*, were considered in determining this score. If the laboratory reported all of the organisms found by two or more referees and did not report any organisms not reported by any referee, it received the maximum score of 10 for the specimen. Misdiagnoses, omissions, and additions of organisms were given numerical values and were subtracted from the maximum possible score for each specimen. The resulting scores were converted to percentages.

All of the information on the specimens (examination procedures, organisms reported, and the scores, as well as the supplementary information mentioned below) was recorded on IBM cards for tabulation.

Supplementary Information

As much information as possible about the participating laboratories was obtained for use in interpreting the results. Information was available from two main sources—a questionnaire distributed during the evaluation program and the records of the laboratory consul-

tation services of the Communicable Disease Center.

The questionnaire on the laboratory examination of stool specimens for parasites requested the participating laboratories to furnish information on the volume of parasitological work, the type and condition of specimens examined, the type and frequency of techniques used, and the technical training of laboratory personnel performing the examinations. Forty-one of the laboratories returned the completed questionnaire. The code numbers of the laboratories were written on the questionnaires in order that they might be filed anonymously after the signatures of the directors had been detached.

Statistical information pertaining to the technician workload and the financial status of the laboratories was obtained from the files of the office of the laboratory consultation services. The information in these files has been collected by CDC staff members or consultants in the course of conducting program reviews of the laboratory facilities of the State departments of health. The information used was collected just prior, during, or immediately following

the period of the evaluation. These program reviews are conducted under the auspices of the respective Federal Security Agency Regional Offices as assignments from the Division of State Grants of the Public Health Service. Not all of the participating laboratories had had program reviews during the specified period. However, information was available on 38 of the participating laboratories.

Identification of *E. histolytica*

The laboratory scores for reporting correctly the presence or absence of *E. histolytica* in the 98 specimens ranged between 59.5 and 99.0 percent (fig. 1). All but 12 of the 42 participating laboratories made a score above 90 percent. Since in this study emphasis was placed upon *E. histolytica*, the "A" scores of the participating laboratories determined the official rank order for the parasitological evaluation (table 2).

There were 18 instances when *E. histolytica* was known to be present in the 98 specimens according to the examination of the referee laboratories. Four of the participating laboratories found all 18, while other laboratories missed from 1 to 16 of these positives. On an average, *E. histolytica* was missed 4.1 times by the laboratories.

In 80 specimens *E. histolytica* was reported absent by the referee laboratories. Six of the participating laboratories did not report any false positive diagnoses of *E. histolytica*; the remaining laboratories reported it to be present in from 1 to 21 of the 80 specimens. On an average, the 42 laboratories added *E. histolytica* 4.4 times when it was known to be absent according to the reports of the referees.

Identification of All Species

In addition to *E. histolytica*, 14 other species of organisms were found in the 98 specimens by the referees and CDC (table 3). Of the 98 specimens, 74 were reported positive by the referees and contained a total of 149 species infections. No organisms were found by the referees in 24 specimens.

As described previously, the "B" scores were obtained by considering all of the organisms re-

ported to be present. The "B" scores of the participating laboratories ranged between 42.0 and 97.1 percent (fig. 2). In 600 instances organisms were reported by the participating laboratories when they were not recorded on the official key. The number of added organisms ranged from 3 to 62, with an average of 14.3 per laboratory.

Figure 2. Proficiency of participating laboratories in detecting and identifying all species of organisms reported to be present by referees ("B" scores).

On 1,355 occasions the participating laboratories missed organisms reported present by two or more referees. The number of missed organisms ranged from 5 to 75, with an average of 32.3 per laboratory. The combined number of additions and omissions for the participating laboratories amounted to 1,955 errors, ranging from 10 to 106. The average was 46.5 per laboratory.

Factors Relating to "A" Scores

Although the scores of certain laboratories might indicate that improvement is needed, these scores furnish no information as to possible underlying reasons for the differences in proficiency. Such factors as type of specimen examined, procedures used, training and experience of the technicians, and financial status of the participating laboratories were analyzed. Whenever statistical significance was found (P approximately equal to or less than .01), it is so stated. Statistical analysis was made diffi-

cult by the small numbers and the incomplete data in some instances.

For the sake of discussion, the laboratories have been divided into three groups according to their *E. histolytica* scores in the official rank order (table 2). The upper group consists of 12 laboratories with scores above 95 percent; the middle group, of 18 laboratories with scores between 90 and 95 percent; and the lower group, of 12 laboratories with scores below 90 percent.

Type of Specimen Examined

The 98 specimens examined by the participating laboratories fall into three general types: (a) unpreserved stools, 44; (b) stools preserved in formalin, 45; and (c) specimens requiring examination from permanently stained fecal smears, 9 (including 3 stained fecal smears and 6 stools preserved in PVA-fixative).

Table 4 presents the "A" scores made on the three types of specimens by the upper, middle, and lower groups of laboratories. There was

Total-----	96	53	149

¹ No organisms found in 24 specimens.

little or no difference between the scores on the unpreserved and the formalinized specimens for each of the three groups. However, all three groups made significantly lower scores with the stained smears.

Number of Tests Performed

Although a few of the laboratories performed routinely only one test on each specimen, the majority varied the number, apparently depending upon the difficulty and the type of the specimen. Including the specimens which were submitted as stained smears, from one to a half-dozen techniques were performed on each specimen, with an average of slightly less than two tests per specimen. On an average, the upper, middle, and lower groups performed, respectively, 185, 166, and 165 tests in the examination of the 44 unpreserved and the 45 formalinized specimens (table 5). No upper group laboratory did less than 100 tests.

Type of Procedures Used

The four major types of procedures used by the laboratories in the examination of the 98 specimens were in order of frequency: temporary wet mounts, concentration techniques, permanent stains, and cultivation (table 6).

All four types of procedures could be used on the unpreserved specimens but not on the other types of specimens distributed. The stained fecal smears and the specimens preserved in PVA-fixative could be examined effectively only from permanently stained preparations. The formalinized specimens could not be cultured. Permanently stained smears could not be prepared as successfully from formalinized as from unpreserved specimens. Nevertheless, the frequency of use of the four major procedures on the unpreserved specimens (temporary mounts, 41.8 percent; concentration techniques, 44.7 percent; permanent stains, 11.1 percent; cultivation, 2.4 percent) does not differ significantly from the frequencies for all specimens (table 6).

Temporary wet mounts employing saline, iodine, and other solutions were used by 41 of the 42 laboratories, and one or more concentration procedures were used by 38 laboratories. Of the various concentration procedures, the zinc sulfate technique was utilized approximately three times as frequently as any of the others (table 6). The brine-flotation technique was used rarely. Sedimentation and the acid-ether techniques (or modifications) ac-

Table 4. Average *E. histolytica* (or "A") scores made in examination of different types of specimens by upper, middle, and lower groups of laboratories in official rank order

Official rank order	Percentage of laboratories in each group performing			Average number tests per laboratory
	100 tests or less	101 to 200 tests	201 tests or more	
Upper group—12 laboratories-----	0	58	42	185
Middle group—18 laboratories-----	17	66	17	166
Lower group—12 laboratories-----	25	50	25	165
All 42 laboratories----	14	60	26	172

¹ Lower group did not report examination of 22 unpreserved and 13 formalinized specimens.

counted for slightly more than one-third of the concentrations performed. Several of the laboratories indicated that they employed the formalin-ether sedimentation technique.

Twenty-one of the laboratories prepared permanently stained smears in the examination of the unpreserved and formalinized specimens. Probably owing to the difficulty of staining formalinized specimens, the procedure was used approximately one-half as frequently on that type of specimen. According to the reports of the laboratories, several procedures were used in preparing the permanently stained smears. The Heidenhain iron-alum hematoxylin technique was used in over 50 percent of the occasions. In 25 percent, the technique was designated simply as a modified Heidenhain procedure. Of the remaining instances, where the modifications were specified, Tompkins and Miller's technique was used 87 times, Goldman's 71, Brown's 66, and Kessel's 21.

Only three laboratories used cultivation in the examination of the unpreserved specimens. The media used were Cleveland and Collier's with or without the addition of streptomycin, and modified Boeck and Drbohlav's egg slant or modified Loeffler's blood serum with fluid overlays.

Table 7 indicates the percentages of labora-

tories in the upper, middle, and lower groups which employed the four major types of procedures routinely or frequently in the examination of the specimens. Since 9 of the specimens could be examined only from permanently stained smears, they have been excluded from this tabulation. Only the 44 unpreserved specimens were considered in determining the frequency of use of permanently stained smears and cultivation since the techniques were not fully applicable to the formalinized specimens.

A large proportion of the laboratories in each of the three groups frequently used temporary wet mounts and concentration procedures. Permanently stained smears and cultivation were used more extensively by the lower group than by the two higher groups. However, although only one laboratory (8 percent) in the upper group used either of these techniques frequently, six (50 percent) used stained smears and one (8 percent) used cultivation as supplementary procedures.

The most common combination of any two procedures was that of wet mounts and concentration techniques. This combination was used by 28 of the laboratories. Only one laboratory in each of the upper two groups employed three procedures routinely, while four laboratories did so in the lower group.

Experience and Training

According to the returned questionnaires, the participating laboratories examine from 100 to 200,000 stool specimens for intestinal parasites each year. The volume of this type of

²Performed on 44 unpreserved specimens.

work can be taken as an indication of the parasitological experience of the technicians. Table 8 presents information on the number of specimens examined by the laboratories in the three "A" score groups. It should be noted that the upper group included the largest percentage of the laboratories examining more than 1,000 specimens each per annum.

The thoroughness of the routine parasitological examinations is also indicative of experience. Ten laboratories in the upper group, eight in the middle group, and six in the lower group, use routinely two or more techniques in the examination of the stool specimens that are received. Since a laboratory receiving only a few specimens a year may employ several procedures on each specimen, a better index of experience is perhaps obtained if the thoroughness of examination and volume of work are combined. Of the laboratories in the upper, middle, and lower groups which examine more than 1,000 specimens each year, a significantly greater number in the upper group use multiple techniques routinely (table 8).

In the questionnaire, the laboratories were requested to give information on the training

of the personnel performing the parasitological examinations. The type of training reported was so varied that it was not possible to analyze all of the information given. However, it is possible to correlate the data in reference to specific training in the laboratory diagnosis of parasitic diseases. Twenty-six of the laboratories reported that a total of 41 individuals examining stool specimens in their laboratories had attended refresher courses in this specific field. Eighty-three percent of the laboratories in the upper group, 65 percent in the middle, and 42 percent in the lower group had individuals who had attended the courses (table 8). The average number of trained persons per laboratory was greatest in the upper group.

Population Served and Workload

In general, the more populous States were represented by the laboratories in the upper group of the "A" scores (table 9). The average population represented by this group was over a million and a half greater than that of either of the lower two groups. Furthermore, rather large proportions of the States represented by the laboratories in the lower two groups had populations of less than a million each.

The number of tests performed by a technician per annum can be considered as indicative of the work load. Information which was available on 37 laboratories is presented in table 9. In the individual laboratories, syphilis serology accounted for 40 to 89 percent of the tests performed, with an over-all average of 71 percent. Although there are inequalities due to the difference in volume of syphilis serology, and to the variety of other tests performed, they tend to average out within the different groups of laboratories. The average number of tests was the lowest in the upper group. In 25 percent of the laboratories in the upper group, the workload was less than 10,000 tests per technician.

Financial Status of the Laboratories

Information on financial status was available on 38 of the participating laboratories. The data indicated a significant trend in the relationship between higher total budgets and the greater proficiency of the laboratories in the upper group (table 10). The average budget

Table 8. Number of laboratories examining over 1,000 stool specimens per annum and percentage of laboratories with personnel trained in laboratory diagnosis of parasitic diseases

for the upper group was over \$280,000 greater than that for either of the other two groups. Fifty percent of the laboratories in this group had annual budgets of more than \$301,000. The average per capita expenditure was almost twice as much for the upper group as for either of the other two groups (table 10). This trend of higher total budgets among laboratories in the upper score groups is significant.

Discussion

The *E. histolytica* scores of the 42 laboratories in the evaluation do not present a normal curve of distribution. Thirty of the laboratories made scores greater than 90 percent. In other words, this evaluation did not succeed in separating the really superior laboratories from the others. The inclusion of more difficult specimens and a greater number of positive *E. histolytica* specimens might have resulted in a better separation of the laboratories. However, 18 of the 98 specimens were positive for *E. histolytica*, which represents almost twice the generally agreed upon incidence of this parasite in the United States. Furthermore, 12 of the specimens distributed were more difficult, but were excluded from the evaluation for lack of agreement by the referees. With the same percentage of positives and the same degree of difficulty, a better separation of the laboratories probably would have been obtained if it had been feasible to include a much greater number of specimens in the evaluation.

Despite the absence of clear-cut separation of the laboratories, it is interesting to observe the relationship between favorable laboratory conditions and the greater proficiency of the laboratories in the upper group of this evaluation. Although statistical significance was not found in many of these relationships, the consistent trends in favor of the more proficient laboratories are worthy of note, and perhaps are suggestive of possible correlations. A discussion of these conditions may be of assistance to laboratories which undertake to improve their proficiency in view of the results of this evaluation.

The importance of performing multiple tests is suggested by the information on the number of tests used by the participating laboratories in their examinations of the evaluation specimens. On the whole, the more successful laboratories performed somewhat greater numbers of tests. Practically all of the laboratories in the upper group performed two or more tests on each specimen received. However, sheer numbers of tests did not appear to insure greater proficiency since one-fourth of the laboratories in the lower group performed more than two tests on each specimen. The selection of appropriate procedures was probably of greater importance.

The laboratories in the upper group placed greatest emphasis upon the wet mounts and concentration techniques and generally used permanently stained smears and cultivation methods only as supplementary procedures. On

the other hand, several of the laboratories in the lower groups made extensive use of a variety of techniques. Theoretically, the greater the variety of procedures performed, the greater should be the number of infections found. But in some instances it appeared as though certain laboratories attempted to compensate for a lack of knowledge of morphological characteristics by performing several techniques, including the more intricate procedures of staining and cultivation.

Although permanently stained smears were

prepared routinely by only one laboratory in the upper group, six others used the technique occasionally. This practice of the more proficient laboratories would tend to emphasize the importance of this type of preparation, particularly as a supplementary procedure for difficult specimens. It probably reflects the good practice of staining the pathogenic protozoa and suspicious organisms in order to maintain a permanent file and to seek collaboration from reference diagnostic centers when desired.

On the whole, the participating laboratories

¹ No information available on 4 laboratories.

made significantly lower scores on those specimens which required examination of stained smears than on the unpreserved and formalin-preserved specimens. This probably indicated unfamiliarity with stained smears. On the other specimens which could be examined by permanently stained smears if desired, only one-half of the laboratories employed the technique. From the questionnaire and other information, it is known that many of the public health laboratories of this country seldom or never use the permanently stained smear in the examination of diagnostic specimens that they receive. Although in some laboratories the technique may be too expensive to be employed routinely on all specimens, it would certainly be advisable for all laboratories to be equipped to prepare permanently stained smears when needed as a supplementary procedure and in the examination of certain types of specimens (for example, those preserved in PVA-fixative).

With current procedures, cultivation for intestinal protozoa is not very applicable to public health laboratories, since they generally receive mailed-in specimens which may be several days old. This probably accounts for the fact that only three participating laboratories used the technique during the evaluation.

Probably of greater importance than technical procedures was the knowledge of the parasites possessed by the individuals who performed the examinations. This is likely to be true more often in parasitology than in other types of laboratory work. The techniques available to the technician do not give objective "yes" or "no" results which can be easily read, such as the presence or absence of hemolysis, a precipitate, acid, or gas. Regardless of the parasitological technique used, the laboratory report of *E. histolytica* must be based on the morphological identification of the organisms recovered. The mere finding of amebas is not sufficient since there are other species that might be recovered by the same technique. Unfortunately, the ability to differentiate the intestinal amebas cannot be learned easily from textbooks. It requires intensive training under a competent parasitologist and months of supervised experience before a person can reliably differentiate the amebas. Furthermore, the diagnostic ability is not a skill that can be

maintained without constant practice. The results of this evaluation tend to confirm the importance of experience and training since in general the laboratories in the upper group of the *E. histolytica* scores perform greater volumes of parasitological work each year and have more individuals who have received special training in this specialty.

As might be expected, there appears to have been a financial relationship with the results of this evaluation. In general, the laboratories in the upper group were significantly better financed than those in the lower two groups. Since the laboratories in this evaluation are dependent upon public funds, it is only natural to find a larger number of the more populous States in the upper group. In addition, this group of laboratories has a per capita expenditure almost double that of each of the lower groups. Therefore, these laboratories apparently can afford to have more technicians for the volume of work performed, use a greater variety of tests routinely, and send more of their technicians to refresher laboratory training courses. Nevertheless, wealth alone is not sufficient as evidenced by the fact that several wealthy laboratories in heavily populated States made relatively poor scores. The results of this evaluation would suggest that in seeking to improve laboratory performance in intestinal parasitology, primary consideration should be given to wise selection of available techniques and the thorough training of technical workers.

Summary

1. Forty-two laboratories participated in the first evaluation of parasitology performed in State and Territorial health laboratories. The study involved the examination of 98 stool specimens distributed by the Communicable Disease Center as unpreserved specimens (44), formalized specimens (45), stained fecal smears (6), and specimens preserved in PVA-fixative (3).

2. The scores made by the laboratories in determining the presence or absence of *E. histolytica* ranged between 59.5 and 99.0 percent, with all but 12 of the laboratories making scores above 90.0 percent. The laboratories were also scored in reference to reporting other intestinal

parasites determined to be present by referee laboratories.

3. In order to furnish more information which might serve as a basis for eliminating deficiencies, the relative proficiency of the laboratories is discussed in relationship to the type of specimens examined, the technical procedures used, the training and experience of the technicians, and the financial status of the laboratories.

ACKNOWLEDGMENTS

The authors express their appreciation to Dr. Elberton Tiffany, laboratory consultation services of the Communicable Disease Center, for supplying informa-

tion on the participating laboratories from his program review files; to Myron Willis of the statistics section for his assistance in the analysis of the data; and to Sadie Johnson of the parasitology and mycology section for technical assistance in the preparation of the evaluation specimens.

Manpower Policy

To help meet the problem of critical manpower shortages, the Office of Defense Mobilization in September outlined an information and guidance program for employers, educational institutions, professional associations, and Government agencies concerned with the training and utilization of scientists and engineers.

The Office of Defense Mobilization statement was published as ODM Defense Manpower Policy No. 8 and appeared in the Federal Register on September 6, 1952. The statement included a discussion of the problem as well as a series of recommendations which are applicable to professional and technical personnel employed by public health agencies—physicians, dentists, and nurses as well as scientists and engineers. Employers are urged to:

Review and reevaluate the duties, responsibilities, training, and experience requirements of technical positions to determine the minimum qualification levels required for each position, and to develop research leaders and administrators;

Cooperate with educational institutions, in the development of on- and off-the-job training programs for technical personnel and in the selection and training of subprofessional personnel to relieve scientists and engineers of routine duties;

Assure salaries that are commensurate with the skills and contributions of professional technicians;

Consult with public employment offices to avoid recruitment activities disruptive to high-urgency defense work, and to cooperate with employer associations in implementing industry-wide measures to alleviate the effects of technical person-

nel shortages and in expanding scholarship programs for promising students who otherwise might be unable to complete their education;

Provide comprehensive employment information to local Selective Service boards, and appropriate military authorities, for their use in classification of registered employees engaged in essential scientific activities and in determining eligibility for delay in recall to active duty for essential employees so subject;

Utilize fully women and members of minorities with scientific training;

Cooperate with public and private agencies in determining current and long-range requirements and resources of scientists and engineers and in developing relevant information regarding employment, such as salaries, hours, mobility, and working conditions.

Usefulness of Communicable Disease Reports

By IDA L. SHERMAN, M.S., and ALEXANDER D. LANGMUIR, M.D., M.P.H.

IN ANY discussion of routine morbidity reporting there is always the casual observer of morbidity data who proclaims, "I don't know anything about reporting procedures, but the data are no good!" The question may be raised, "No good for what?"

Routine morbidity reporting of communicable diseases has been maligned by the perfectionist who calls for the same precision in these data as in those derived from an experiment in which the variables can be controlled. Even with the problem of bias removed in an experiment and despite the investigator's most careful efforts, he will get variations in his results that, for want of more precise knowledge, he labels experimental error. And with everything under rigid control, the data are still imperfect.

Every measurement is an imperfect datum, and every investigator has the problem of judging the extent of error and of keeping the interpretation within these limits. Interpretation of morbidity data must be guided by use of collateral evidence obtained from field investigations and epidemiological studies.

Our system of notification of individual case reports is a haphazard complex of interdependence, cooperation, and good will among physicians, nurses, county and State health officers, school teachers, sanitarians, laboratory

technicians, secretaries, and clerks. It is a rambling system with variations as numerous as the individual diseases for which reports are requested, and as numerous as the interests and individual traits of the administrative health officers, epidemiologists, and statisticians in the 48 States and the several Federal agencies concerned with the data. It is a system that depends on persuasion, education, and, in some instances, alarm. And the variables cannot be eliminated by regimentation and fiat.

In spite of the inaccuracies of the resultant data, morbidity reports are indispensable for immediate recognition of a disease situation which requires public health action. They are time-tested in determining areas and trends of disease; and they are important in administrative planning of long-range programs and in providing the raw material for epidemiological research. These broad objectives of the notifiable disease system, while well known, are often not considered adequately.

Essential for Public Health Action

The notification system is essential for the control of the rare and serious disease. Immediate knowledge of a case is needed for the epidemiological follow-up that will protect the community. For such diseases as smallpox and plague, a report of when and where a particular case develops is of paramount importance. And the system has proved effective. No community has been caught wholly unaware in recent years in an outbreak of these rare diseases. But the possibility of an outbreak cannot be disregarded.

The diseases listed in the international quarantine regulations, while rare in this country,

Mrs. Sherman is assistant chief of the statistics section and Dr. Langmuir is chief of the epidemiology branch of the Communicable Disease Center, Public Health Service, Atlanta, Ga. This paper was presented June 17 at the 2d Conference on Public Health Statistics, School of Public Health of the University of Michigan, Ann Arbor.

are problems of concern throughout the world, especially since modern transportation facilities provide an opportunity for transmission of disease from one country to another in a few hours or days. According to the 6-month report issued by the Public Health Service Division of Foreign Quarantine on world prevalence of quarantinable diseases for the period ended December 31, 1951, plague is suspected in all South American, African, and Asian ports and in the Mediterranean ports of Spain, France, Greece, Italy, Malta, and Turkey. All countries are considered potentially infected with smallpox with the exception of Canada, the islands of St. Pierre and Miquelon, Iceland, Greenland, the west coast of Lower California, Cuba and the Bahama Islands, the Canal Zone, the Bermuda Islands, Aruba, Curacao, and ports under the control of the United States. Cholera is reported by Burma, India, and East Pakistan. Yellow fever is reported in Africa, jungle yellow fever in South American areas, and epidemic typhus in Afghanistan, Ethiopia, Yugoslavia, and Ecuador, with some few cases reported from other areas in South America and the Near East.

The protection of our communities depends on immediate notification of the occurrence of these diseases so that, once a diagnosis is made, proper measures may be instituted. The mass immunization against smallpox in New York City a few years ago is a case in point (?). For 20 years the city had not had an outbreak, and universal vaccination had been a standard recommendation for much longer. But in March 1947, a merchant living in Mexico, who traveled to New York City by bus, fell ill, was admitted to a city hospital, and died within a few days. The diagnosis was smallpox. Twelve cases developed from the initial case, two ending in death. The duration of immunity induced by vaccination varies considerably so that a vaccinated community may not be presumed to be an immune one. In this outbreak, the merchant had been successfully vaccinated in childhood. The introduction of smallpox into a community such as New York City could engender a sizable epidemic. As a result of prompt notification of the smallpox outbreak and efficient epidemiological follow-up, the decision was reached to undertake immunization

or re-immunization of the New York City population. In addition the Public Health Service traced the route of the bus to determine whether additional foci of infection had developed in other States. Certainly, individual case reports at such a time are indispensable.

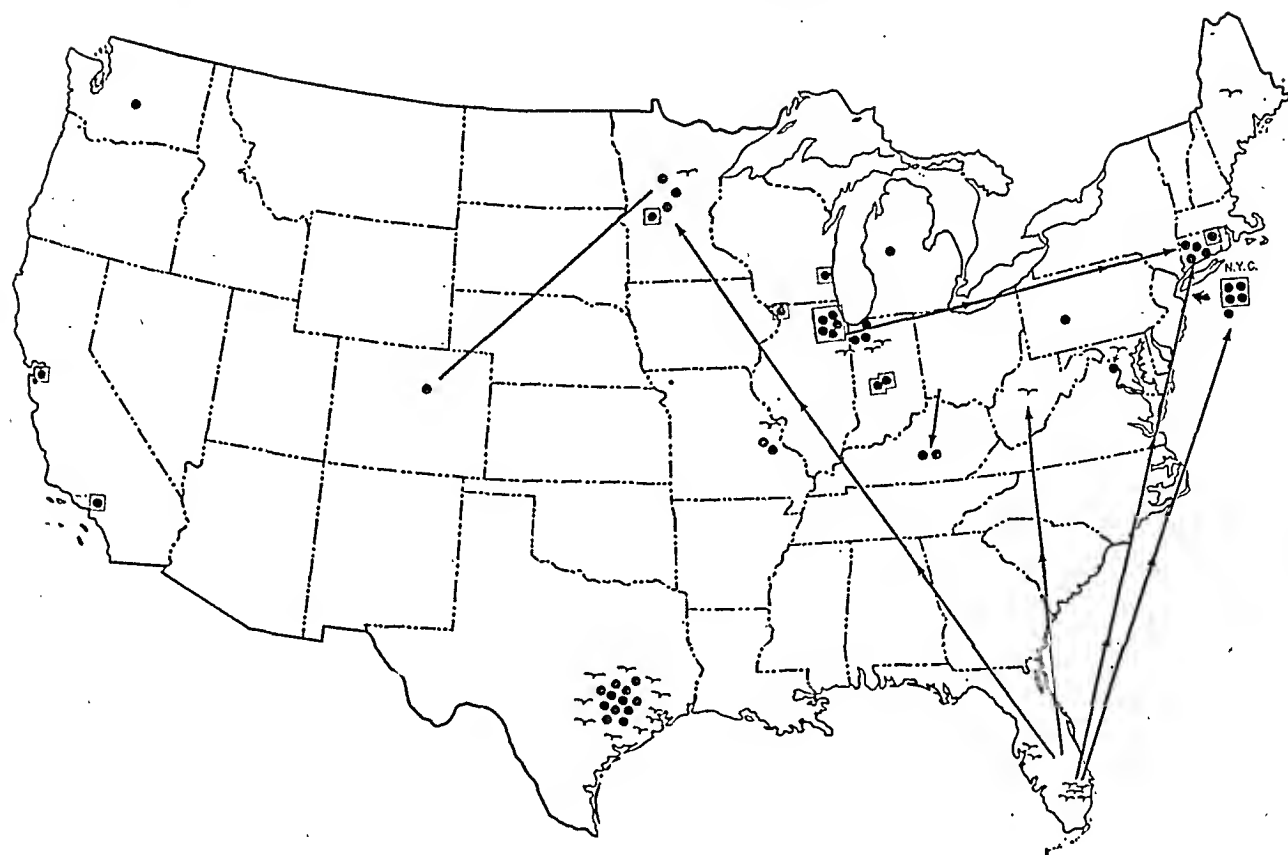

Leprosy has world-wide distribution, and there are areas in the United States where the disease has been recognized over a period of years. The greatest number of persons with leprosy admitted to the National Leprosarium at Carville, La., resided in Louisiana, Texas, and California at the time of admission. In those areas, the physicians frequently consult local public health authorities for diagnosis and advice on subsequent treatment or isolation. Knowledge of these cases is gained from two sources: notification to public health authorities by the physician and subsequent systematic clinical study of contacts. The control of this disease depends on continued notifications to health officials of individual cases as they are recognized.

Location of Disease Areas

For diseases of relatively low incidence, reported case data provide information for location of pinpoint areas where further epidemiological understanding of the disease may be gained through field investigation. During the thirties, outbreaks of psittacosis, transmitted for the most part by psittacine, gallinaceous, and columbian birds, resulted in quarantine regulations affecting the importation and transportation of such birds as parrots and parakeets. After the disease incidence had been low for many years, the quarantine regulations were eased in December 1951 permitting freer transportation of psittacine birds from State to State. The change in regulations removed many of the "black market" aspects of traffic in these birds, and epidemiological follow-up was facilitated.

Early in January 1952, the National Institutes of Health of the Public Health Service reported the virus had been isolated from a bird that had died in Florida. Then followed reports of human cases from different parts of the country. What did the widely scattered and apparently sporadic cases of psittacosis

Figure 1. Reported human psittacosis cases in relation to avian source, 1952.

mean, if anything? By piecing together the evidence gained from the description of psittacosis cases published as epidemic reports with some of the early findings made by an epidemic intelligence officer of the Public Health Service, the data became meaningful. Figure 1 indicates schematically how birds transported to Connecticut and to Minnesota from an infected Florida aviary were incriminated in human cases of psittacosis. A case developed in a Colorado visitor to the Minnesota family owning the infected parakeet. Birds grown locally in Chicago were incriminated in Chicago cases and in a Connecticut case. A Washington, D. C., case was attributed to a bird grown in Maryland where another infected bird was discovered. The outbreak in Texas was among turkey pickers, and the Kentucky cases were attributed to infected birds acquired in "neighboring States." Further epidemiological follow-up revealed the presence of infected birds with no associated human cases, and some additional human cases were uncovered which could not be traced to specific sources of infection.

Until about 1930, Rocky Mountain spotted fever was recognized only in the western portion of the United States. Since that time, increasing numbers of cases have been reported from the eastern portion of the United States, and entomologists, particularly, have been concerned with the distribution and natural history of ticks that carry the rickettsiae. Figure 2 shows the distribution of reported cases of Rocky Mountain spotted fever, by county, for the years 1945-50. The concentration of the disease along the eastern seaboard is apparent and the value of a simple spot map of reported cases is obvious. Entomologists and epidemiologists find such maps useful in selecting areas for study.

Murine typhus fever has been a disease of public health importance in this country for almost two decades. It has some characteristics similar to Rocky Mountain spotted fever, and there is possibility of error in differentiating the two diseases. But the differential diagnosis is aided by recognition of the distinct differences in their geographic distribution. Rocky

Mountain spotted fever is concentrated along the eastern seaboard and western sections of the country. Typhus, however, is concentrated in the Gulf States. Although there may be errors in the reports of the two diseases, especially in the overlapping fringe areas, the salient fact of two distinct areas of major concentration is provided by reported morbidity data.

From 1932 to 1940, murine typhus cases for the United States and for the 10 southern States from which the great majority was reported showed a general upward trend which may be attributed to better recognition of the disease rather than to increased incidence.

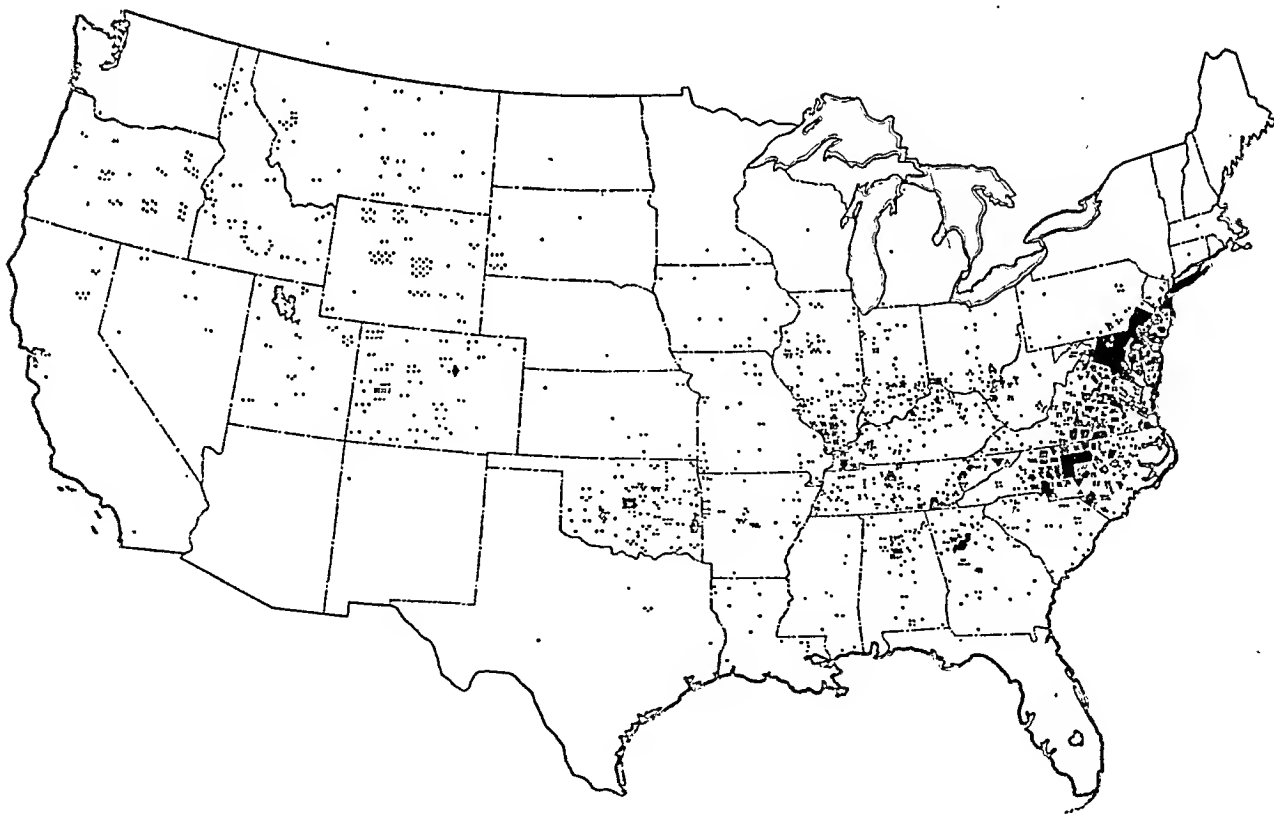

After 1940 there was a sharp rise in the number of cases reported in the United States. Typhus distribution in 1944 suggested increased incidence in the endemic area rather than a marked extension of the disease into new areas. In corroboration, during this period larger numbers of typhus cases were recognized in the teaching hospitals of the endemic area. And in field studies, cases confirmed by laboratories exceeded those reported to local health authori-

ties. The number of reported cases began declining in 1946, and these figures are in line with field evidence. The decline since 1948, however, is difficult to interpret since, with the introduction and wide use of antibiotics, recognition of the disease has been obscured, but the 1951 distribution of residual murine typhus is in the same general areas as during the period of its highest incidence (fig. 3).

Determination of Trends

Diphtheria is such an old story that we look at the declining rate of incidence with a feeling of satisfaction and complacency. Looking at the reported case data, we find that the morbidity rate for the United States dropped from 30.8 per 100,000 in 1935 to a rate of 2.6 in 1951. State rates for 1951 show that this is not the complete story on the reduction of the disease in the United States (fig. 4). Although the over-all rate was 2.6, a group of southern and western States had rates twice this figure. Whether these rates reflect differences in reporting procedures, immunization practices,

Figure 2. Rocky Mountain spotted fever cases, 1945-50.

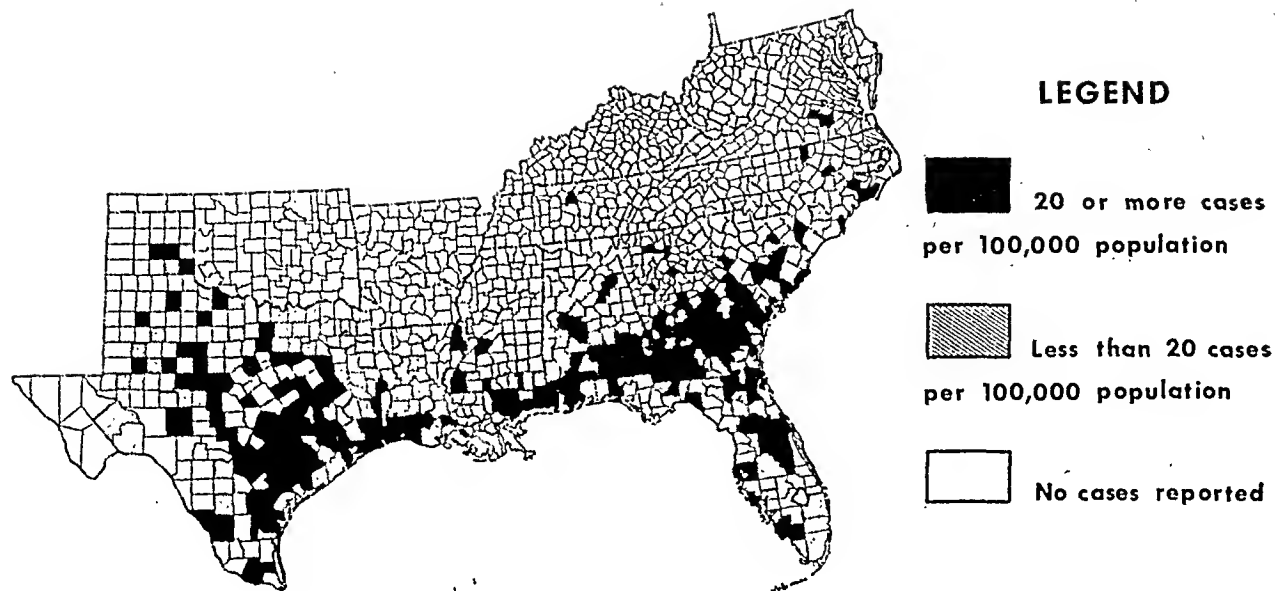

Figure 3. Reported cases of murine typhus in south-eastern United States. Above: Reported murine typhus cases for 1944 (source: cases, Public Health Service; populations, Bureau of the Census — linear intercensal interpolations). Right: Reported murine typhus cases for 1951 (provisional data).

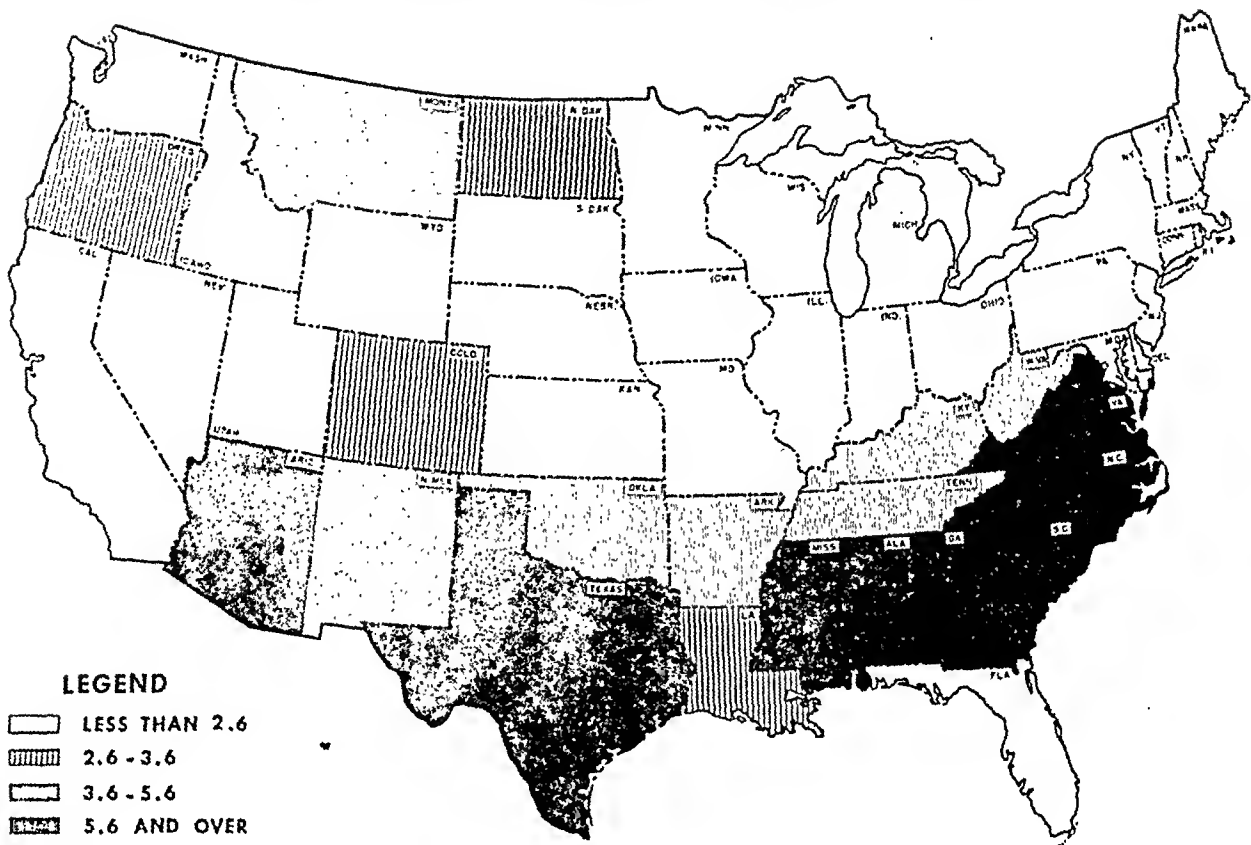

population differences, or peculiarities of various strains of diphtheria is a problem for investigation, but specific morbidity rates enable recognition of a problem and provide the point of departure. The occurrence of diphtheria challenges our health services to locate and eliminate the residue of diphtheria in this country.

In England and Wales, the diphtheria morbidity rate in the 1930's was well over 100 cases per 100,000. In 1940, the English (5) began an intensive immunization program with the goal of immunizing at least 75 percent of the children before they reached their first birthday. A dramatic drop in reported cases followed (fig. 5). From 1944, the English have been able to

show two sets of data, original, or preliminary, and final notifications. The latter include corrections resulting from amendments of diagnosis made either by notifying practitioners or by the infectious disease hospitals. Conclusions based on either set of data indicate that incidence of the disease is reaching a low point and that within the short span of 10 years rapid progress has been made toward its eventual eradication. In fact, the British in the March 1952 issue of their *Monthly Bulletin of the Ministry of Health and the Public Health Laboratory Service* state, "the situation is now being reached . . . where the eradication of diphtheria as an indigenous disease in this

Figure 4. Reported diphtheria cases per 100,000, 1951.

country (England and Wales) can be foreseen as a very real possibility within the next few years, providing there is no slackening in the immunization efforts."

Programs and Research

Measles, in contrast to diphtheria, has not shown a downward trend, and we have just gone through one of the greatest epidemics in the history of the Nation. Why should measles be reported? The question is raised over and over again, and invariably the point is made that there are no control measures for this universal childhood disease. Nevertheless, the use of gamma globulin may minimize or defer the disease in the very young, among whom the great proportion of measles deaths occur. In the United States, among children under 5 years of age, measles accounted for 612 deaths in 1949 and for 7,579 deaths from 1940-49. Two-thirds of the deaths from measles occur in children less than 5 years of age. In a well-ordered health jurisdiction, individual case reports of measles enable follow-up for administration of gamma

globulin to young children who have been exposed. Even though measles is under-reported, the data are useful for recognizing epidemic years during which the hazard to young children should be given special attention.

Epidemiologists and mathematicians have postulated various theories during the past 100 years to explain the dynamics of the spread of diseases. Measles is a universal disease, is easily diagnosed, and presumably is caused by a virus that has reached an extraordinarily stable balance with the human race. Measles data have been useful in the study of epidemics and provide a tool for development of mathematical models of crowd infections which may yield an insight into the dynamics of other infectious diseases (3, 4).

There have been a few objections to notification of poliomyelitis based on the same argument that there are no effective control measures. However, if poliomyelitis were removed from the list of reportable diseases in all States, an informal reporting system would develop overnight. Newspapers, teachers, various business enterprises, hospitals, nurses organizations,

and other agencies would collect, pool, and exchange information on the occurrence of the disease, not because these agencies have control measures which they could institute, but because poliomyelitis is a disease of both local and national interest, and that interest will be satisfied with or without an orderly reporting system.

Reported case data on poliomyelitis are essential for determining areas for current field investigations. The National Foundation for Infantile Paralysis in its extensive program of using gamma globulin as a prophylactic agent is depending upon the established reporting system to pinpoint areas in which to conduct its studies. Study of the frequency of occurrence of reported cases for past years by geographic locations, by urban-rural classification, by age, by sex, by population-size groups, by date of onset, by race, and by other categories have all been valuable; and other aspects of the frequencies and distribution of the reported cases are now being examined in an attempt to gain further insight into the behavior of this disease.

For some diseases of poorly defined etiology, it is known in advance that the reported case data will be of no value in appraising the extent of a specific disease problem, but the reported data may lead to a better definition of the components of the disease complex. For years, the term infectious encephalitis has served as a means for the collection of information on a variety of symptomatic conditions. Although heterogeneous, these data have been a starting point for investigation in one area and another. Thus, in the western States, the arthropod-borne encephalitides form an important portion of these data, and in these States there has been increased field study of the epidemiology of viral encephalitides and the ecology of possible vectors, especially in their relationship to the development of irrigated areas and water impoundment projects. On the other hand, in other sections of the country, study of the data has led to the recognition of quite different etiological agents (1). In these sections the reported data reflect almost entirely encephalitic conditions following attacks of measles, mumps, influenza, and other diseases. The case report is essential for the

Figure 5. Reported diphtheria cases per 100,000 population, United States and England and Wales, 1935-51.

epidemiological follow-up of the individual case of encephalitis that is needed for long-range study of this complex disease entity. Recent study of the reported data has led to recommendations for revisions and improvement in the international statistical classification of infectious encephalitis reports.

Collateral Evidence Useful

Sometimes morbidity data have been patently in error, and, in the instance of reported malaria data, the error was vividly demonstrated by procedural changes instituted by one State on the advice and suggestion of epidemiologists who suspected a disparity between the number of cases reported and the actual incidence of the disease. The evidence gathered by epidemiologists and other field workers during the past two decades provides the means for an orderly interpretation of the reported data.

During the thirties, malaria was highly endemic in much of the South, and surveys conducted in malarious areas during that period showed parasite rates of up to 50 percent in children, but the number of cases reported was only a small fraction of those indicated by these rates of parasitism (2). Malaria during that decade was clearly under-reported. From about 1938 to 1943, laboratory evidence indicated that the disease declined much more rapidly than shown by the reported figures, and from 1943 to 1947, while malaria was decreas-

ing rapidly in States where eradication programs were in progress, other areas of the country showed an increase resulting from importation of malaria by veterans of World War II.

The reported morbidity figures for 1947 indicate a precipitous decline, and while it would be encouraging to explain the recent drop on the basis of effective malaria control measures, the sequence of events in Mississippi suggests that changes in reporting procedures are a more likely explanation for the accelerated decline. Figure 6 shows the annual reported incidence of malaria in Mississippi from 1940 through 1950. Prior to 1946, the physician's case report in Mississippi, as in some other States, permitted reporting of total number of cases by disease, but not by individual case report. On January 1, 1947, this form was replaced by an individual case report. The decrease in the number of reported cases of malaria is extraordinary—a drop from 881.2 to 44.0 per 100,000 population. A year later in that State a procedure was instituted for field investigations to enable individual appraisal of diagnosis of reported malaria cases, and a second notable reduction in the annual incidence rate resulted—from 44.0 to 5.8 per 100,000. Texas is the only remaining traditionally malarious State whose reporting system does not require identification of the patient in reported malaria cases, and there is no question that malaria is grossly over-reported in that State.

In 1950 field evidence and reported cases pointed to a very low level of malaria in the United States. However, in the spring of 1951 many cases were reported by distinctly non-malarious States such as Colorado, Massachusetts, Michigan, Minnesota, Oregon, and Wisconsin. Epidemiological follow-up indicated that a new problem has been introduced into the national malaria picture. The increased number of malaria cases represented importation of malaria by veterans returning from the Far East. Thus, some changes in reported data may be readily explained by alteration in reporting procedures; in other more important instances, changes in reported data may indicate new and authentic disease problems in areas where they did not exist.

Inherent in the system of reporting diseases are numerous flaws, such as over-reporting,

Figure 6. Annual reported incidence of malaria in Mississippi, 1940–50.

under-reporting, incomplete reports, incomplete coverage, and misdiagnosis, which may result from such factors as the attitude of the private physician toward reporting, incomplete etiological definition of reportable disease entities, variation in clinical diagnosis according to local experience with infectious diseases, variation in follow-up and verification of physicians' reports, variation in use and verification of supplementary reports—school and public health nurses' reports, laboratory reports—and variations in laboratory procedures and the criteria selected for querying physicians for case reports (6). Some of the defects may be eliminated gradually through a study of the particular disease in specific areas, but other flaws will probably always remain. Because of these imperfections, errors may be made in interpreting case reports unless they are supplemented by data available from hospitals, military records, medical insurance plans, laboratory and epidemiological investigations, and study of mortality, ecological and demographic data. However, the valuable inferences afforded by analyses of morbidity data are lost to

those who would first pursue the will-of-the-wisp of complete and accurate reports as a sine qua non for serious consideration of reported data on acute communicable diseases.

The use of morbidity data in long-range studies and in administrative planning requires finesse and patience. But along with shoe-leather epidemiology, case reports are essential for the control of communicable diseases.

Shipment of Animal Disease Organisms

Recent instances of illegal movement of animal disease organisms and vectors in interstate commerce have prompted the U. S. Department of Agriculture to warn that "no organisms or vectors shall be imported into the United States or transported from one State or Territory or the District of Columbia to another State or Territory without a permit issued by the Secretary and in compliance with the terms thereof." These terms specify that such shipments must serve the public interest, with ample safeguards provided to protect against the further dissemination of such agents.

Conditions under which restricted organisms and vectors can be moved by permit are explained in the Department's Bureau of Animal Industry Order 381, Part 122, entitled "Rules and Regulations Relating to Viruses, Serums, Toxins, and Analogous Products, and to Certain Organisms and Vectors." All laboratories, research institutions, and others dealing with animal disease organisms and vectors are requested to comply with this order.

Applications for permits shall be made in advance of shipment and each permit shall specify the name and address of the consignee, the true name and character of each of the organisms or vectors involved, and the use to which each will be put. Further information and applications for permits may be obtained from the Bureau of Animal Industry, U. S. Department of Agriculture, Washington 25, D. C.

New Structure of Nursing Organizations

ALMOST 10 years of effort by nurses to simplify and improve the structure of their professional associations culminated last June when more than 6,000 nurses at the 1952 Biennial Nursing Convention voted to consolidate their organizations into two major national groups. Of the five national professional nursing organizations existing in 1952, only one—the group representing industrial nurses—remained outside the new structural plan.

The first national nursing organization was founded in 1893; by 1942 there were six. During World War II and the postwar years, these organizations were coordinated first through the National Nursing Council for War Service and later through a joint board of the six organizations. Considerable effort was required for the coordination of their activities in order to prevent duplications and gaps in services. Moreover, members of related professions and the general public were confused as to the respective functions of the organizations. The nursing profession soon recognized that reorganization was in order and set about finding a new structure.

In 1944 the boards of the American Nurses' Association, the National League of Nursing Education, and the National Organization for Public Health Nursing voted to make a survey of the "organization, structure, administration, functions and facilities" of their groups "to determine whether a more effective means could be found to promote and carry forward the strongest possible program for professional nursing and nurses." The Association of Collegiate Schools of Nursing and the National Association of Colored Graduate Nurses joined

in the study during 1945. A formal study and report were made in 1946 by a firm employed for the purpose. From that time until 1952, nurses everywhere, through their local, State, and national committees, worked at designing a new structure for the organization of their profession.

A plan for a single, all-purpose association had some proponents, but the establishment of such an organization presented problems. Non-nurse participation in organizations was recognized as desirable. Certain functions, such as those relating to the setting of standards, however, were considered to be the prerogative of an all-nurse association, and the International Council of Nurses requires that its national constituents be comprised solely of nurse members. Consequently, a plan for two organizations evolved. One, much like the existing American Nurses' Association, would have nurse members only; the other, to be called the National League for Nursing, would have both nurses and other persons as individual members as well as agency and institutional members. The first would be concerned primarily with the individual nurse and her professional welfare and standards; the second, with community nursing services and education to prepare nurses for these services.

At the Biennial Convention of 1952, the National League of Nursing Education, the National Organization for Public Health Nursing, and the Association of Collegiate Schools of Nursing approved an action disbanding their organizations and combining most of their former functions under the new National League for Nursing. Also at this convention, changes were made in the bylaws of the American Nurses' Association, and a means for cooperation between the altered American Nurses' Association and the National League

This summary was prepared by the office of the Chief Nurse Officer, Public Health Service.

for Nursing was formulated. The National Association of Colored Graduate Nurses had gone out of existence several months previously and its functions assimilated in other organizations. The American Association of Industrial Nurses voted not to disband. At present, then, there are three national nursing organizations.

American Nurses' Association

The following are the major activities to be carried on by the American Nurses' Association:

1. Define qualifications for nurse practice in the various occupational groups and for specialities within those groups.

2. Recommend standards for nurse practice in such fields as public health, industrial hygiene, nursing education, private practice, and nursing administration.

3. Promote legislation and speak for nurses on legislative action concerning general health and welfare programs.

4. Take periodic inventories of the Nation's nurse resources.

5. Promote and protect the general welfare (economic, professional, and social) of nurses.

6. Provide professional counseling service regarding employment to individual nurses and to their employers.

7. Act as spokesman for nurses with the public and with official groups (professional, governmental) on a State, national, or international basis.

8. Serve as official representative of American nurses in the International Council of Nurses.

Four sections of the original American Nurses' Association are continued—general duty, private duty, institutional nursing service administrators, and industrial nurses. Three new sections have been added—public health nurses, educators, and special groups, which include nurses who do not come under any other section, such as office nurses and nurse anesthetists. State organizations will be similar to the national organization, and sections will send representatives proportional in number to their membership to the American Nurses' Association House of Delegates, the official voting body which meets every 2 years.

The *American Journal of Nursing* will continue as the official organ of the American Nurses' Association.

National League for Nursing

Nurses and other citizens, both as individuals and representatives of community, health, and educational agencies, are members of the new National League for Nursing. This organization will:

1. Work with allied professions and other interested groups to help communities to meet their nursing needs.

2. Promote the organization and improvement of nursing services in communities, including defense areas where services are often woefully inadequate.

3. Study the kind of education nurses need to give good nursing service.

4. Promote the improvement of educational programs in nursing, and provide accreditation of such programs.

5. Give advisory service to community nursing agencies and counseling service to colleges, universities, and communities regarding the establishment of educational programs in nursing.

6. Interest young people in choosing nursing as a career; test and guide those who are interested so that the ones best suited are selected.

The league has two divisions—nursing services and nursing education—each of which has two departments. Public health nursing and hospital nursing are the departments of the first division; baccalaureate and higher degree programs and diploma and associate degree programs are in the second division.

The committees and services in the National League for Nursing include: Committee on Careers in Nursing, which is promoting the recruitment of student nurses; National Committee for the Improvement of Nursing Services; Committee on Nursing in Medical Care Plans; Joint Committee on Practical Nurses and Auxiliary Workers in Nursing Services; National Nursing Accrediting Service (for nursing schools); Advisory Nursing Service for Orthopedics and Poliomyelitis; and Tuberculosis Advisory Nursing Service.

Eligible for individual membership in the league are registered nurses in all fields of nursing; members of allied professions, such as physicians, hospital administrators, public health administrators, and educators; members of boards and committees concerned with nursing; members of boards and staffs of hospitals and public health agencies which have nursing service programs; and others interested in standards for community nursing service and nursing education. Among those eligible for agency membership are visiting nurse associations; public health nursing services in health departments, schools, and other community agencies; nursing services in industries, hospitals, and other institutions; and both basic and advanced nursing schools.

State leagues for nursing are now being formed all over the country. In general, they have the same divisions, departments, and committees as the National League. Individual members join the national organization through the State organization if such exists. Agency members join the national organization directly. Non-nurse members are entitled to membership on boards and committees and are eligible for election to all offices except those of president and first vice president. Individual members join the department of their choice and vote as members of that department for their own and general officers. State leagues may have district or local branches.

Official Publications

Nursing Outlook, which will begin publication sometime next year, will be the official organ of the National League for Nursing. This, the *American Journal of Nursing*, and the new journal *Nursing Research*, which first appeared in June 1952, will comprise the official journals of the new professional organizations. *Nursing Outlook* will absorb *Public Health Nursing*, the journal previously published by the National Organization for Public Health Nursing.

The American Nurses' Association has memberships approximating 180,000. The National League for Nursing has more than 20,000 individual members transferred from other organizations and is gaining membership daily. Those who joined before September 30, 1952, are charter members of the new organization. Most nurse members of the National League for Nursing will probably also be members of the American Nurses' Association. Membership in the league will provide additional opportunity for community service.

The president of the American Nurses' Association elected at the Biennial Convention in 1952 is Elizabeth Porter, and the executive secretary is Ella Best. The president of the National League for Nursing is Ruth Sleeper, and the general director is Anna Fillmore. The address of the headquarters of both organizations is 2 Park Avenue, New York City.

Yellow Fever Vaccine Production

Yellow fever vaccine, produced exclusively by the Public Health Service since 1942 in order to meet emergency wartime needs, will be manufactured in the future by the National Drug Company of Philadelphia, the Public Health Service announced jointly with the Armed Services Medical Procurement Agency in October.

This step, following conferences with many of the major pharmaceutical houses in the United States, is in accordance with Public Health Service policy of withdrawing from the manufacture of biological products in favor of the pharmaceutical industry when large-scale production becomes feasible.

Manufacture of the vaccine by the private firm does not alter the regulations governing distribution. All eligible consumers now receiving the vaccine may continue to do so.

Patients in Mental Institutions, 1949

This report presents statistics on patients in 199 State, 49 county, 1 city, and 225 private hospitals for mental disease; 16 psychopathic hospitals; 111 general hospitals with psychiatric facilities; and 99 public and 125 private institutions for mental defectives and epileptics. It is based on the twenty-fourth Annual Census of Patients in Mental Institutions, the third such census to be conducted by the National Institute of Mental Health.

The data, based on schedules prepared by these hospitals and institutions, consist of both a bookkeeping account of the flow of patients into and out of the hospitals and institutions and statistics on certain characteristics of first admissions and discharges, overcrowding, personnel, and expenditures.

It also contains discussions of the scope and method of the survey and the classification of reporting units, a definition of terms used, and the limitations of the data presented. There is also a brief historical review of data for the period 1940 through 1949 concerning resident patients, first and all admissions, discharges, and deaths in mental hospitals and institutions.

Health Services in the Structure of State Government, 1950

Part I—Administrative Provisions for State Health Services

All State governments consider public health one of their major functions. The States differ, however, in the way they provide serv-

ices. This publication brings together information regarding health services currently provided by State governments and differences in their public health organizations, methods of administration, scope of activities, policies, and resources.

This is the fourth edition of bulletin 184, containing data on State health organization and administration, each State being surveyed every 10 years. For the 1950 edition, the survey was limited to activity by State governments. No information was sought regarding local services. Therefore, the study does not present a picture of the total services received by the public, but rather it describes the manner in which the participating State agencies function in providing—either directly or through some other organization—health services for which they are responsible. The study constitutes the most complete source of information available on State health organizations.

The entire report is being published in four parts, all carrying the same main title. The second, third, and fourth parts, which will be published later, are subtitled: II—General Services and Construction of Facilities for State Health Programs; III—Personal Health Services Provided by State Government; and IV—Environmental Health and Safety Services Provided by State Government.

Part I—the present publication—gives a general picture of State health services, including the extent of dispersion of responsibility among various agencies of State government, the identity of all State agencies participating in health activities, and major changes occurring since 1940 in program content and in the assignment of responsibility.

The tremendous growth in the kinds and volume of health services provided by State governments can be seen in the increase of funds expended and personnel employed. Almost a billion dollars was spent on health in 1949, an increase of about 250 percent over 1940 expenditures. The average per capita expenditure for the 48 States was over \$6, more than three times the corresponding figure for the 1950 survey.

The number of personnel, exclusive of part-time and institutional employees, increased more than 100 percent between 1940 and 1950, with State health departments employing by far the greater numbers.

Perhaps the outstanding disclosure made by this study is the high degree of dispersion of health functions throughout the structure of State governments, which is even more pronounced than at the time of the 1940 survey. In 1950 as many as 32 agencies in a single State were participating in some health activity, contrasted to the top figure of 18 a decade ago. On a nation-wide basis, for a single program there may be as many as 14 distinct types of agencies represented. Although there has been some effort toward consolidation within health departments of programs previously scattered among several agencies, new programs still tend to develop under a variety of auspices.

Tie That Knot

This leaflet was designed as a thumbnail-size guide for planning the location of local health units. It illustrates diagrammatically how public health service areas can be delineated, and how hospital facilities and public health units can be integrated to provide health service coverage for all counties. Comparative statistics on present and suggested future health units are given.

• • •

Tie That Knot. (Public Health Service Publication No. 185) 1952. 2-fold leaflet; illustrated. Available upon request from the Public Inquiries Branch, Public Health Service, Washington 25, D. C.

Report of Local Public Health Resources, 1950

Full-time local health services are basically important in maintaining a healthy population to meet the demands of national defense mobilization, but at the same time these demands are seriously handicapping State and local governments in their efforts to expand and strengthen local health services. This annual report, however, indicates that despite inroads upon personnel, it was possible to continue the operation of most local health units and to expand facilities and services slightly during 1950, although a marked gain in the number of organizations or areas covered was impossible to attain.

This analysis is based upon the "Report of Public Health Personnel, Facilities, and Services" submitted as of December 31, 1950, by 1,193 full-time health organizations providing local health services in 47 States and the District of Columbia. (Vermont has no full-time local health units.) The definition of a full-time local health unit was changed in 1950 to indicate not only the presence of a full-time health officer but also the provision of full-time services.

The report includes data helpful to health administrators in planning for the expansion of local activities. Personnel and selected facilities and services of local health jurisdictions are summarized in terms of the type of agency sponsoring the service. Information is included for all official health agencies providing service to local areas whether they are officially known as a department, unit, commission, or otherwise. Likewise, the analysis includes data on the public health facilities and services available on a free or part-pay basis through official agencies other than health and through voluntary agencies.

Existing full-time health organizations are exceedingly understaffed.

Minimum staffing needs of reporting units approximate an additional 1,000 public health physicians, 10,000 nurses, 16,000 sanitation workers, and 1,400 clerical workers. The small gain (\$00) in total personnel employed in local health departments as of December 1950, compared to June 1949, is encouraging, but the rate of increase is far below that required to meet the demands of complete coverage.

The availability of adequate public health medical facilities is another important need of local health organizations. Certain facilities and services considered basic by most public health officials are not yet included in the program of many health departments. In several of the newer health fields, the official health agency has not undertaken leadership in sponsoring clinical services and facilities, but has depended upon other official agencies or voluntary agencies to supply services.

With respect to sanitation activities even of the most basic types, too many health departments indicate gaps in essential services. Pasteurization of milk has been widely but not yet universally accepted. Approved community sanitation facilities and services are not available to all nonfarm population. The training of food handlers in proper sanitation techniques is included as a health department function in relatively few areas.

Report of Local Public Health Resources, 1950. (Public Health Service Publication No. 232) 1952. 75 pages; tables. Limited number of copies available from the Division of State Grants, Public Health Service, Federal Security Agency, Washington 25, D. C.

Fact Book on Aging

This booklet presents 21 charts and 35 tables on the personal characteristics, income, employment, living arrangements, and health of older persons in the population. Facing each chart is a short statement summarizing its essential meaning and linking the data to facts of related

significance. The tables contain raw data for the charts plus additional information too detailed to be charted. The Fact Book contains basic information necessary for an understanding of the size, distribution, and characteristics of the aging population.

• • •

Fact Book on Aging. Federal Security Agency, Committee on Aging and Geriatrics. 1952. 62 pages; tables; charts. 30 cents. Single copies available on request from Committee on Aging and Geriatrics, Federal Security Agency, Washington 25, D. C.

Cancer Illness Among Residents of Chicago

The sixth in the series of 10 Cancer Morbidity Reports, this study reveals that the cancer incidence among residents of the Chicago area showed no real change from 1937 to 1947. These results differ from those obtained in five previously published studies, dealing with the metropolitan areas of Atlanta, Denver, New Orleans, Pittsburgh, and San Francisco, where more significant increases in cancer incidence were noted.

The study indicates cancer is primarily a disease of middle and late life. Two-thirds of all cancer patients in the Chicago area are over 55 and cancer occurs 100 times as frequently in persons over 65 as in children under 15. The rates are higher among females than among males from about 20 to 60 years of age, but during the early and later years of life the male rates are higher.

Charts and tables show the incidence, prevalence, and mortality rates; age, sex, and color differences; stage at diagnosis; survival rates; and statistics on hospitalization. Increases in reported illness from cancer were particularly noteworthy for the bronchus and lung sites, pancreas, and brain and nervous system. In contrast, reported incidence of cancer of the stomach, liver and biliary passages, and uterus decreased. In women, the most com-

mon cancers are those of the breasts, genital organs, and digestive system; and in men, the digestive system, respiratory system, genital organs, skin, and urinary tract.

• • •
Cancer Illness Among Residents of Chicago, Ill. Cancer Morbidity Series No. 6 (Public Health Service Publication No. 152) 1952. 49 pages; tables; charts. (Not for sale.)

Cancer Illness Among Residents of Dallas, Tex.

Number 7 of the Cancer Morbidity Series reveals that cancer incidence among Dallas City and County residents increased 18 percent from 1938 to 1948, but during the same period cancer mortality for all residents increased only 2 percent. Among men there was an 8-percent increase in mortality and among women a 3-percent decrease.

The importance of early diagnosis is pointed up in the fact that when all cancer sites are considered, 65 percent of the cancer patients in Dallas County were diagnosed while the disease was still localized. When skin cancers are excluded from the total, only half of the remaining cancers were diagnosed while still localized. Ninety-three percent of these patients survived one year or longer. When diagnosis was made after regional involvement, 73 percent survived. Only 35 percent survived, however, when the disease was discovered after remote metastasis had occurred.

As in the previous survey, the Dallas report notes a relationship between cancer and aging. Cancer occurs 100 times as frequently in persons over 65 as in children under 15. On the other hand, 10 percent of all cancer patients in Dallas are under 35. Most common cancers in these younger persons are the leukemias and cancers of the brain and bone.

Following the pattern established in the first six reports, this publication presents charts and tables showing the incidence, prevalence, and mortality rates; age, sex, and color differences; stage at diagnosis; sur-

vival rates; and statistics on hospitalization and cases seen for check-up.

Safe Water

Designed for those living on farms and in small communities which do not have a municipal water supply, this leaflet discusses three types of water systems (well, cistern, and stream), the ways in which they can become polluted, and how such pollution can be prevented. The reader is advised to consult his local health department to learn how he can protect his water supply from dangerous disease germs.

• • •
Safe Water. Community Health Series, No. 2 (Public Health Service Publication No. 71) 1951. 3-fold leaflet. Illustrated. 5 cents; \$1.50 per 100.

A Healthy Personality for Your Child

Written for parents to give them an understanding of the stages through which children grow emotionally from infancy to adulthood, this new publication of the Children's Bureau, Federal Security Agency, is a popular version of a part of the fact finding report prepared for the Midcentury White House Conference on Children and Youth.

The original report was the product of a committee which included doctors, psychologists, anthropologists, social workers, clergymen, delinquency experts, lawyers, educators, and specialists in youth employment, recreation, and child development. The popular version was written by Dr. James L. Hymes, Jr., professor of education, George Peabody College for Teachers, Nashville, Tenn.

"A Healthy Personality for Your Child" puts together what is gener-

ally accepted by authorities on how personality grows and how it is shaped. Beginning with infancy, it discusses the emotional needs of children, their attitudes and reactions, and the changes they go through during the years up to post-adolescence. It is agreed that parents are the most important influence in their children's lives. Their role in shaping the children's personalities is discussed in relation to the various stages of development.

NOTE: A discussion aid, based on this pamphlet, for use of parents groups interested in exploring problems of emotional growth is available from the Children's Bureau without charge.

• • •
A Healthy Personality for Your Child. Children's Bureau, Federal Security Agency. Publication No. 337. 1952. 23 pages. Illustrated. Single copies available without charge, so long as the supply lasts, on request to the Children's Bureau, Federal Security Agency, Washington 25, D. C.

Safe and Sanitary Home Refuse Storage

As noted in the article "Refuse-Can Holders" in the August issue of *Public Health Reports*, this leaflet contains recommendations concerning the proper storage of home refuse. Stressing the protection to be gained against disease, accident, fires, and vermin, it outlines five simple steps for the householder. They are: (1) providing and using proper containers; (2) maintaining the containers in a sanitary condition; (3) placing the containers in the right place at the right time; (4) draining garbage and bundling bulky rubbish; and (5) where required, separating garbage, ashes, and rubbish. These steps are further amplified, with suggestions on types of storage cans and stands to set them on.

• • •
Safe and Sanitary Home Refuse Storage. (Public Health Service Publication No. 183) 1952. 2-fold leaflet, illustrated. 5 cents; \$1.00 per 100 copies.

Health Manpower Source Book

Section I—Physicians

To meet the frequent requests for information on medical manpower, the Division of Public Health Methods, in cooperation with the Divisions of Dental, Nursing, and Engineering Resources, is preparing a comprehensive source book on health manpower. The first section of the source book, issued as a preliminary report, is concerned with physicians. It is based on material published periodically by the American Medical Association and upon various special surveys. The final report on physicians and about 18 other occupations in the health industry will include 1950 census data which are not yet available.

The preliminary report is composed almost exclusively of statistical tables on the country's physicians — geographic distribution, type of specialty, licensure information, graduates over a period of years, income, average patient load, data on group practice. There are 66 tables and the bibliography lists 132 references.

The estimated number of physicians in the continental United States at the end of 1951 was about 211,000, according to the American Medical Association and reported in the Source Book. In 1949 there were 121 active non-Federal physicians for every 100,000 civilian population. This is a slight decrease from the 1940 rate of 122 physicians per 100,000 population. There has been an increase in the numbers of physicians who reported a practice limited to a specialty. The Source Book points out that in 1949, nearly 63,000 (31 percent) reported that they were full-time specialists, in contrast to 11 percent in 1923 and 21 percent in 1940. Internal medicine, surgery, and ophthalmology-otolaryngology accounted for more than half of the total specialists.

Health Manpower Source Book, Section I, Physicians, Preliminary. (Public Health Service Publication No. 263) May 1952. 70 pages, tables. 40 cents.

for the general public

Smallpox

The emphasis in this health information leaflet is on vaccination. The story of early epidemics and the development of our present form of immunization are reviewed. Facts about the disease include how it is spread, symptoms, and medical care. The list of precautions gives details on vaccination, when it should be done, and how often it should be repeated. Prompt reporting of cases of chickenpox is urged, as smallpox is often mistaken for the more mild disease.

Smallpox. Health Information Series, No. 27 (Public Health Service Publication No. 230). Reprinted 1952. 1-fold leaflet. 5 cents; \$1.25 per 100.

Sunstroke, Heatstroke, Heat Prostration

Because of the number of people who succumb to so-called thermic fever, this leaflet is of particular importance during the summer months. It describes the three illnesses, their causes, and symptoms. First-aid instructions are given, stressing the importance of calling a doctor at once. Common-sense precautions for hot weather are given and the need for extra water and salt is discussed.

Sunstroke, Heatstroke, Heat Prostration. Health Information Series, No. 4 (Public Health Service Publication No. 176). Revised 1952. 1-fold leaflet. 5 cents; \$1.25 per 100.

Home Care of the Sick

Since a majority of the persons who are sick in the United States today are cared for in the home, this leaflet presents valuable general information for the person giving home

care. It covers the selection of the patient's room, the furnishings, sick-room equipment, bed and bed clothing. Instructions are given for changing patient's bed linen and for the preparation of the patient for the day. The leaflet also discusses the handling of communicable disease cases, and ways in which the attendant can be of help to the physician. Organizations and individuals who can give instructions in nursing care are suggested.

Home Care of the Sick. Health Information Series, No. 21 (Public Health Service Publication No. 70). Third printing, May 1952. 2-fold leaflet. 5 cents; \$1.50 per 100.

Hay Fever

Hay fever is more than just an annoyance—it can be serious. This health information leaflet describes hay fever, its symptoms, and the various types of seasonal hay fevers. It discusses the diagnosis of hay fever by means of allergy tests, and treatment with injections and medicines. Other means of obtaining relief suggested are the removal of pollens from the air of the victim's room or a change of location. However, the reader is advised that a doctor should be consulted lest the patient leave one type of pollen only to encounter another to which he is sensitive.

Hay Fever. Health Information Series, No. 17 (Public Health Service Publication No. 208). Revised 1952. 1-fold leaflet. 5 cents; \$1.75 per 100.

Publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication (including its Public Health Service publication number). Single copies of most Public Health Service publications can be obtained without charge from the Public Inquiries Branch, Public Health Service, Washington 25, D. C.
